Vol. I

TRANSCRIPT OF RECORD

(Pages 1 to 500)

Supreme Court of the United States

OCTOBER TERM, 1944

No. 50

THE DOW CHEMICAL COMPANY, PETITIONER,

vs.

HALLIBURTON OIL WELL CEMENTING COMPANY

No. 61

HALLIBURTON OIL WELL CEMENTING COMPANY, PETITIONER,

vs.

THE DOW CHEMICAL COMPANY

ON WRITS OF CERTIORARI TO THE UNITED STATES CIRCUIT COURT OF APPEALS FOR THE SIXTH CIRCUIT

PETITIONS FOR CERTIORARI FILED {APRIL 6, 1944.
APRIL 17, 1944.

CERTIORARI GRANTED MAY 15, 1944.

Supreme Court of the United States

OCTOBER TERM, 1944

No. 50

THE DOW CHEMICAL COMPANY, a Corporation,
Petitioner,

vs.

HALLIBURTON OIL WELL CEMENTING COMPANY,
a Corporation,
Respondent.

TRANSCRIPT OF RECORD

On Petition for Writ of Certiorari to the United States Circuit Court of Appeals for the Sixth Circuit

Volume I—Pages 1 to 500

WILBER OWEN,
1601 Nicholas Building, Toledo, Ohio,
CALVIN A. CAMPBELL,
The Dow Chemical Company,
Midland, Michigan,
RUSSELL WILES,
Board of Trade Bldg., Chicago, Illinois,
DONALD L. CONNER,
The Dow Chemical Company,
Midland, Michigan,
Attorneys for Petitioner.

EARL BABCOCK,
Duncan, Oklahoma,
LEONARD S. LYON,
811 West 7th Street,
Los Angeles, California,
Attorneys for Respondent.

IN THE

UNITED STATES CIRCUIT COURT OF APPEALS

FOR THE SIXTH CIRCUIT

No.....

THE DOW CHEMICAL COMPANY, A CORPORATION,
Plaintiff-Appellant,

vs.

HALLIBURTON OIL WELL CEMENTING COMPANY,
A CORPORATION,
Defendant-Appellee.

Appeal from the United States District Court for the Eastern District of Michigan, Northern Division

---

CALVIN A. CAMPBELL,
The Dow Chemical Company,
Midland, Michigan,
Attorney for Plaintiff.

WILBER OWEN,
1601 Nicholas Building, Toledo, Ohio,

RUSSELL WILES,
Board of Trade Bldg., Chicago, Illinois,

DONALD L. CONNER,
The Dow Chemical Company,
Midland, Michigan,
Of Counsel for Plaintiff.

EARL BABCOCK,
Duncan, Oklahoma,
Attorney for Defendant.

LEONARD S. LYON,
811 West 7th Street,
Los Angeles, California,
Of Counsel for Defendant.

INDEX TO VOLUMES I, II AND III

	Pages
Complaint	2, 3
Amended Answer of Defendant	4–12
Counterclaim	13
Stipulation re Previous Litigation	13, 14
Offers of Exhibits	1403, 1408, 1425, 1434
Proceedings on Settlement of Findings of Fact	1435–1477
Findings of Fact	1478–1491
Conclusions of Law	1492
Decree	1492–1493
Notice of Appeal	1494
Orders Extending Time	1494–1495
Stipulation Extending Time	1496
Statement of Points on Which Appellant Will Rely	1497–1500
Stipulation Approving Printed Record on Appeal	2048

	Watts article (1912)	89	1587
	Corbett article (1918)	93	1588
12	Summary of Dow Shipments of acid with inhibitors February 11 to November 10, 1932	113	1591–96
13	Letters, dated June 13, 1932, to January 19, 1933, from oil industry inquiring about new Dow process of acid treatments for oil wells	148	1597–1625
14	Item in Midland paper regarding new Dow well treating process, dated June 9, 1932	148	1626

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Pages Printed
19	First invoice of defendant for acidizing well, dated March 11, 1935.....	248	1627
20	Second invoice of defendant for acidizing well, dated May 25, 1935.....	248	1628
21	Third invoice of defendant for acidizing well, dated May 25, 1935.....	248	1628
23	Purchase order from Erle P. Halliburton, Inc., dated 5/21/34, for acid treatment of well by Dowell, Inc.....	250	1629
26	Ditto, dated October 24, 1934.....	250	1630
27	Bulk material sales receipt for 1,000 gal. Dowell X acid delivered by Dowell Inc., to Erle P. Halliburton, Inc., dated November 9, 1934.....	250	1631
31	Agreement dated March 15, 1934, for acidizing two wells by Dowell, Inc., for Steen Drilling, Inc.....	251	1632
34	Agreement dated April 20, 1934, for acidizing ten wells by Dowell, Inc., for Steen Drilling, Inc., or Erle P. Halliburton, Inc.	251	1635
38	Order from Steen Drilling, Inc., dated 3/15/34, for acid treatment by Dowell, Inc.	254	1639
40	Ditto, dated 3/17/34.....	254	1639
43	Ditto, dated 4/20/34.....	254	1640
46	Purchase order from Erle P. Halliburton, Inc., dated 5/9/34, for 2,000 gal. acid job by Dowell, Inc.....	254	1640
52	Receipt, dated 7/10/34, for well treatment performed by Dowell, Inc., for Erle P. Halliburton, Inc.....	254	1641
54	Ditto, dated 7/24/34.....	254	1642
57	Ditto, dated 8/15/34.....	254	1643
59	Ditto, dated 9/16/34.....	254	1644
60	Purchase order from Steen Drilling, Inc., dated 9/16/34, for 1,500 gal. acid job by Dowell, Inc.....	254	1645
62	Receipt, dated 10/24/34, for well treatment performed by Dowell, Inc., for Erle P. Halliburton, Inc.....	254	1646
64	Ditto, dated 11/14/34.....	254	1647
66	Ditto, dated 12/19/34.....	254	1648
67	Stipulation re testimony of R. E. Heithecker.	213	Vol. I, 213
68	Stipulation re testimony of H. C. Miller	235	Vol. I, 235

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
71	Sketches of defendant's truck tank...	262	1649
93	Article in Oil City Derrick of October 10, 1895, entitled "A Great Discovery," reporting acid treatment of well by Frasch and Van Dyke.....	1194A	1651–54
94	Table of Dowell, Inc., statistics showing growth from November 10, 1932, to 1940, inclusive. (See also Plaintiff's Exhibit 232.).....	161	1655
99	Well completion data Greendale (Michigan) oil field.....	168	Vol. I, 168
142	Carnegie Library Card cataloging available issues of Oil City Derrick...	1194A	1656
143	Item in Oil City Derrick for October 28, 1895, reporting acid treatment of wells by Frasch and Van Dyke.....	1194A	1656
144	Ditto, for November 9, 1895.....	1194A	1657
145	Ditto, for January 15, 1896.....	1194A	1658
146	Ditto, for February 20, 1896.....	1194A	1659
147	Ditto, for February 22, 1896.....	1194A	1661
148	Ditto, for March 26, 1896.....	1194A	1661
149	Ditto, for August 10, 1897.....	1194A	1663
150	Stipulation re Williams Bros. record..	13	Vol. I, 13
153	Gypsy Oil Company correspondence and reports re removal of "Gyp" scale and prevention of formation of "Gyp" in oil wells of the Glenpool, Okla., field	1087	1664–1704
154	Bartell Table showing results of corrosion tests with defendant's truck (treating) acids on strap iron test pieces	329	1705
155	Ditto, showing results on test pieces of oil well pipe from National Supply Co.	333	1706
156	Ditto, showing results on test pieces of oil well pipe from Oil Well Supply Co.	333	1707
157	Ditto, showing results on test pieces of oil well pipe from Atha Supply Co..	334	1708
158	Bartell Table showing results of corrosion tests with defendant's storage acids on strap iron test pieces.....	345	1709
159	Ditto, showing results on test pieces of oil well pipe from National Supply Co.	345	1710

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
160	Bartell Table showing analyses of defendant's truck (treating) acid samples	376	1711
161	Bartell Table showing analyses of acid samples taken from defendant's storage tanks	378	1712
162	Bartell Table showing analyses of acid samples taken from defendant's storage tanks and diluted to strength of defendant's truck (treating) acid samples	379	1712
163	Bartell Table showing content of copper, lead and iron in acid used by defendant in treating Zahn well, and same as to acid from defendant's storage tanks	380	1713
164	Bartell Table showing content of copper, lead and iron in acid used by defendant in treating Stella Wilcox well, and same as to acid from defendant's storage tanks	383	1714
165	Bartell Table showing content of copper, lead and iron in acid used by defendant in treating Crawford well, and same as to acid from defendant's storage tanks	384	1715
166	Bartell Table showing results of corrosion tests using c. p. (chemically pure) hydrochloric acid solution containing different amounts of copper, lead and iron	394	1716
167	Bartell Table showing effect of agitation and increased quantity of acid on corrosiveness of acid solutions containing different amounts of copper, lead and iron	407	1719
169	Bartell Table showing amounts of copper, lead and iron in defendant's truck (treating) tank acids and storage tank acids	424	1720
170	Bartell's chart showing effect of adding copper, lead and iron to 15.1% c. p. hydrochloric acid	428	1721

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
171	Bartell Table showing percentage reduction in corrosiveness of hydrochloric acid resulting from addition of different inhibitors named in Grebe-Sanford patent	451	1723
172	Data showing dates when samples of defendant's treating and storage acids were taken by plaintiff and dates of receipt of acid by defendant	494	1724
173A	Prutton Table showing results of small scale tests of corrosiveness of hydrochloric acid containing different amounts of iron, lead and copper	516	1726
173B	Table comparing results of some of tests shown in Exhibit 173A	516	1727
173C	Ditto	516	1727
173D	Ditto, and description of tests, materials and equipment used and explanation of tables	516	1728–33
176	Prutton Table showing amount of iron dissolved from Series 1 oil well tubing in large scale Run 1A using 15% commercial HCl	508	1734
177	Ditto re Run 1AA	515	1735
178	Ditto re Run 2A using Series 2 tubing	515	1736
179	Ditto re Run 2C using Series 2 tubing	515	1737
180	Ditto re Run 1B using Series 1 tubing and 15% commercial HCl containing small amounts of copper, lead and iron chlorides	517	1738
181	Ditto re Run 2B. Similar to Run 1B, but with Series 2 tubing	517	1739
182	Ditto re Run 2D. Similar to Run 2B, but with different amounts of copper, lead and iron	517	1740
183	Ditto re Run 2E. Similar to Run 2B, but with different amounts of copper, lead and iron	517	1741
184	Prutton's summary and conclusions with respect to runs in Exhibits 176-183	534	1742–45
185	Prutton Tables showing results of Runs 1M, 1N, 2M and 2N, using commercial acid from special tank embodying features of defendant's truck tanks	537	1746–49
	Sketch showing equipment used in Runs 1M, 1N, 2M and 2N	537	1751

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
186	Defendant's booklet re Howco method	587	Vol. II, 587
187	Prutton graph showing results of runs of Exhibits 176-183	602	1752
188	Prutton graph comparing results of Runs 1M, 1N, 2M and 2N (Exhibit 185) with average of Runs 1A, 1AA, 2A and 2C (Exhibits 176-179)	604	1753
189	Prutton graph showing results of tests of 15% c. p. hydrochloric acid with different added amounts of copper, lead and iron	605	1754
192	History of oil development in limestone fields prior to 1932 and history of acidizing in those fields beginning in 1932, prepared by the witness Fitzgerald	178	1755–70
195	Item from Montana Oil & Mining Journal for January 26, 1935, reporting increase of production in Pondera (Montana) field, due to acidizing	186	1770
196	Bulletin of Montana Oil Conservation Board	189	Vol. I, 187
199	Letter, Dow Co. to Oil Makers, 9-23-32	1171	Vol. III, 1172
200	Letter, Grasselli to Oil Makers, 10-14-32.	1174	Vol. III, 1174
201	Letter, Grasselli to Oil Makers, 11-1-32.	1175	Vol. III, 1175
202	Letter, Grasselli to Oil Makers, 1-26-33.	1176	Vol. III, 1178
203	Letter, Grasselli to Oil Makers, 9-15-32.	1179	Vol. III, 1179
204	Letter, Oil Makers to Grasselli, 10-8-32.	1179	Vol. III, 1180
205	Oil Makers checks to Penn. Salt Co.	1196	Vol. III, 1196
216	Letter, Lee to Oil Makers, 2-7-33	1243	Vol. III, 1242
218A-218D	Pages from notebook kept by the witness Sprenger	1257	1772–74
219, 220	Photograph of standing valve and working valve	1268	1775
228	Letter, Prutton to Rebbeck, 1-28-41	799	1776
231A-231J	Dow Company's records of shipments of acid to Pure Oil Company during period from February to May, inclusive, 1932	140	1777–86
232	Table supplementing Exhibit 94	845	1787
233	Summary of well treatments made by licensees of Dow other than Dowell	845	1788

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
234	Sketch and data prepared by Dr. Prutton showing rates of attack on oil well tubing of 15% c. p. hydrochloric acid and of 15% synthetic defendant's treating acid	840	1789
242	Dowell advertisement in Petroleum World, September, 1938	846	1790
243	Ditto for January, 1939	847	1791
245	Dowell, Inc., Service Price Schedule 110.	852	1792
246	Record of shipments of hydrochloric acid and arsenic inhibitor by Dow Company for period January to June, 1932, inclusive	121	1793
305	Affidavit of Robert Quinlan on the first treatment of a Pure Oil Company well with inhibited hydrochloric acid	1028	1794
328	Table showing results of acid treatments of gas wells by Dowell, Inc., prepared by the witness Lyons	191	1796
329	Ditto, showing additional treatments and data	193	1797
330	Table showing time acid was in tubing in each of 122 acid treatments made by Dowell in Kansas from March to September, 1936, in 97 consecutive Arbuckle dolomite wells	197	1798
331	Data showing average time acid was in tubing in making the 122 treatments itemized in Exhibit 330	197	1799
337	Chart showing combinations possible under claims of Gravell Patent 1,678,775.	1320	1800
343	Alquist Table showing rate of corrosion of mild steel in various concentrations of hydrochloric acid	1365	1801
	Charts forming part of Exhibit 343	1365	1802–03
344	Alquist Table showing acceleration of the rate of corrosion of hydrochloric acid containing an acid regulator caused by the addition of tin, cobalt or nickel	1370	1804
	Chart forming part of Exhibit 344	1370	1805
347	Table supplementing Plaintiff's Exhibit 252	1404	1806
348	Table showing treatments by Dow licensees other than Dowell	1404	1807

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
349	Table showing summary of royalty charged by Dow Company to licensees.	1404	1808
350	Table showing quantities of inhibited acid and other materials used by Dowell, Inc.	1405	1809
350A	Graph illustrating data in Exhibit 350.	1407	1810
351	Acidizing orders, tickets and other data from defendant's files relating to wells at which plaintiff secured samples of defendant's truck (treating) acids	1406	1811–24
354	Dowell advertising data for years 1932 to 1934	1407	1825
355	Photograph of one-half gallon container used in Alquist's tests, and table and graphs showing results of tests.	1376	1827–29
356	Photographs of 10-gallon drum and of equipment used by Alquist in making tests, and tables and graphs showing results of such tests	1380	1830–40
357	Table, graphs and drawing of equipment used by Alquist in making tests showing loss of strength of 15% hydrochloric acid when in contact with iron for different periods up to 24 hours.	1398	1841–46
358	Bartell Table showing summary of corrosion tests of various commercial hydrochloric acids of 15.1% strength..	499	1847
360	Table showing Dowell advertising 1932 to 1940, inclusive	1408	1848
362	Poffenberger's report on acid treatment of Dow Company's brine well No. 77	1418	1849-53
363	Poffenberger's report on acid treatment of Dow Company's brine well No. 80	1418	1854
364	Poffenberger's report on tests of inhibiting value of arsenic compounds in hydrochloric acid	1423	1855
366	Carr and Humphrey patent application for method for increasing fluid production from oil wells	1427	1857–64

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Number Exhibit		Identified	Printed Pages
367	Carr and Humphrey patent application on chemical reagent for use in oil wells	1428	1864–68
368	Carr and Humphrey patent application for method for introducing acid reagents into oil wells by gas pressures	1428	1868–72
369	Agreement between The Dow Chemical Company and The Pure Oil Company dated January 31, 1933	1428	1873–77
370	Agreement between The Dow Chemical Company and The Pure Oil Company dated June 30, 1934	1428	1877–82

DEFENDANT'S EXHIBITS

8	Excerpts from article by R. Van A. Mills, dated December, 1923, entitled "The Paraffin Problem in Oil Wells".	35	1883
72	Letter from M. G. Harper to J. W. Van Dyke, dated December 5, 1895	1033	1884
73	Telegram, Harmon to Van Dyke, dated January 24, 1896	1033	1885
74	Memo from C. F. Lufkin to Van Dyke, undated	1033	1886
83	Telegram, J. C. Donnell to Van Dyke, dated November 25, 1895		1887
86	Telegram, Harper to Van Dyke, dated December 6, 1895		1887
88	Letter, The Grasselli Chemical Company to Van Dyke, dated July 26, 1895		1888
90	Letter, Herman (Frasch) to Van Dyke, dated September 22, 1895		1889
101	Letter, Harper to Van Dyke, dated December 16, 1895	1033	1890
102	Letter, Harper to Van Dyke, dated December 16, 1895	1047	1891
103	Letter, Ohio Rubber Company to Solar Refining Co., dated September 21, 1895	1047	1892
104	Letter, Ohio Rubber Company to Solar Refining Co., dated September 25, 1895		1893
105	Memo re Crossley Well No. 3 of Ohio Oil Company	1047	1894

All exhibits are printed in Volume IV unless otherwise indicated.

IN THE

United States District Court

EASTERN DISTRICT OF MICHIGAN

NORTHERN DIVISION

Pleadings and proceedings before the Honorable Arthur J. Tuttle, Judge of the United States District Court for the Eastern District of Michigan, in the following entitled cause:

No. 45

THE DOW CHEMICAL COMPANY, A CORPORATION,
Plaintiff.

vs.

HALLIBURTON OIL WELL CEMENTING COMPANY,
A CORPORATION,
Defendant.

COMPLAINT

(Filed June 15, 1939)

(1) This is an action for infringement of United States Letters Patent.

(2) Jurisdiction is founded on the Patent Laws of the United States.

(3) Plaintiff is a corporation created and existing under the laws of the State of Michigan, and has a principal place of business at Midland, Michigan.

(4) Defendant is a corporation created and existing under the laws of the State of Delaware, having a principal place of business at Duncan, Okla., licensed to do business in the State of Michigan, and having a regular and established place of business at Mt. Pleasant, Isabella County, Michigan, within the Eastern District of Michigan, Northern Division, where, and elsewhere, it has committed the acts herein complained of.

(5) Letters Patent of the United States were duly and regularly issued to plaintiff as follows:

No. 1,877,504, on September 13, 1932, for "Treatment of Deep Wells," as assignee of John J. Grebe and Ross T. Sanford, both of Midland, Michigan.

(Here are listed three other patents that are not involved in the appeal, viz., Grebe 1,916,122, for Method of Treating Wells with Acid; Grebe and Stoesser 1,998,756, for Treatment of Deep Wells, and Chamberlain 2,024,718, for Treatment of Wells.)

Proffert of said Letters Patent, or duly certified copies thereof, is hereby made.

(6) Since the dates of issuance of said Letters Patent plaintiff has been and still is the owner thereof.

(7) Letters Patent No. 1,877,504, aforesaid, were held valid and infringed by the United States Circuit Court of Appeals for the Tenth Circuit, in the case of The Dow Chemical Company vs. Williams Brothers Well Treating Corporation. (81 Fed. 2d 495.)

(8) Defendant for some time past, and within six years prior to the filing of this suit, has been and still is infringing said Letters Patent, and each of them, by practicing, in the Eastern District, Northern Division, of Michigan and elsewhere within the United States, the process of treating wells disclosed and claimed in said Letters Patent, and each of them, and particularly in Claims Nos. 1, 5, 7, 8 and 9 of Letters Patent No. 1,877,504; and will continue to do so unless enjoined by this court.

(9) Defendant has been notified of plaintiff's ownership of said Letters Patent, and each of them, and of its infringements thereof, and notwithstanding said notice defendant has continued said infringements.

Wherefore, plaintiff demands a preliminary and a final injunction against further infringement by defendant and those controlled by defendant, an accounting of profits and damages, and an assessment of costs against defendant.

AMENDED ANSWER OF DEFENDANT

(Filed Sept. 11, 1940)

Defendant, Halliburton Oil Well Cementing Company, answering the Complaint, filed on or about June 15, 1939, of the Dow Chemical Company, Plaintiff, says:

1. Answering Paragraph 1 of the Complaint, defendant admits that this is an action for infringement of Letters Patent.

2. Answering Paragraph 2 of the Complaint, defendant admits the jurisdiction of this Honorable Court.

3. Answering Paragraph 3 of the Complaint, defendant admits that plaintiff is a corporation created and existing under the laws of the State of Michigan and has a principal place of business at Midland, Michigan.

4. Answering Paragraph 4 of the Complaint, defendant admits that defendant is a corporation created and existing under the laws of the State of Delaware; that it has a principal place of business at Duncan, Oklahoma; and that it is licensed to do business in the State of Michigan and has a regular and established place of business at Mt. Pleasant, Isabella County, Michigan, within the Eastern District, Northern Division. Defendant denies that it has committed the acts complained of in the Complaint.

5. Answering Paragraph 5 of the Complaint, defendant admits that on September 13, 1932, United States Letters Patent No. 1,877,504 were issued to plaintiff, as assignee of John J. Grebe and Ross T. Sanford, for "Treatment of Deep Wells" but denies that said Letters Patent were duly and regularly issued.

* * * * *

6. Answering Paragraph 6 of the Complaint, defendant admits that since the dates of issuance of the several patents in suit the plaintiff has been, and was at the date of the filing of this action, the owner of said patents.

7. Answering Paragraph 7 of the Complaint, defendant admits that Letters Patent No. 1,877,504 aforesaid,

were involved in litigation in the case of The Dow Chemical Company vs. Williams Brothers Well Treating Corporation in the United States Circuit Court of Appeals for the Tenth Circuit (81 F. (2d) 495), but asserts that there is no connection whatever between the defendant in that case and the defendant herein and asserts that defendant herein is not using the agents for inhibiting corrosion claimed to have been used by the Williams Brothers Well Treating Corporation, or any of the agents for inhibiting corrosion referred to and defined in the claims of Letters Patent 1,877,504, in suit. Defendant denies that all the claims of Letters Patent 1,877,504 aforesaid, were held valid by the United States Circuit Court of Appeals for the Tenth Circuit and asserts, particularly, that Claim 9 of said Letters Patent 1,877,504, one of the claims charged to be infringed herein, was not before the United States Circuit Court of Appeals for the Tenth Circuit in the case of The Dow Chemical Company vs. Williams Brothers Well Treating Corporation, supra.

8. Answering Paragraph 8 of the Complaint, defendant denies that it has at any time infringed, and denies that it is now infringing, the aforesaid Letters Patent, or either of them, by practicing in the Eastern District, Northern Division of Michigan, or elsewhere in the United States, processes embodying the alleged patented inventions, and particularly claims 1, 5, 7, 8 and 9 of Letters Patent 1,877,504, and defendant denies that it will infringe any of said Letters Patent unless enjoined by this court.

9. Answering Paragraph 9 of the Complaint, defendant denies that it has been notified of plaintiff's ownership of said Letters Patent, or any of them, and denies that it has been notified of the alleged infringement of any of said Letters Patent and defendant denies that, notwithstanding notice, it has committed any acts of infringement.

Further answering the Complaint:

10. Defendant avers that plaintiff has asserted, and is asserting in this action, a broad and dominating monopoly wholly unsupported by any invention made by the alleged

inventors of the Letters Patent in suit, and wholly unsupported by any invention disclosed by the patents in suit.

11. Defendant avers that it is not using any invention claimed, or even disclosed, by any of the Letters Patent in suit. On the contrary, defendant is utilizing methods developed or designed by others than the patentees in the patents in suit. Defendant is utilizing, among others, methods described and covered by the following Letters Patent of the United States issued to defendant as assignee:

No. 2,122,483, Paul L. Menaul, July 5, 1938, "Methods and Means for Acidizing Wells";

No. 2,149,617, Paul L. Menaul, March 7, 1939, "Methods and Apparatus for Handling Acidic Solutions."

12. Defendant avers upon information and belief that the Letters Patent in suit, and particularly the claims thereof herein charged to be infringed, and each of them were so restricted and limited in scope by the procedure in the Patent Office prior to the issuance of said Letters Patent that such claims, and each of them, if valid at all, are not entitled to a construction which will include or cover any device, composition of matter or process made, sold, used or practiced by defendant; wherefore, defendant denies infringement of any of the claims of said Letters Patent.

13. Defendant avers upon information and belief that the claims of the Letters Patent in suit herein charged to be infringed cover mere aggregations or old combinations of method steps and not new patentable methods and are, therefore, invalid under the law.

14. Defendant alleges upon information and belief that the claims of the Letters Patent in suit herein charged to be infringed distinguish over the prior art existing at the time of the alleged inventions only by the substitution of known equivalent steps in the methods of the prior art.

15. Defendant alleges upon information and belief that the patentees of Letters Patent 1,877,504 in suit surreptitiously and unjustly obtained the patent for things which are in fact the invention of W. A. Thomas of Sagi-

naw, Michigan, now of Mt. Pleasant, Michigan, who was using reasonable diligence in adapting and perfecting the same.

16. Defendant avers upon information and belief that the claims of Letters Patent 1,877,504, charged to be infringed by this defendant, are invalid and void and of no effect for the following reasons:

(a) That the methods described and claimed in each of said claims, respectively, or material and substantial parts thereof, were patented or described in printed publications prior to the alleged invention or discovery thereof by the patentees of the patent in suit, or more than two years prior to their application for Letters Patent therefor, as follows:

Chemical and Metallurgical Engineering, July, 1927, Vol. 34, No. 7, pp. 421-424, articles entitled "Practical Application of Inhibitors in Pickling Operations" by Speller & Chappell, and "Removing Rust from System with Piping Acid" by Speller, et al;

Principles of Electrochemistry by Blum and Hogaboom (First Edition) (pages 64-67);

Bureau of Mines Technical Paper No. 15, (1913), entitled "An Electrolytic Method of Preventing Corrosion of Iron and Steel" by J. K. Clement and L. V. Walker

and also other patents and printed publications, the names, numbers, dates and authors of which are not at present known to defendant, but which when ascertained defendant prays leave to add hereto.

(b) The methods described and claimed in each of the claims of Letters Patent 1,877,504 in suit do not involve invention over the prior art cited in paragraph (a) hereof, but represent, at most, the exercise of mere skill in the art.

(c) The patentees of Letters Patent 1,877,504, in suit, were not the original and first inventors or discoverers of the things patented thereby, or of any material or substantial part thereof, but prior to the alleged invention thereof by the said patentees of said Letters Patent, the same were, if invention be involved therein, invented by or known to the patentees listed in paragraph (a) hereof, at the addresses given in the Letters Patent and applications involved, and by:

Muskegon Oil Corporation, Muskegon, Michigan;

Gulf Oil Corporation, Pittsburgh, Pennsylvania, and its subsidiaries;

Grasselli Chemical Company, Cleveland, Ohio;

Ohio Oil Company, Cleveland, Ohio;

Solar Refining Company, Lima, Ohio; and
American Chemical Paint Company, Ambler, Pennsylvania,
Gulf Oil & Refining Company, Pittsburgh, Pennsylvania

and also by others not now known to defendant, but which when ascertained, defendant prays leave to add hereto.

(d) That prior to the alleged invention by the patentee in Letters Patent 1,877,504 in suit, or more than two years prior to the filing of the application for said Letters Patent, the alleged invention thereof had been in public use or on sale in the United States by:

Muskegon Oil Corporation, Muskegon, Michigan, at or near Muskegon, Michigan;
Gulf Oil Corporation, Pittsburgh, Pennsylvania and its subsidiaries, in or near Lee County, Kentucky; in or near Claiborne Parish, Louisiana; and in various places in Oklahoma;
Grasselli Chemical Company, Cleveland, Ohio, at East Chicago, or Grasselli, Indiana;
Ohio Oil Company, Cleveland, Ohio, at or near Lima, Ohio and Findlay, Ohio;
American Chemical Paint Company, Ambler, Pennsylvania, at Ambler, Pennsylvania;
Gulf Oil & Refining Company, Pittsburgh, Pennsylvania at Homer, Louisiana,

and by the patentees listed in paragraph (a) hereof, at the addresses given in their respective patents and applications therefor, and also by others not now known to defendant, but which when ascertained, defendant prays leave to add hereto.

(e) That Letters Patent 1,877,504 are invalid and void because granted by the Patent Office through inadvertence, accident or mistake. Defendant alleges that the Primary Examiner was interviewed during the pendency of the application which matured into Letters Patent 1,877,504, while the Assistant Examiner, who was an expert in the art, was away on his vacation. At this interview the Ex-

aminer was given to understand, intentionally or otherwise, that, contrary to the facts, the prior art did not disclose the use of hydrochloric acid for the treatment of oil wells. The Examiner informed counsel, in writing, of this understanding. Counsel did not correct the Examiner's mistaken views, but immediately paid the final fee and had the patent issued.

(f) That the invention or discovery purported to be covered by Letters Patent 1,877,504 alleged to have been the joint invention of John J. Grebe and Ross T. Sanford was in fact the sole invention of John J. Grebe only.

(g) That the invention or discovery purported to be covered by Letters Patent 1,877,504 alleged to have been the joint invention of John J. Grebe and Ross T. Sanford was in fact the sole invention of Ross T. Sanford only.

(h) That the invention or discovery purported to be covered by Letters Patent 1,877,504 alleged to have been the joint invention of John J. Grebe and Ross T. Sanford was in fact the joint invention of John J. Grebe, Ross T. Sanford and W. A. Thomas.

(i) That the invention or discovery purported to be covered by Letters Patent 1,877,504 alleged to have been the joint invention of John J. Grebe and Ross T. Sanford was in fact the joint invention of John J. Grebe and W. A. Thomas.

(j) That the invention or discovery purported to be covered by Letters Patent 1,877,504 alleged to have been the joint invention of John J. Grebe and Ross T. Sanford was in fact the joint invention of Ross T. Sanford and W. A. Thomas.

Wherefore defendant prays that said Letters Patent No. 1,877,504, be declared invalid and of no force or effect; that defendant be decreed to not infringe the aforesaid Letters Patent; that costs herein be taxed against the plaintiff; and that the Complaint herein be dismissed, and for such other and different relief as to the court may be just and equitable.

COUNTERCLAIM

The Answer included a Counterclaim based on Gravell Patent 1,678,775, issued July 31, 1928, for storage and transportation of acid mixtures in steel drums, which counterclaim was dismissed and no appeal taken therefrom.

STIPULATION RE PREVIOUS LITIGATION

The following stipulation was entered into with respect to previous litigation on Grebe and Sanford Patent No. 1,877,504:

"1. That suit was brought by the Dow Chemical Company vs. Williams Brothers Well Treating Corporation, on or about the 24th day of April, 1934, for the alleged infringement of United States Patent to Grebe et al., No. 1,877,504.

"2. That said suit came on for trial in the United States District Court for the Northern District of Oklahoma, before the Honorable Judge F. E. Kennamer, during the month of September, 1934.

"3. That by final decree on or about January 15, 1935, the Bill of Complaint was dismissed.

"4. Plaintiff, The Dow Chemical Company, thereupon took an appeal to the United States Circuit Court of Appeals for the Tenth Circuit, which appeal was docketed as No. 1285.

"5. That the decision of the Tenth Circuit Court of Appeals was as reported in 81 Fed. (2d) 495.

"6. That for the purposes of this stipulation, the transcript of testimony and the copies of exhibits printed in the transcript of record on appeal to said United States Circuit Court of Appeals, for the Tenth Circuit, entitled 'The Dow Chemical Company, Appellant, vs. Williams Brothers Well Treating Corporation, Appellee,' shall be considered as being true, complete and correct copies of such testimony and exhibits before the District Court, subject to correction of such copies of exhibits on comparison with originals thereof, should error appear.

"7. That if called and sworn to testify as witnesses herein, the following individuals,

L. C. Case	W. A. Hower
S. C. Kiser	R. S. Knappen
Harry F. Wright	R. L. Wright

who gave testimony in the aforesaid case of the Dow Chemical Company vs. Williams Brothers Well Treating Corporation, either on examination in open court or by deposition taken out of court, each would testify to the same facts as they testified to in the said former cause, subject to correction by any additional testimony of any of said individuals taken on behalf of either party hereto.

"8. That insofar as the same may be relevant to any issue herein, either party hereto may offer as evidence in this cause, any portion of the fact testimony of the above identified witnesses named in paragraph 7 hereof, or any portion or portions of any exhibit offered in the aforesaid Williams Brothers case, with the same force and effect as though such testimony had been taken or exhibits had been offered herein, subject to the right of the opposing party to object to any such offer on any ground that might be urged against it herein, if said witnesses had been sworn and examined, or such exhibit had been offered in this cause, whether or not such testimony or exhibit was objected to at the time it was taken or offered in said former cause."

NARRATIVE STATEMENT OF TESTIMONY AND PROCEEDINGS IN DISTRICT COURT

Following is a statement of the testimony and proceedings in the District Court, portions of which are in narrative form and other portions in question and answer form.

The following exhibits were marked and offered:

Copy of Grebe-Sanford Patent 1,877,504 as PX-1.

Copy of Grebe Patent 1,916,122 as PX-2.

Copy of Grebe-Stoesser Patent 1,998,756 as PX-3.

Copy of Chamberlain Patent 2,024,718 as PX-4.

Copy of Gravell Patent 1,678,775 as DX-5.

JAMES O. LEWIS,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I live in Houston, Texas, and am a consulting petroleum engineer. I got my technical training at the University of Stanford where I graduated as a geologist, prepared for petroleum geology. After graduation I spent two years with the Associated Oil Company in California as a field geologist, and after that I spent three years employed by

Harry R. Johnson of Los Angeles and Robert B. Moran then of San Francisco. My work was partly field geology, concerned with oil, except for one special job of a few months, and also some engineering problems in the production and valuation of oil, and the drainage of oil underground.

I then went with the United States Bureau of Mines in the fall of 1914, and was with them for six years.

My first position was that of oil and gas inspector, doing joint investigation work for the United States Bureau of Mines, and the Indian agency of Muskogee, Oklahoma. I worked jointly with the Indian office and the United States Bureau of Mines investigating the causes and remedies for the waste of oil and gas which were then taking place in Oklahoma. I was in that work for one year, and I was then employed by the Bureau of Mines directly for two years in investigative work, mainly concerned with methods for increasing the recovery of oil; methods for estimating the future production of oil and gas, and other methods for conserving oil and gas. During that time I wrote three technical bulletins and papers for the Bureau of Mines.

In 1918 I was placed in charge of the Bureau of Mines Petroleum Experimental Station at Bartlesville, Oklahoma. The station was just being founded. It was the first petroleum station of the Bureau of Mines. Also during that year we had outside work—I mean in addition to the organization of the station, in helium problems, which were then active, working out methods for the Bureau of Internal Revenue, for estimating the reserves of oil and gas, to be used in connection with depletion allowance in income taxes, and other activities in Oklahoma, and elsewhere in the United States dealing with conservation.

During 1919 and 1920 I was chief petroleum technologist of the Bureau of Mines, that is, I was in charge of all petroleum work of the Bureau of Mines during those two years, and was located in Washington, D. C. I left the Bureau of Mines in 1920, and went to Marietta, Ohio, and became a member of the firm of Smith & Dunn. The firm

of Smith & Dunn had a patented process for increasing the recovery of oil by injecting air or gas into depleted oil fields.

In the fall of 1920 I moved to Tulsa, Oklahoma, with Mr. Dunn, and we formed the firm of Dunn & Lewis, which was in business together until about a year ago. Mr. Dunn was the inventor of this process of increasing the recovery of oil, also other processes for cleaning out wells, and helping recovery of oil and gas. Our business there was a general petroleum engineering business but specializing in methods for recovering oil and gas. We had a number of properties which we took over, some under management, some under ownership, to which we applied this process of Mr. Dunn's and other processes. We also had consulting work from larger companies, advising on various matters, namely, South Penn, Central, New Jersey, Tidewater, Petroleum Gas Company, and some other gas companies. During these years I have done a great deal of consulting work on valuation, estimations of oil and gas and various problems relating to the production and recovery of oil and gas. Mostly my work has been on the conditions which exist underground, and the methods for bettering the recovery of oil and gas therefrom.

About a year ago, I dissolved partnership with Mr. Dunn and have been located in Houston, Texas, as a consulting engineer in such problems. At present I am engaged in a joint problem for a group of companies in California, one of the largest fields there—the Kettleman North Dome Field—working out problems connected with what is known as the cycling of gas from the very deep sand which should be used by these joint operations. These companies include most of the larger operating companies in California. I also have similar problems on increasing the recovery of oil in some properties of an English company in Trinidad which company happens to be the largest producer of oil of any British-owned colony.

Q. Now, I wish you would tell the court, please, what were the actual conditions, we will say, before acidizing

became popular, as to the percentage of the oil in the ground which was actually gotten out. Tell them both as to limestone and sandstone. A. It has always been rather a difficult question to estimate how much oil actually is in the ground, and hard to give general answers in magnitude and figures. Also, there have been changes in the character of fields which have been found at different times and in the methods of producing that oil and gas. In the earlier part of the industry most of the oil was produced from what is known as tight sands—they call them sand but really they are sandstones, originally laid down as loose sands but in the course of geological changes have been cemented and the permeability had become quite low. The oil and gas found in them was quite difficult to obtain. While that character of field was being produced, the recovery was obviously quite low. In 1917 I estimated the average recovery was between 10% and 20%. That is, from 80% to 90% of the oil was being left underground. That was probably a little low. Probably they were getting a little more than that, as we since have found out. It wasn't very far from the real order of magnitude. Since that time the character of fields has been different. We have been finding more deep fields, more oil has come out from sands, more permeable, and have made advancements in recovery. So the efficiency of recovery is better, considerably. Probably at the present time the recovery is of the order around 40%.

Now, as to the limestones, there is much greater variability in the question of limestones, and consequently the percentage of extractable oil—probably on the average, the percentage of extractable oil is somewhat higher in limestones than it has been in sandstones. That is, instead of it being of the order 20% in the tight sands, so-called in limestone, it is more likely to be 30%, possibly a little greater. That was up prior to the extensive use of acid.

Q. Now, how long has it been since this increasing of the production of wells was recognized as a real problem to be met by the industry? A. Well, it was almost recog-

nized from the beginning to some extent. That is, the first producers found that the wells would come in in large volumes, comparatively large volumes, and then quickly the amount of oil which the well would produce would shrink, so they were almost immediately confronted with the fact of a diminished return following the completion of the well, and became interested in methods which would tend to increase the daily production.

They did not so quickly become conscious of the fact that after the well had ceased producing, they had not exhausted all the oil, but it was not many years before they commenced to see that they were not getting all the oil, though it took quite a long while for them to get a means of estimating quantitatively how much that was. They knew they were losing some of the oil, and it must be a considerable quantity. The original first Drake well, the first petroleum well in this country, was in 1859.

Q. And how long was it after that before they had some record evidence of efforts to increase the productivity of the wells? A. Well, from the standpoint of merely increasing the daily production of wells, with no respect to whether or not the ultimate production was increased, there are records almost immediately of going in and cleaning out wells. They recognized that the formations would cave off the walls of the hole and fill up the hole. They would go in and clean that out.

Also they had devices for lifting the oil by various pumping means. Gas lifts were first applied very early in the industry, at least, tried out, and as soon as a well ceased to flow under its natural pressure, there were many expediencies applied to increase its daily production.

Then, in 1865, the first method which went further than that, which went more than merely cleaning out the hole itself and bettering the lifting means, was applied by Colonel Roberts, who was the colonel in the U. S. Army during the Civil War who invented the torpedo, as he called it. That is, his method was to put in a charge of nitroglycerine into the well, explode it there, which would enlarge the hole and crack the formations back from the hole some distance, just

how far he did not know, and also tend to clean off the walls of the hole of obstructing materials.

Mr. Lyon:

Your Honor please, it seems to me that from the witness' last statement, something that happened in the Civil War, judging by the fact he said he was a graduate of Stamford University, and Stamford was not founded until the 90's, this witness is not testifying to anything of his own knowledge.

The Court:

I take it this is the recorded history, like who discovered the steamboat.

Mr. Lyon:

It seems to me this is not the proper way to prove it; to prove the history, I mean, by an oral witness.

The Court:

Well, if it is history, it cannot affect the decision of the lawsuit really. It is just background, and I don't want him to use up very much of my time or their money in order to prove this. I take it that if he isn't corrected by some of the people connected with your side he is correct about it. I take this as background and history of an art that goes way back beyond anything I will use in deciding the lawsuit, and yet it is interesting.

Mr. Wiles:

Of course, we want to show that this has been a problem ever since the industry started.

The Court:

I will let him go ahead, and he will come down to something more recent.

By Mr. Wiles, continuing:

Q. This process that you have just mentioned as shooting wells, that continued to a considerable extent up to rather recent times, did it not? A. Yes, it has continued right up to the present time, and is still in use. Shooting is not effective in all formations, either in all sandstones or all limestones, but it has favorably affected production, above the rate, and the ultimate recovery in many limestone fields.

Q. Is there a rather localized effect, close to the well, or can it be extended for a considerable distance? A. We know from measurements of the size of the hole after shooting that it has not enlarged the hole very greatly, that is where the hole was originally six to eight inches in diameter, it may enlarge it to some twelve inches, something like twelve inches, and occasionally eighteen inches, but it also cracks the rock, but how far it cracks it I do not know, and I have never heard any figures which would prove how far back it cracks it.

The Court:

Is there anything about whether or not the fact it might make a well to it,—like where you applied it to the stump out here or a hole in the ground? It doesn't take it with this rock, as I understand; it tends to split it rather than throw pieces back? A. It can't throw the rock back because there is no place for it to go, and it can't blow up because you have the formations holding it down, unless you put in an overcharge, and if you put in an overcharge, of course, it might do damage to the top of the well if the well was shallow. The figures I gave in 1917 were made in view of shooting the wells and the processes of increasing recovery except the use of injected air or gas, and except the use of flooding. In other words, they were for methods used prior to those two processes.

The Court:

Shooting them would increase it, it helped? A. Oh, yes, very greatly.

The Court:

What other method did you say besides the shooting of them? A. They used various methods for cleaning out the hole itself, and at a later date in 1869 they applied what is known, what they then called a gas pump which was a vacuum pump. And, the principle on which they operated was to remove the atmospheric pressure and permit the gases in the rock to expand an additional few pounds.

The Court:

You mean pump the air out and make a vacuum? A. There wasn't any here in the underground, but they made the casing head tight, and connected the pipe to the casing head and applied this suction pump to it. The vacuum has been used up to the present time.

The Court:

You made your vacuum above. Wouldn't that tend to make that oil come up? A. It would tend to make the oil flow more freely and expand the gas which was in the rock. You see, your oil is flowed from the pores of your producing formation in the wells.

The Court (Interposing):

Held under pressure? A. Originally, your oil with the gas in solution is under considerable pressure, and that gas expands and pushes the oil with it to the well from which it is lifted to the surface by either natural flow or various mechanical means. In time your natural gas forces become depleted and become ineffective until finally if you don't do something to replace these natural forces you wouldn't have enough force to force your remaining oil to the well. At that stage these old operators would go and put on their vacuum pumps, or gas pumps they then called them, and by removing atmospheric pressure it was the same as if they put into the sand another twelve or thirteen pounds of pressure, because it allowed the gas to expand against that much less pressure, and your gas in expanding had atmospheric pressure, which is about 14.7 pounds at sea level, and by using a gas pump you could remove that pressure from it and allow the gas to expand that additional amount.

Mr. Wiles:

Q. To get some idea of how important this vacuum is in per cent, proportion, what is the underground pressure likely to be like, say, at several thousand feet? A. The underground pressure, that is the original underground pressure has an extremely wide range. It is usually in approximate proportion to the depth, and usually it is

about 43 pounds pressure for each 100 feet of depth. That is an approximation which isn't true, but is generally true, so that the first wells, which were shallow, had original pressures of maybe less than one hundred pounds. In recent years where they have been drilling to great depths wells of ten thousand feet or more they have pressures of five or even six thousand, even seven thousand pounds initial pressure. So that pressure varies with those great ranges in accordance with the depth more than any other factor.

Q. In view of those figures, the 15 pounds difference that you can make with a vacuum would be rather insignificant, would it not? A. The amount of push which the vacuum or gas pump would make was not large and was negligible in the deeper sands. In some of the shallower sands it was rather important, but it could not be a highly effective process.

Q. Now, there is a process known as re-pressuring, is there not? A. Yes. The word "re-pressuring," I might say, is used in a good many different senses, but in the sense I believe you mean it is the injection of either compressed air or compressed gas into a depleted field. That is, instead of what you might say putting a pull on the sand by a gas or vacuum pump you can put a push on it by taking air or gas and compressing it in a compressor, and injecting it into one well and allowing it to flow through the sand into producing wells around it. And, of course, the pressure which you can generate in that manner is unlimited, whereas the additional pressure which you release from the sand by a vacuum pump was distinctly limited.

The Court:

I suppose you have tried to apply your air to some low place in the pool and get it out at a higher place? A. There have been various theories and the theories have been applied very largely in accordance with local conditions. In some pools it seems to be better to distribute your output and input wells, producing wells as they call

them, in some structure which seems to be best to put all your gas in the high part, and force your oil down so that the oil will flow with gravity in addition to the aid of your pressure. In other cases they have them put it in at the edge of the pool and forced it up. Generally the best practice, at least a practice which the engineers seem to agree upon, is to put it in the high part of the structure if there is a pronounced depth to the sands.

In limestone formations the repressuring systems have not been markedly successful. It has been tried in a good many cases, and it is very seldom successful. The reason seems to be that the pores in your limestones are of a different origin, and have a different nature than sands, and your air or gas will, of course, take the lines of least resistance, and usually in limestone there are channels of resistance which are so much less than the body of the limestone that your air and gas would pass through, doing very little good.

For example, in the Trenton pool, an application I know of, they injected the air into the formation, and instead of that air showing itself about the nearest wells, it followed a line across the field and appeared in wells a distance of a mile away, apparently having followed a fracture zone. That seems to be the most logical explanation. The exact conditions we were unable to get any proof of.

Q. There are methods also where you add water, are there not? A. Yes, instead of putting in a gas, you can put in a liquid, and practically the only liquid which would be commercially feasible was water. I do not know of any case where it has been very effective.

Also, prior to 1931 we used various reamers which would go into the ground and enlarge the drill hole from its six or eight inches to so much as three feet in diameter, that is, ream it out mechanically. That was used to a limited extent, and did some good. It increased production some, but not to a highly important degree.

There were also methods for removing the paraffin which would accumulate in the pores; that is, as the well

gets old, certain oils have paraffin waxes in them, which would separate out; and this paraffin would accumulate in the pores of the sands immediately around the hole and clog it up. There are various treatments for that, such as steaming it out, circulating hot oil, putting in chemicals, electrical heaters, which would remove the obstruction. That also applied to old holes where mineral matter had been deposited in the pores of the sands and clogged it up. To remove that they have put in light shots, which would crack it off.

Q. As far as wells in limestone are concerned, aside from the shooting process which came in, as you said, in 1865, was there any serious method developed that went into practical use to any extent? A. Well, up to acidizing, I don't recollect any methods which came into general use and were of any importance.

Q. When did proration come in? A. The first proration was generally effected about 1926 in Oklahoma and created a special reason for obtaining maximum daily production from a well. The formulas for prorating the production of wells were based upon what they call the potential of the well, either wholly or largely. That is, if the well had a capacity to produce, say, one thousand barrels if it were allowed to produce its full quantity, it would be given a higher allowable than a well which, say, could only produce five hundred barrels a day. So the incentive on the part of the operator was to put his wells in condition so that they would make the best showing when these potential tests were made.

Q. Now during this same time, do you know of processes for increasing the production of wells which were tried experimentally and abandoned? A. Oh, I used to hear of various methods and ideas of increasing recovery. Of course, it is my business—

Mr. Lyon (interposing):

Your Honor please, I don't think we ought, if this evidence is going to be used, to receive evidence about what this witness heard, which he characterized as abandoned or experimental.

The Court:

If it is something you dispute, I would adhere to that, I think.

Q. Name the methods you know about or which became known in the industry so that, as an expert, you would know about it? A. One of them I know of personally was the idea of heating up the rock by either forcing in steam through the producing formation or hot water or some other fluid which would be a conveyor of heat into the rock, the theory being that you thus reduce the viscosity of oil and also you generate gases from the gasoline which was a part of the oil in the rock. The idea was to pump the hot water in through the wells right into the formation.

The Court:

It would get cold before it could get down there. A. That is exactly what happened. All of those methods, however, were tried, and personally I made many, many calculations on them. They all failed because the mass of heat in the rock itself was so great that it was not feasible. One plant they tried it and got a good increase, but they found that putting steam into the rock, they found it took all the additional oil they recovered and all they produced before to raise steam to heat up the rock.

The Court:

What is the temperature down there a couple of miles? A. When you get down a couple of miles it is likely to be around 250 degrees Fahrenheit. One hundred feet down it will generally be the average surface temperature, which in this (Michigan) climate, if you average the year round temperature is about 45. That is my guess.

The Court:

You get down a mile and it would be how much? A. The general rule is that your temperature increases one degree Fahrenheit for every 70 feet of depth, and you start at the surface. That is, your average yearly atmospheric temperature becomes the temperature of the rock at about 50 to 100 feet below the ground, and your heat gradient, as they call it, begins from that point. Down south in

Texas the average surface temperature is around 75 and up here I suppose it is about 45, so you start with a temperature which is lower, but your increase is about the same.
The Court:

One degree for each seventy feet? A. About one degree for each seventy feet of depth. You have so much pressure your water couldn't boil. You get away above 212 degrees, only your boiling point has the factors of temperature and pressure.
The Court:

You mean you can't get steam down in there? Can you? A. In the shallow oil well they can insulate the tubing carefully, and get down there and insulate the rock. What happens is the steam gets in the rock, then it condenses, then it cools off, so all you are doing is increasing the cycle of water. You start with the steam at the surface of the earth and force it right down through the tubing of the well into the sand. It never has been tried on deep wells—only shallow wells. It hasn't been successful. It isn't practical.

Another method, to continue my answer to your question, is to mine the oil. That is, sink shafts down to the sand and drive tunnels along the sand and let the oil drain out. I have seen some of those shafts and tunnels. It is feasible at a price but it costs so much that it wouldn't be commercially feasible at prices we have had in recent years.
The Court:

I don't get the idea of how you would tunnel it. A. You would tunnel it as you would in a coal mine—sink a shaft and drive drifts. It has been done for years.
The Court:

Drive it out sideways? A. Drive it out sideways. There is considerable danger in it but they have means of overcoming that danger.
The Court:

How deep do they drive? A. They can go to as great a depth as they could in ordinary mining operations.

The Court:

Well, what is that? A. I don't know as there is any limit. The only limit is the temperatures they reach, and the cost. They have mines in this state over 6000 feet deep. This mining of oil was actually carried on commercially in France and Germany, where the price of oil was greater. In this country it is not feasible at present prices—purely a matter of cost.

The Court:

Then it goes out laterally? A. Then it goes out laterally, and they elevate it.

By Mr. Wiles:

Q. Now, taking the time from, oh say, 1910 or so, when the automobile began to greatly increase gasoline demand, what was the belief of the industry and of the government as to the future of the oil supply? A. The government and the industry generally went through a period of apprehensive shortage that commenced during the World War and continued for some years thereafter. That is, at that time they became conscious of the great need for oil and also of the fact that our oil fields were limited and sooner or later would exhaust. At that time there was a feeling that the period of exhaustion was quite close, was quite imminent. It wasn't until the late twenties that that apprehension was relieved, and they came to the conclusion generally we had more oil than we had originally thought.

Q. You have reserves in sight for many more years now than you had, say, in 1919? A. Yes, I believe we have.

Mr. Wiles:

I have here a Bureau of Mines Bulletin No. 177, published in 1919, and want to quote just one sentence, and I ask you whether this is a fair sfatement of the general attitude of the trade and government?

"At present the country is facing a serious shortage of petroleum. By way of preparing for the best way to meet this emergency, the Bureau of Mines has been carrying on technical investigations in the petroleum industry for several years." A. I believe that represents the majority of the opinion at the time.

Q. I hand you Bulletin 148 of the Bureau published in 1917 (PX-7). Is that your work? A. Yes, I wrote this while I was with the Bureau of Mines.

Mr. Wiles (reading from bulletin at page 7):

"In its efforts to reduce waste, and increase efficiency in oil production, the Bureau of Mines is investigating methods of increasing the recovery from the underground sources of supply, which are the foundation of the petroleum industry and the many allied industries wholly or partly dependent on it. In the face of a demand that is increasing faster than the production and that, in the consensus of opinions of well-informed authorities, is soon likely to outstrip the productive capacity, it is well to consider whether it is not possible to extract more oil from the known sources of supply. It is universally acknowledged that by the usual production methods much oil is left underground, the general opinion being that at least 50 per cent of the oil in a field remains unrecovered when the field is abandoned as exhausted. From the writer's own investigations he believes the average recovery is even less, and if any considerable portion of this oil being left underground could be made available it would have a tremendously favorable influence on the petroleum industry and all the industries dependent on it.

"In this publication are considered the principles involved in increasing recovery and methods of extracting more oil from the oil-bearing formations than by the usual ways of producing. These methods are: The use of gas or vacuum pumps, forcing compressed air or gas through the oil-bearing formations, displacing the oil by water, and better utilization of the natural pressures in the oil-bearing formations. Especial attention is being given to a process —commonly known as the Smith-Dunn—for forcing compressed air through oil-bearing formations because it is believed to hold most promise for the future.

* * * * *

"That much of the oil in a field is never recovered is well known, but how large a proportion is left underground

and the possibility of increasing the recovery cannot be fully realized until one clearly understands that the exhaustion of an oil well is due more to the exhaustion of the natural gas, which is the principal agent in driving the oil into the well, than to the exhaustion of the oil itself.

"Facts presented in this bulletin go to show that the capacities of the oil sands in the various fields of the United States are five to ten times greater than the quantities of oil commonly extracted from them. If it could be fully established, as seems most probable, that the pores of the oil-bearing sands were completely filled with oil at the time the fields were first developed, then 80 to 90% of the oil is left underground when the wells are abandoned. Although the evidence at hand does not permit positive statements that this proportion is being left underground, there is abundant evidence that much oil capable of being recovered remains in the sands. Complete extraction is not to be hoped for, yet there is no reason to conclude that the maximum possible recovery has been reached when the natural forces have been exhausted, and, furthermore, it has been demonstrated that it is practicable to get more oil from the sands by the processes described in this report."

(The bulletin was offered and received as PX-7.)

The Court:

Is there any reference in this book to the acid?

Mr. Wiles:

No. This was published in 1917.

The Court:

Didn't you know about the Frasch patent? A. No, I hadn't heard of it. During all this period up to, say, 1932 acidizing of oil wells was not one of the things that was known and used generally all through the trade.

By Mr. Wiles:

Q. When was it that you first heard of acidizing as a practical proposition? A. Well, I had heard of it—in fact, witnessed a test as early as 1918 on oil producing sandstone to knock off the crust, and again in 1922, something like that, for the same purpose. The first I heard

of acidizing on limestone formations was,—it must have been about 1932 or 1933. I can't remember the exact date. I first learned about the Frasch patent in connection with this case, within the last month.

Q. Within your experience now, how was acidizing received about when it was brought out in 1932? A. Well, it was received unusually rapidly for a new art in the industry. My experience at the Bureau of Mines where our principal function was to find and apply and introduce new methods led us to believe there was usually from five to ten years' inertia to overcome in introducing a new idea to the industry, and this was adopted much quicker than any other new idea within my experience.

Q. How soon was it,—how extensively did it become used in wells in limestone? A. Well, within a very,—only a matter of months, reports came in from almost every part of the United States where they had limestone fields. I think within two years I don't believe there was an area in which limestone production was important that I hadn't had reports that it had been used there.

The Court:

Well, we generally find seventeen years after a patent is granted the public gets the thing. What explanation have you got that that patent of 1896 didn't grow any fruit? Aren't you satisfied you could use, without any inhibitor, an acid to better advantage than you could blast or steam and these other things you have been telling me about? A. Well, it has been proved by experience that acidation is better than those other processes.

The Court:

Even if you didn't have the inhibitor? A. Well, I couldn't say as to that. Of course, the only thing I can say is that probably the early users of acid must have encountered so much trouble from it that they were discouraged, and these methods which were all coating pipe would not be such as would be practical in oil wells.

The Court:

They couldn't have tried very hard or encountered

much difficulty or the other hand of the government would have found out about it. Here is the patent hand of the government. The government has so many hands, they don't find what they have got in their pockets, but here is the Patent Office down there with this patent right on file in there, and you are right over in another branch of the government in the same city telling all these ways, and there is a better way than any of those you were describing right there, even if you did not have an inhibitor, I take it. Maybe I am wrong about it. A. I couldn't say as to that, whether the raw acid might do it or not.

The Court:

Have you got any of that history about that? Did you ever, you think, run into difficulty? I take it you are just theorizing about it? A. That is purely surmise. I have no history.

The Court:

Isn't there any available history about what that chap did with his patent, or what they did out in the oil fields? A. If there is I don't know about it. I haven't made any search for it.

The Court:

Do you know, was he an oil man? A. One of them, in fact both of them, were in the oil business.

I recall this Frasch patent. There is a possibility that the acid might eat around the packer.

By Mr. Wiles:

Now, my view about this is this: Frasch puts in his patent, and he was a great man and everybody looked up to him with the greatest respect, and he says, "You can't put raw acid down there or you will spoil your pipe. Therefore, you must pull your pipe, put down a rubber covered pipe, and then introduce it, and then take out the rubber covered pipe and put down your pump pipe again." Now, considering the expense of bringing this special pipe in adequate quantity, and the assembling and disassembling you have to go through, do you think such a process would be acceptable to the trade at any time?

Mr. Lyon:

I object to that as too speculative, Your Honor. The witness hasn't qualified.

The Court:

Overruled. I have invited the question, I guess. I will let him develop it. A. I don't know as to what they knew back there in '96 or what they had, but I think it would be very difficult even under present knowledge to work out a system which would fully protect the pipe in that manner and prevent corrosion.

The Court:

How much is a mile of pipe worth? A. Well, it depends on the size. Tubing, ordinary two inch tubing generally costs about 25 to 35 cents a foot, according to the quality and weight of it. A mile of pipe would cost say $1500, I should say off-hand.

The Court:

How long will it take that acid to eat through. A. I was going to add, if they keep that acid in any length of time it would be very difficult to get any protective which could be taken apart and put together again that wouldn't allow the acid at least to get into the seams.

The Court:

If you don't put the protective in there, how long would it take to eat through that? A. Oh, I don't know.

The Court:

Give me some idea? A. Well, I haven't gone into that.

The Court:

Days or weeks or hours or years or what? A. Well, I would say—I would have to more or less guess at it—I would say twenty-four hours, if the acid was left in the tubing, it would very likely eat through the walls.

The Court:

There may be some chap who had a poor well, a good sport like most of them have to be to put money down in the ground, who tried it out to see what would happen. A. They may have tried it. I don't know.

By Mr. Wiles:

Q. Now, can you tell us approximately the proportion of the oil production that comes out of limestone? A. Well, that is very difficult to get any precise estimates on and I haven't a precise estimate. All I can give you is the order of magnitude, and I would say it is about twenty-five per cent of the present daily production which is from limestone formations.

The Court:

Is this acid any good in sandstone? A. It has had, under special conditions, beneficial effects in some sandstone, where the sand contains a certain amount of carbonates, and in such case the acid may eat out this carbonate content and enlarge the pores and in that way increase the permeation.

The Court:

Has there been any other kind of acid they use for different kinds? A. Yes, they have other acids. They have proposed to use hydrofluoric acid which would eat the sand itself, but so far as I know that has not been satisfactory. It has not been practical. And they have mud acids which will eat a certain content of the mud which sometimes clogs the pores of the hole and which seems to be beneficial quite often.

By Mr. Wiles:

Q. Can you give us a rough idea of the price range of mid-continent crude for the period preceding 1932? Start with the Cushing pool in 1915 when prices were way down. A. I couldn't give you the exact figures. About all I could give would be some approximation. Prior to the Cushing pool the price ranged from a low of about 50 cents up to a little over $1.00. During the Cushing pool the price went down to a point where they were not quoted. Oil was sold at the Cushing pool at a net of 10 cents a barrel. That was sold in the tank, and when you took away the tank cost, the oil itself sold for about 10 cents.

Then in 1916 it commenced to go up again, and about 1917 it reached over $1.00. During the World War it was

artificially held down to I think $2.25. Then after the War it reached an all time high of $3.50 in 1920, I believe.

In 1921 the oil price took a plunge along with other commodity prices and it went down to $1.00 in the latter part of 1921 or 1922. Then it wavered back and forth reaching a high of about $2.00 and went down again about 1925, and in 1926 36-gravity oil went up to $1.86, I believe.

From 1926 to 1930 most of the time it was between $1.00 and $1.50 and it averaged about $1.25. In the latter part of 1929 or 1930 it started to go down again, and in 1931, on account of the flood of oil from the East Texas pool and also the depression, it went very low. In 1932, due to better control of production it went up again. In 1933 proration broke down and it went very low. Since that time, it has averaged about $1.00 or $1.10.

CROSS EXAMINATION

I was with the Bureau of Mines from the fall of 1914 to the fall of 1920, six years altogether. As to whether or not during that period there was any knowledge in the Bureau of Mines of the use of hydrochloric acid in an oil well to react on the formation, all I can say is that I do not remember of its having been brought to my attention. However, there could have been knowledge of it on the part of some of the individuals in the organization. I know a man by the name of Rollin Van Auken Mills. He was connected with the Bureau of Mines during the last two or three years that I was there. He was a petroleum engineer, and his field of work was research on the treatment of wells and oil recovery. I think his principal problem was on the paraffin troubles. He worked under my general direction.

I have seen a bulletin, serial number 2550, dated December, 1923, entitled "Reports of Investigations, Department of the Interior, Bureau of Mines, Subject, The Paraffin Problem In Oil Wells," by R. Van A. Mills. It was prepared after I left the Bureau of Mines, but I read it

afterwards, and I have read it recently. The work covered by it was started before I left the Bureau of Mines, under my general direction.

By Mr. Lyon:

Q. Well, now, this bulletin on page 9 has a paragraph entitled "Hydrochloric acid," and the text starts, "The Bureau of Mines has experimented with the use of hydrochloric acid," and so forth. Do you have any knowledge of the work that is referred to there? A. Well, I knew some of the work that he did before I left the Bureau of Mines; I know he had tried various chemicals in wells.

With reference to the patent issued to Mr. Mills No. 1,421,706, dated July 4, 1922, on an application filed October 15, 1918, I knew that he was filing for several patents, but I did not know just what they covered. He was connected with the Bureau of Mines on October 15, 1918.

Q. (By Mr. Lyon) This patent or patent application was dedicated to the public by Mr. Mills under the Act of March 3, 1883, as noted on the patent. Was that at your direction as head of the department? A. No, it wouldn't be under my direction, because I wouldn't have anything to do with the control of policies which refer to patents. I believe it was the practice of the members of the staff of the Bureau of Mines, while I was in charge, in filing patent applications to dedicate their use to the public under the Act of March 3, 1883.

Q. Now, this patent, on page 2, line 18, refers to the acid treatment of wells. Do you know what that refers to? A. I wouldn't know without reading the patent itself to see. There are two ways in which acid has been used in wells. One was the one I described yesterday as having witnessed in 1918 where it was used to remove the incrustations of mineral matter and mineral matter which had been deposited in the pores of sand. The other is to be used only in limestone wells, and I don't know what that refers to.

Q. Now, did you have knowledge of both of those methods while you were with the Bureau of Mines? A. The

only one that came to my attention while I was with the Bureau of Mines was the one for removing mineral incrustations in the sandstone wells.

Q. What is the difference in the action of the hydrochloric acid after you pump it down the well and force it into the formation whether the formation is sandstone or limestone? A. Well, only the chemical action depends on the materials in the well on which the acid acts. If there is any lime in the sandstone well, the reactions would be the same as if it was only limestone formation. That is, for that part of the reaction. Your reaction may also take place with other mineral matters in the sandstone well, which possibly might not be present in a limestone well.

Q. Then is there any sure distinction between these two methods that you have referred to or do they overlap and intermingle? A. I wouldn't say—of course, it is a matter of the structure of the reservoir rock. In one case the whole reservoir rock is soluble in acid, or mostly soluble in acid, and in the other you have a structure of insoluble material with a filling of acid soluble material or at least partly acid soluble material.

Q. Well, in either case the method is the same in the sense that you perform the same physical operations in introducing acid into the well and causing it to penetrate the formation, and the only difference is that the effect of the acid will vary with different formations; is that correct? A. Well, speaking broadly, I think that is correct.

Q. Now, as I understand you, even today the results of acidizing a well are not uniform. Some wells you obtain beneficial results and others you do not, is that correct? A. That is the general report, yes.

Q. And particularly true on old wells, is it not? In some old wells you can increase the production by acidizing them; others you cannot? A. It is variable, yes.

Q. It is also true on new wells. In other words, you may acidize the new well and obtain no beneficial results from the operation, is that not correct? A. That is true, yes.

The bulletin, Serial No. 2550, above referred to, was thereupon marked and offered as DX-8.

By Mr. Lyon:

Q. In your testimony, Mr. Lewis, yesterday you were asked: "Q. When was it that you first heard of acidizing as a practical proposition? A. Well, I had heard of it, in fact witnessed a test as early as 1918 on oil producing sandstone to knock off the crust, and again in 1922, something like that, for the same purpose. The first I heard of acidizing a limestone formation was, it must have been about 1932 or 1933, I cannot remember the exact date." Was this work by Mr. Mills which we have been discussing the occasion of your hearing of the acidizing in 1922? Is that the work that you referred to? A. That is what I had in mind, yes.

Q. That was the work that you referred to in your testimony of yesterday? A. Yes.

Q. It would appear from your testimony that you had had some earlier knowledge of acidizing, in 1918, is that correct? A. Yes, sir.

Q. Who did that work? A. While I was stationed at Bartlesville, one of the oil operators asked me to go out there and witness a test of a well by a couple of men, I believe they were from Kansas City. I went out there, and they poured some acid down in the well. I don't know whether it was inhibited, or not, but it made quite a commotion.

Q. Do you know what kind of acid it was? A. It was hydrochloric, I believe.

Q. What makes you believe it was hydrochloric acid? A. Well, just from the reaction, but I do not know positively. I did not pay much attention to it because it was just an experiment, and I was very busy with other things at the time. But I afterwards made inquiries to find out what had happened to the well.

Q. When, how long afterwards? A. A few weeks afterwards. I found out, or, I was told that they had treated a couple more wells, but the effects had not been worth while, and I heard no more about it.

Q. That could be true today, the same thing could happen today with the present methods of acidizing, using the present materials, could it not? A. You mean that no worthwhile results would be obtained?

Q. You could go out to some wells and give them a treatment, treat them, acidize them by these modern materials, and get no favorable results? A. That sometimes happens, yes.

Q. That is all you know about that operation in 1918? A. That is all I remember of. I do not believe there was any reports came to my attention after that.

Q. You say the results were not worthwhile. You mean by that that the action of the acid on the formation did not accomplish any useful or practical purpose, is that what you mean? A. The owner of the wells reported to me that the results were not worth while, meaning that they had not increased production enough to make it worth his while.

Q. You did not hear anything about any difficulty in connection with corroding the pipe, did you? A. Nothing came to my attention.

Q. How much oil, and what percentage of the oil in the ground is supposed to be recovered today, as compared to 1925? A. By the use of better methods, and because the fields naturally are more conducive to high recoveries, recoveries are much higher today than they were at the time that I wrote that bulletin. (PX-7.) I would say as an approximation that the average recovery was of the order of 40 per cent of the oil originally in the ground.

Q. Over what period of time? A. That is to exhaustion, by present methods which are in use. When I say that they are recovering 40 per cent from the ground, I mean within the economical life of the wells. For instance, the East Texas field was discovered in the latter part of 1930 and is still producing. There are various estimates as to the percentage of the oil in that field that has been produced up to date. It is about 30 to 35 per cent of its ultimate. That is due, in part at least, to the fact that the

wells are largely shut in, and not allowed to flow to their capacity, or to be pumped to their capacity. That is, they have gotten about a third of the oil out that I think they are going to get out. As to how much of all the oil that is in the ground they expect to get out, the East Texas field happens to be an unusually favorable field for high recovery, and it has been operated in such a manner that this manner of operation is favorable to high recovery, and probably they will get over 50 per cent of the original contents. I would say that this Texas field is a good example of the fact that I called attention to in my testimony yesterday of the obtaining of a bigger percentage of the oil in the ground now than was customary fifteen or twenty years ago. I have not heard of acidizing being employed in that field to any extent. I never heard of any acidizing there.

I know of the Signal Hill field in California. It has been a very remarkable field, an outstanding field in the oil industry in this country. They started producing in that field about 1920. That field covers the top, or mostly the top of one hill. My recollection is that about 600,000,000 barrels of oil has been produced from that one hill or one field. I don't know what proportion of the oil that is supposed to be in that field has been actually produced and gotten out of the ground. I have heard that it is cited usually as an example of the best recovery of oil that has been accomplished up to date in any given field. That it is the best recovery per acre, but as to the percentage of recovery I don't know.

My calculation of comparison in the amount of oil produced today as compared with twenty years ago, in comparison with what is in the ground was a broad estimate. I didn't go into details. I would not be willing to accept the Signal Hill field as having one of the best records in the oil industry in regard to per cent recovery unless I knew more about it, because they had a tremendous thickness of sand which would have given you that high recovery in barrels, but might have been a low recovery in per-

centage. As to whether the percentage recovery may have been very high, I couldn't say. I have no figures. I never heard of any of the wells on Signal Hill being acidized. It is not the kind of property that acidizing does much good on.

The Court:

The reason for that situation that you have just told us about is because the formation can't be eaten by acid, or what is it? A. Yes, sir. The formation is a sand and not a limestone and that is true, also, of East Texas. Yes.

By Mr. Lyon:

Q. Now, you gave us a figure yesterday to the effect you thought it would take about twenty-four hours for hydrochloric acid to eat through a piece of oil well pipe. You intend it to be understood that that was merely a guess, that you did not have any basis for that figure, isn't that right? A. That is true.

Q. You don't actually know the rate at which hydrochloric acid dissolves or corrodes iron, do you? A. I have looked that up at various times, but I don't remember it right now. I will have to look it up again.

I couldn't say whether, if you fill a pipe with hydrochloric acid, a piece of oil well tubing, there would be enough acid in it to corrode through the pipe before the acid exhausted its power. I understand that in this acidizing, they usually take precautions to see that the acid does not come in contact with the casing.

REDIRECT EXAMINATION

The case I spoke about in Bartlesville, where they put acid down a well, it was a sandstone formation, so that all it could have done would be to wash the surface.

In the Bureau of Mines, the Petroleum Division that I spoke of is subdivided at least so there is a department for refining processes, and one for production processes, and there are several others. The Bureau of Mines studies and reports on refining methods just as fully as it does on producing methods.

These fields Mr. Lyon asked me about as having particularly high production—East Texas and Signal Hill, both are sandstone formations.

The Court:

So far as this acid is concerned, you couldn't use it? A. Not this acid.

The Court:

It likes lime? A. Very fond of lime.

The Court:

And therefore it is useful, as I understand it, you get a sandstone with limestone formation in it, it will break that down and weaken it because it eats out the lime part of it, is that the theory? A. It has had a little success in sands which are cemented by lime.

The Court:

It would eat out the lime but wouldn't touch— A. —touch the sand, but it hasn't been generally successful.

The Court:

Let me find out what you think happens. Now, take the ordinary limestone, is it pretty pure so that it takes in this chemical and forms a new chemical? A. Yes, it forms calcium chloride.

The Court:

Well, would that be a liquid or solid? A. That is soluble in water.

The Court:

And is there water enough down there? Should I have a picture that it is eating this rock and then it is becoming filled with water in there? A. According to the statements made yesterday, they use a 12 to 15% acid—that means 12 or 15% of it is acid and the rest of it is water. So it is a solution of acid.

The Court:

And then they pump that out? A. They pump the spent acid out of the well.

Sometimes these formations we call limestones are dolomites, a mixture of carbonate of lime and carbonate of magnesium. Both of those dissolve in the same solution, except the dolomites dissolve more slowly.

The introductory paragraph of Bulletin 351 of the Bureau by Judge S. Rice, published in 1932, entitled "Mining Petroleum by Underground Methods," which reads—

"The methods of extracting petroleum from sands or sandstones of wells have been studied for years, but while methods have been greatly improved in the last decade the present percentage of extraction of the total amount of oil and sands according to various petroleum authorities is usually only ten to thirty per cent. If stimulative methods are used under favorable conditions the recovery may be greater," represents a generally accepted view as of 1932.

The term "sands" is used very loosely in this business, and is frequently used to cover limestone, or anything else, dolomites, or anything that is an oil-producing formation. It is sometimes used to cover anything that will produce oil, any formation.

JAMES W. REBBECK,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I am employed at the Dow Chemical Company, Midland, Michigan, in the Patent Department, and have been in its employ since March of 1928.

I graduated from the University of British Columbia in 1920 in the department of Chemical Engineering with a

degree of Bachelor of Science. Then I entered the University of Toronto in the fall of 1920 to take some postgraduate work in chemistry there. I was attached to the faculty of the Department of Chemistry of the University of Toronto from 1920 to 1923, and in that interval obtained the degree of Master of Arts. From 1923 to 1926 I was on the faculty of the Department of Chemical Engineering at the University of Toronto. I also engaged in postgraduate work during that time in physical chemistry, colloidal chemistry and organic chemistry, and from the year 1920 to 1927, while at the University of Toronto I conducted a number of researches on the electrolysis of glass and some other subjects. After leaving the University of Toronto I entered the Mellon Institute of Industrial Research at Pittsburgh, Pennsylvania, and from there I went to the Dow Chemical Company as a research chemist.

In the beginning I was hired by Dow to engage in research on industrial chemical problems, particularly in connection with calcium chloride manufacture and uses, chlorine production, bromine production, iodine and other inorganic chemicals; and then I was transferred to the problem of corrosion, scaling, and other problems in connection with the power plant over there in Midland, Michigan; water purification. Then I was transferred to the metallurgical department, and engaged to study the metallurgical problems in connection with magnesium. Then I was transferred to the fabrication department handling the manufacture, casting, forging, rolling, and so forth, of magnesium and its alloys. That is what they call the Dow metal, that being the trade name for a series of magnesium base alloys manufactured by the Dow Chemical Company.

Thereafter I was transferred to the patent department, and began studying the patent art relating to magnesium. From that I entered the patent angle of the business of treating oil wells and gas wells, and related wells. That necessitated studying the patent art relating to those matters. I made a number of compilations of United States patents in that field.

The files of the Dow Chemical Company in that line and in other lines relating to the production of oil are complete, so far as I know, in that special phase of production wherein a well is treated with some material by introducing the same into the well. It includes in connection with that other related topics, such as repressuring, the use of heat in oil wells, chemical and non-chemical solvents. I haven't a complete collection of the publications in that line, but the patent collection, so far as it relates to the use of materials in wells for some purposes is believed to be quite complete.

I have heard most of the testimony of Mr. Lewis regarding various methods which have been tried in this country for increasing the production of oil and can refer to patents illustrative of the various methods to which Mr. Lewis referred. I brought with me a collection of United States patents that represents a selection of a much wider and larger number of patents, and these, I believe, are very typical of the sort of patents in this field. For simplification in considering them I have classified them into six different groups, main groups. The classification that I have adopted is as follows:

First, the use of heat in a well, and I have subdivided that into 3 groups, where the heat is generated in the well, or, 2, generated in the formation, or, 3, where a surface heated heat transfer agent is introduced into the well.

The Court:

What does that middle one mean? A. That is where the heat is produced. Passing an electric current through the rock is an illustration of the middle classification, namely, the generation of heat in the formation.

The second main division is the use of solvents, and these may be subdivided into two classes—first are chemical solvents. For example, hydrochloric acid, which chemically dissolves the rock; and, second, nonchemical solvents such as gasoline and the like, which works like water on sugar.

The third main division is re-pressuring. The fourth,

flooding. The fifth, vacuum. Then the sixth is the catch-all, or a miscellaneous group, such as the use of hammer blows; another is a type where water is flowed toward the well, and, according to the theory of the inventor, the water is supposed to carry oil with it by adhesion. Another example is a patent issued to Van Auken Mills, about whom we heard some testimony; and that has to do with preventing water infiltration into wells, although there is an incidental mention of the use of acid, the purpose not being stated.

I have not included mining operations in any of these classes. As I said before, these are in connection with patents wherein something is introduced into a well. Now, I do have some information about patents on mining. I have here a collection of patents, maybe some twenty-five or thirty of them, more or less on the subject of what might be called oil mining, wherein one carves out the oil bearing earth or rock to recover the oil from the carved-out portion; or produces caves, channels and the like in the oil bearing rock to produce drainage galleries, through which oil may be collected and be brought to the surface of the ground.

Q. Will you proceed with your classification, and call attention to the approximate number of patents in each class, and select one of them as typical, and explain it to the court, please confine your answer to patents issued priod to 1932. A. Under the use of heat, my first classification, Subdivision 1, a typical example is an early patent issued to Edward L. Roberts, patent No. 47,458, dated April 27, 1865. This device is for bringing an explosive charge into the bottom of a well where it can be exploded and shatters the rock. Now, A. E. L. Roberts, I am advised, also obtained a patent on his method in 1866, patent 59,936, copies of which are on order at the patent office, where I would be able to show that he had a patent on a method of increasing the capacity of oil wells, which was based upon the use of a device of this kind, or the shattering of the rock by an explosive.

Another example of a patent in this class, one issued to

Butler G. Noble, No. 105,590, dated July 19, 1870, from which I quote the following: "Many wells after yielding oil in large quantities, gradually diminish in productiveness and ultimately cease to produce in paying quantities. This failure in yield is not always because of exhaustion of supply but results from the clogging up of the seams or natural ducts leading into the well bore by the deposition of paraffin and perhaps other carbonaceous matters." And he proposes to generate heat in the well hole to melt out these deposits, heat being generated by the combustion of slow burning gunpowder or something of that type.

Another example more or less typical in this field is the patent issued to James Dickey, No. 106,793, dated August 30, 1870, for improvement in removing deposits from wells, and his proposal is "introducing the gas to the top of the well and firing it thereat. When the well is cased it immediately ignites the deposit in the interior of the well casing and burns downward consuming as the fire moves downward, and the burning ceases when the paraffin is consumed." That was to take it off of the inside of the tubing. The gas referred to here is something which would support combustion. It isn't the gas from the well. The gas that is introduced here is for the purpose of setting fire to the paraffin deposits which are in the well. His invention is based upon this, in that it consists in burning out the paraffin by means of oxygen or other combustible gas introduced into the well by pipe or otherwise, and igniting it in the presence of the paraffin so that it would be necessary to put in oxygen or air, or some combustion supporting gas, in order to carry this process out.

I had reached the Oliphant patent, Oliphant and Lyddon, No. 797529, in which he proposed to set a fire in the well, which would have the effect of increasing the production.

I will now go to the second section of my classification of this first group of patents, involving the use of heat, wherein heat in this instance is generated in the formation itself, and, as an example I refer to Gardner 1,372,743, is-

sued March 29, 1921. He proposes to pass an electric current from one well to another, thereby generating heat within the earth formation, and that will serve the purpose of moving oil towards the collecting well. He connected the output terminals of an electric generator to the tubing of two wells, that is to say, the positive terminal of this output generator was connected to one of the wells and the negative terminal to another well; the generator, the two wells and the earth formation forming the complete circuit for the passage of the current through the earth. The Court:

Well, how would they fix it so that it wouldn't start to cross long before it got down to the bottom of the tube? A. I don't think he could prevent that. Nature would decide where that current is going to go after it goes in one well and crosses to the other, the path it takes between the two is not under control. You have no control of that. The patent states: "The operation of my improved system for removing obstruction to the flow of fluids in earth strata is as follows: An electric current of sufficient voltage to overcome whatever resistance there may be in the circuit described to maintain a watt output power to increase the temperature at the bottom of said well and in the strata between said wells to a degree sufficient to liquify paraffin, asphaltum, and other obstructing residue of petroleum, and to increase the gas pressure by heat, thereby forcing or blowing movable detritus from out the interstices and crevices of the rock adjacent to said wells."

I come to a new section now where the principle of operation is to convey heat into the well by something that had to be heated on the surface of the ground. A simple illustration of that is the Phlager and Lobdell patent, No. 56,987, dated August 29, 1866. In this case the method of conveying the heat to the bottom of the well is analogous to the hot water coil in a hot water heating system. There is nothing to indicate how deep a well they had in mind. However, if one considers the date of issue of this patent it must be with reference to such wells as were known at the time.

My understanding of the depth of those wells is that they were relatively shallow. I think the Drake well was 70 feet and other wells were drilled about 450.

Patents of this same type were still issuing as years went on. Here is one dated November 4, 1930, to C. Larsen, No. 1,780,428, the purpose of which was to clean the bottom portions of the oil well by the dissolution and mechanical removal of obstructive matter such as mud, paraffin, bentonite, salts, asphaltum, and other things which frequently fill the crevices and interstices of the formation and thereby prevent the oil from flowing into the excavation. He attains this object by producing in the bottom portions of the well a whirl or vortex of a hot fluid fraction. That is accomplished by lowering a device into the well on the end of a tubing, a device of laterally arranged jets whereby steam is forced down the pipe, force the pressure down into the well and squirt out into the hole.

Now, I pass over into the next group, the major division group 2, under the heading of "Chemical Solvents." I would prefer to pass these over at the moment, as I intend to refer to them later, and go to the patents in this major group, the second division, involving the use of non-chemical solvents, by which I mean solvents of the type that take into solution certain materials without undergoing chemical reaction with those materials. Water would not be one of these, because water as far as I know dissolves very little, if anything, in the base of an oil well, or similar well. If you had a lump of dirt down in there, water would dissolve the lump, but not in the sense in which I am using the word; that is, for example, the operation of taking sugar into solution in water, that is the kind of a solvent I have in mind here, and that reflects the type of solvents that are shown in these various patents. They are solvents that truly dissolve some of the substances in the base of the well.

The most typical of these I have here is a patent issued to Edward A. L. Roberts, No. 119,884, dated October 10th, 1817. He sets forth the well known problem that some of

the others set forth, that the oil bearing rock becomes gradually chocked up by the accumulation of paraffin and other substances contained in or deposited by the oil, so that the yield of wells after a time gradually decreases, and he suggests to employ what is here called benzine as a solvent for dissolving those deposits. And, of course, that merely means a distillate from petroleum gasoline.

The Court:

Maybe to somebody else that sounds just as impractical as the heating method, but to my mind that sounds better. A. This is much better. I know this type of thing is used today for the waxy or paraffinic deposits.

The Court:

I think that sounds as if it might be practical for the thing it is intended for? A. Yes, it is. Coming to the third group here classified by me as re-pressuring, the first one I have here is to Mark D. Mitchell, for oil flushing system, patent No. 825,745, dated July 10, 1906. According to this specification, the method embodying the features of the invention consists in supplying and driving the medium under pressure to the oil bearing stratum, within an effective radius or proximity to one or more oil well pockets. The compressing medium used for this driving effect may consist of air, gas, or other fluid, to which may be imparted a force sufficient to overcome any laxity in the forceful operation desired in the pocket or chamber by an extended, long conveyance to the hole or opening.

That art continued to develop, patents issuing, for example, to I. L. Dunn, 1,067,868, dated July 22, 1913, in which he proposes to pump back into a well a quantity of gas until he restores the pressure. He proposes to pump gas back into the formation where it re-dissolves, dissolves in oil, and then after he has thereby restored the rock pressure, then he will open the well and allow it to produce. Of course, he would get back some of the gas that had been pumped in, but after a time the oil would enter the well because it would be carried through the hole by the gas seeking to escape from the oil in which it had dissolved. This

one is not the drive type. The drive type I think is the one that was referred to by Mr. Lewis, wherein the repressuring gas is put inside, put into certain wells, but the oil is recovered from some other, to which the oil was driven; but in this instance he puts the gas down the same well that he later withdraws the oil from. Now, the patentee states that natural gas may be the pressure medium employed "or I may use any other permanent gas which may be cheaply manufactured but preferably I employ air which when forced into and through the rock upon its return not only has the effect of driving out the oil but also absorbs the lighter hydrocarbons to a greater or less extent thus becoming an inflammable mixture which may be burned or used for any of the other purposes to which carbureted air is put or, if preferred, the gasoline or other hydrocarbons contained in the air and which are capable of condensation at ordinary temperatures may be condensed, the air thus forming a convenient source of volatile hydrocarbons."

Now, this pressure restoration or injection of either air or hydrocarbon gas as the case may be, is effected by large pumps and that is being done on a large scale in many fields. They use several thousand horsepower of compressors turning gas back into wells to re-pressure pools. Of course, this process is directed to a single well, but a whole pool may be re-energized this way. The injection pressures used may run up to two or three thousand pounds per square inch, and they use two or three stage compressors to reach that pressure.

Regarding the length of time that will be consumed in making one of these repressuring operations, the patent states beginning on the last line, column 2, page 1—"But in any event the forcing is ordinarily continued until the required pressure is attained and may extend over a period of several weeks, months, or even longer. During this forcing operation, of course, every effort is made to retain the pressure and prevent the gas escaping either at any of the wells or elsewhere."

Mr. Lyon:

Just for the purpose of the record, your Honor, can the witness identify for us a particular location or particular type of operation as being used such as he has described, so we will know what he is talking about? A. I have reference to some of the recent issues of the Oil and Gas Journal. In fact, you can find advertisements on these repressuring pumps in almost every weekly issue that comes out.

Patent 1,735,646 dated November 12, 1929, issued to James O. Lewis, is another example of repressuring. The particular feature of this invention is a method of using air and natural gas alternately and in such manner as to avoid the formation of explosive gas mixtures during the injection.

As to whether that was the Mr. Lewis who was on the witness stand, there is no way of telling that from here, other than the printed matter which appears on the copy. I will read that. "James O. Lewis, of Tulsa, Oklahoma, assignor by mesne assignments to Dunn & Lewis of Tulsa, Oklahoma, a partnership, composed of Ervin L. Dunn and James O. Lewis."

Mr. Owen:

That, I think identifies him, Your Honor, he having testified as to that firm name.

The Court:

Yes, and that his name was James O. Lewis.

Another patent, issued in this classification is 1,816,260 dated July 28, 1931, to Robert Edward Lee, in which he proposes to drill lateral channels from a well at one level in the producing formation and then another set of lateral channels in the same formation at a lower level, and then inject gas from one set of channels to the other to force the oil out. And this type of thing continued on until I have here a patent to Robert E. Strait of Bartlesville, Oklahoma, assignor to the Empire Oil & Refining Company, 1978655, dated October 30, 1934, issued on an application filed November 27, 1926. That keeps it within the date that you

have requested, Mr. Owen. This has to do with increasing the production of hydrocarbons from oil wells in which a gaseous pressure medium is forced into hydrocarbon-bearing strata penetrated by the wells.

That now brings me to the patents in Class 4 entitled "Flooding." In this connection I might state that I have very few patents, in fact, I only have three. But it illustrates the fact that there are such patents, and, of course, we know there are such processes. This patent in this class, which is an indication of the type of thing, is 1,651,311, dated November 29, 1927, to Howard Atkinson, for recovery of petroleum from oil bearing sands. With reference to this invention of his, in connection with oil bearing sands, from which it may be difficult to extract the oil. He means sands in the broad sense. It may include acid soluble production formations, or non-soluble, or both. However, the use of this type of process has generally been confined to such formations as are practically not soluble in acid, as the sandstone comes within the type of porosity enough to carry out one of these processes, whereas limestones are like this desk, they are very impervious, they may crack, but they are not very porous.

Mr. Lyon:

Do you have in mind in that connection the flooding as they practiced it in Pennsylvania for forty or fifty years, to increase the production of the wells there? A. That is the type. This patent is not a very good example of that, because it relates to improvements in connection with that. It is not the first or earliest patent on this subject. In the patentee's words, he states:

"The object of the invention is to provide a method whereby oil or petroleum may be extracted with facility and in profitable quantities from oil wells from which oil has been extracted until they have ceased to produce oil in what is generally considered to be profitable quantities, and especially from oil wells which have become flooded with water and abandoned, as, for example, so-called edge water wells. * * *"

"The present invention provides a method whereby a large quantity of the oil which will not drain naturally from the oil bearing sand and hence remains after the extraction of oil therefrom in the usual way has been completed is recovered. It is based upon the discovery that when a mass of sand wetted with oil or petroleum is at ordinary temperatures submerged in water to which is added any strong alkali, the oil contained in the sand is within a short time removed from the sand in a body, leaving the sand practically clean and free from oil."

The Court:

Tell me in your own way how it is that they propose to get the oil out of this rock. A. They will introduce into one or more wells this water, and while that is going on they will pump other wells in the vicinity of the injection well. They put that water in under pressure, if necessary. In some instances they let it flow in by gravity from an upper stratum. The water stratum up above might be tapped by holes in the casing and let that water run down and it will enter the oil bearing stratum below and force the oil into the recovery well which can be collected in this pool.

Mr. Lyon:

What you call water drive, isn't it? A. That is the common term, yes.

The Court:

They put the water, we will say, into this hole without pressure, the tendency would be, if nothing happened, for it to rise to an equal height in some other well that they pumped the water out of. A. Yes.

The Court:

And the tendency would be that as it picked up the oil on its way, the oil being lighter would go to the top of that, I suppose. A. I think that would be a correct theory of that.

The Court:

With some success, possibly.

Mr. Lyon:

Of which you take judicial notice. It is in the 1880 census. They published an elaborate book or volume of the 1880 census describing all the methods that the Bureau of Mines then knew that they were using in the oil industry in the United States. You find a full account of this water drive in there.

Mr. Richmond:

The idea is to put in your water over one edge of your field or whatever you are going to drive for, and drive it towards your next well, and when the water shows up there you go ahead and put your water in there and go ahead and take it out of another well.

The Court:

How far? It wouldn't exceed a mile, would it?

Mr. Richmond:

I don't think it would be that far, Your Honor. I don't think it would be over a quarter of a mile.

Witness continuing:

I believe we have covered enough as to flooding to illustrate the type of process that is, and now we come to this last, second to last group, namely, No. 5, in which I have put the vacuum type process. I have one patent here illustrating that, No. 1,858,847 dated May 17, 1932, to P. L. Young. He proposes to connect the well casing to vacuum pumps and at the same time by the injection of a gas down a tube and through nozzles in the bottom of the hole, to create suction down there. They are both doné in the same hole. He is withdrawing a gas from the hole at the same time that he is using a gas jet pump in the bottom of the hole. He is producing the maximum possible vacuum at the bottom of the hole because it is there that he operates this jet pump which does the sucking, in addition to the vacuum pump that is at the top of the well. It aids in getting the most reduction in pressure that he can get in a well hole.

The Court:

Does it mean, then, that he has a suction at the top and

there is another suction at the bottom? A. It makes it easier for his purpose apparently to do it that way. But, he cannot, in any event, secure a greater reduction in pressure than the lifting off of the atmospheric pressure. All that anyone can do with a vacuum pump is hold off the atmosphere, and that is all he is doing but in a complicated way.

The Court:

He was figuring, perhaps, that the suction of his pump at the surface wouldn't be big enough so that when he got to the bottom of his well his vacuum wouldn't be very good. A. There is something in that, I believe. He states in his own words that, "The present method is an improvement of the processes for obtaining gas and vapors from oil wells under high vacuum by which higher vacuua may be obtained in an extremely efficient manner directly on the producing sands." That is his view of what it is he is trying to do. However, this patent is illustrative of the fact that there are patents in this field of vacuum operation of wells.

Then that brings me to a miscellaneous class of more or less unrelated things that might be done in an oil well in connection with extracting oil from the ground. The first one of these is dated 1865, No. 49,922, to Isaac Relf, and it involves the use of pressure produced by hammer blows of a piston inserted down the well hole. That was just to compress the air, making shots of compressed air at the bottom.

The Court:

Awfully small around the opening. Isn't that what he is hoping for? A. That is what he is hoping for. It has almost a mechanical way of getting the action of an explosive.

The Court:

In other words, it is different from what you had before of compressed air? A. Yes.

The Court:

But this is to compress it in shocks? A. That is the sort of thing it is.

The Court:

I should think that would almost come under compression, that is, air compression, or something— A. Yes, it could be, although it is a mixture of the mechanical and so on.

The Bureau of Mines has put out a publication dealing entirely with the vacuum operation of wells, and it is a better publication of that art than one could find in the patents themselves. I believe the date is about 1930. It summarizes the past history, of course. It shows that vacuum has been used on wells for many years in different places, as one of the methods of stimulating the recovery of oil.

Mr. Owen:

I am now going to make the offer of the copies of each of the patents referred to by the witness, merely for the purpose of illustrating what the witness has testified to, and for the convenience of the court, if he cares to look at them. When it comes to an appeal record, I, of course, do not expect to put them in.

The Court:

I will say this about the appeal record, they are not to be printed in that record.

That would be too expensive, and you ought not to do it. I have the privilege of looking at these in connection with this testimony. I doubt if I will find occasion to do it, but I have that privilege, and I reserve that same privilege for the Court of Appeals.

The Court:

By the way, which one of these classifications now does our method here in suit fall into? A. That was under the solvents, and I excluded that class from my discussion.

I can't place an exact number on the patents in these classes. But as I said before I believe my files of patents relating to the production of oil by means of wells cover some two thousand or three thousand patents. Those specifically directed to methods of treating wells involve some two hundred patents and, of course, the ones that I selected

out of that are a smaller number still. But, I did not include in the patents referred to those involving the use of chemical solvents. This will be up to June 30, 1932.

Mr. Lyon:

Are these all the patents there are in the Patent Office on those subjects, or just the number you happened to have when you made the estimate? A. Those are all I have found in connection with my business of locating these patents.

Mr. Lyon:

Now, similar patents or patents on this same subject have continued to issue since 1932, have they not? A. Oh, yes, indeed, and are still being issued today. There has been an enormous increase in the rate of issuance of patents since the issue of Patent 1,877,504. That is the Grebe-Sanford Patent in suit.

Mr. Lyon:

You mean in all of these different fields? A. No, in the special field of the use of acid in a well.

Mr. Lyon:

But how about these other fields; have the patents continued? A. They have been coming out, but I don't believe that the rate has been anything like—there has been a growth, of course, but the rate of growth there is nothing like what it has been in that special art.

Mr. Lyon:

What I am getting at is this: Since 1932 patents have continued to issue in these classes that you have mentioned here today, at least as fast a rate as they did before 1932, and to some extent faster? A. I think that is correct, although I haven't specifically computed those rates.

By Mr. Owen:

Q. Now, will you take up the field of patents in which solvents of one kind or another are used and which I understand you omitted from your previous classification? A. I omitted the solvents which I have called chemical solvents wherein the solvent action involves a chemical reaction, too.

Q. Will you take up that line of patents and explain

approximately how many there were prior to 1932, and what they cover?

The Court:

Does this question apply to just chemical solvents, or all kinds of solvents?

Mr. Owen:

Chemical solvents.

The Court:

That means where there is a chemical reaction?

Mr. Owen:

Yes, Your Honor.

A. My recollection as to the number is that there are about ten such U. S. patents. I may be in error by one or two, but they well—the correction will appear as we go on.

Up to June of 1932, or the filing date of the Grebe-Sanford patent in suit. The first of—

Mr. Lyon:

(Interposing) Would you give us at the same time the number that have issued since? A. Yes, I can tell you approximately. I think there are 71 more issued from the period of—that is, on applications filed since June 30th, 1932, until some time in 1939, there were about 71 patents issued on applications filed during that interval, while there were about ten patents issued on applications filed in all the previous interval up to that time.

Q. (By Mr. Owen) And what is the distinguishing feature that applied to those ten patents issued prior to 1932 and those 71 patents which have issued since on applications filed since 1932? A. I am not sure that I understand the question, Mr. Owen.

Q. Did all of them utilize acid in a well for one purpose or another? A. Yes.

Q. And then, as I understand you, the number of patents in which acid was introduced into the oil well, or any other kind of well, prior to 1932, was ten, and that since 1932, the year when the Grebe-Sanford patent issued, there have been 71 patents issued in that respect?

The Court:

Eighty-one; 71 on applications filed since that date, and ten on applications that had been filed prior to that date.

Q. (By Mr. Owen) Do you understand? Is that right? A. That is my statement, subject to perhaps the correction of a few numbers one way or the other.

Mr. Lyon:

Your Honor, can I ask a question? Are you speaking now of all patents using acids to dissolve formations, or wax, or some material on the formation, or are you talking about all patents involving any kind of chemical solvent, whether it is the acid or not? A. My number I gave was limited just, subject to correction, to such patents as involved the use of acid in wells for any purpose. They are limited to acids with or without other things.

Mr. Lyon:

Aren't there a great many other patents that show one kind of chemical solvent besides acids for use on a well. A. Not as far as I am aware.

Mr. Lyon:

Have you looked for them? A. Yes, sir.

The Court:

Just give one example of what you have in mind?

Mr. Lyon:

Some of these Tretolite patents. Tretolite Company has a whole line of patents for paraffin removing that are not all limited to acids. A. I don't know of any that are involving the use of acid in a well.

Mr. Lyon:

That is where I am mixed up here somewhere. They have a line of patents on the use of solvents for putting down wells, have they not, the Tretolite Company? A. I am not aware of it, that they have such a line.

Mr. Lyon:

Well, they have. As you say, has your search been such that it would reveal whether they had any or not? A. I believe it would have.

Mr. Lyon:

Then you say they have not any patents on solvents for removing paraffin from wells?

Mr. Wiles:

He said chemicals.

The Court:

Chemical solvents? A. I do not know of any.

The Court:

Just call his attention to one.

Mr. Lyon:

I have not got them here. I will have to get them and give them to Your Honor. There is a whole series of them.

The Court:

Then you find one and bring it here before you get through with it, and call it particularly to his attention.

Mr. Lyon:

Yes.

Mr. Wiles:

The witness has limited this to chemical attack.

The Court:

That was the reason I did not know but what there was some misunderstanding.

Mr. Lyon:

I think there is.

The Court:

I think it would be better if we could solve it at an early time. As quick as you find a patent that will illustrate what you are asking him about, call it to our attention.

Mr. Lyon:

Are these chemical solvents limited to those that will attack paraffin?

Mr. Wiles:

They will attack something—

Mr. Lyon:

For instance, mud, in a well, a well is muddied up, and you want to get some of that mud [redacted] as to open it up so that it will flow better. They use a chemical for that.

Mr. Wiles:

Chemicals that will attack something and make a chemical change.

Mr. Lyon:

Then maybe I have misunderstood you.

The Court:

That is not the chemical solvent, is it? That is what I was in doubt about. They explanied to me a little while ago, and I think I was asking some questions that if mud does not enter into a chemical change, but it just entered into a solution, or whatever you call it, it would be in the water, and that would suspend—is that right? A. That is right.

The Court:

That would be anything that would soak mud up, soak down the lump and let it float around in there, but that would not be included in the chemical solvent any more than it would if they put water in there and stirred it up?

Mr. Lyon:

(To the witness): Is that the reason that you eliminated from this class some of these Tretolite patents, or didn't you look at the Tretolite patents? A. I believe I have a couple of hundred of Tretolite patents in my collection, and I looked at them.

Mr. Lyon:

Some of them would have come into this class if it were not for this feature of solution? A. I can think of one or two that might have. There is one of the Tretolite patents—I don't recall the exact date, whether it is 1931, perhaps, or 1933, somewhere along in there, which involves the use of minute amounts of carbon tetrachloride in the water introduced into the well while it is producing, to prevent the formation of paraffin deposits. But, as far as I am aware, there are not any Tretolite patents that have to do with the use of an acid in the well for any purpose, or that have to do with increasing the production of a well in any way.

Mr. Lyon:

Do you happen to remember one, a Roberts patent, on putting a modified fatty acid down the hole to prevent the formation of emulsion that would interfere with the production of oil? A. I think there are quite a few such patents. As I understand their disclosures, they have to do with treating wells that are producing and while they are producing. It has nothing to do with the art that I have collected here.

Mr. Owen:

I have a chart, if Your Honor please, prepared by the witness to illustrate the point that has just been brought out. It is a little bit out of the order in which I intended to produce it, but in view of the fact it has now been brought out, I will have this chart marked Plaintiff's Exhibit 9 and will ask the witness to explain what it shows.

(Marked Plaintiff's Exhibit 9.)

The Court:

I will say this to counsel for Halliburton, any time you find such a patent I will be glad to stop and let you interrupt to let you show it to the witness and inquire about it, if you do find it.

A. This chart shows by this scale on the left the number of United States patent applications which issued into patents. The scale along the bottom is the year, corresponding to that number. The curve has been plotted with reference to these two scales, beginning in the year 1865, because that was the first year at which I found an application issued into a United States patent mentioning the use of an acid in a well. That was the Sherwood patent, issued in 1865. Then around this time (indicating) more patents issued, and as more issued and as time went along, this curve went up very slowly.

By Mr. Owen:

Q. How many had issued up to 1900, say? A. By 1900 there had been 5 patents issued on applications filed up to that time. Then we come to about what appears to be 1922 on the chart we perhaps have six or seven patents

issued by that time, six perhaps. The exact number we can determine by a reference to the issued patents and counting them up. We get along to 1930, there were then 10 issued patents on applications filed up to that time, and then I believe there were no more issued until the Grebe and Sanford application was filed and issued. Thereupon there was an enormous immediate growth in the number of applications issuing into United States patents, so that by 1939 there were more than 55 patents that had issued on applications filed up to that time.

The line indicating the issuance of patents involving the use of acid in a well since 1932 does not include patents that issued on applications filed by the plaintiff, The Dow Chemical Company. From this chart have been excluded the plaintiff's applications. But in the numbers that I have previously mentioned in my testimony I have included all the patents that I know about.

The Court:

You say you excluded applications of The Dow Chemical Company? I understood this was a chart of patents issued? A. Yes.

The Court:

Does it include patents issued to Dow? A. Only the Grebe and Sanford. And this chart shows nothing about pending applications. These all have become patents. The chart is according to the dates when the applications were filed. It is patents issued but it is by filing dates. The chart does not include any application which is still pending nor any application which has been rejected and abandoned during this period, because my numbers are taken from issued patents.

The Court:

But you have gone into this and if I were to make another little dotted line here (indicating) that showed the date patents issued, that would come clear up to today over into the '41 column, it would be here? A. Yes, sir. As a matter of fact, the steepness of the curve which shows the rate of growth might be steeper than this is, because that

might bring out still more patents pending we don't know anything about.

By Mr. Owen:

I have another chart which I will ask to be marked Exhibit 10. (Exhibit 10 marked.) This chart will be referred to as Streams of Knowledge Chart. I will ask the witness to take up, first, the patents which are listed under the title Stream 'B Knowledge of the Use of Acid in Oil Wells, in view of the fact we have just been considering that subject. That is the column on the right of the chart. A. The first patent in that column is 57,982 dated 1866 and it is for improved method of removing obstructions from oil wells. That patent teaches to bring acid into contact with an obstructing tool which may be in the well hole, for the purpose of eating away either the tool or the surrounding rock, or both.

The Court:

You can loosen it and get it out? A. Yes, or if you wish, you may dissolve the tool completely in the well hole. The corroding and the decomposing action of sulphuric acid upon iron and steel is well known and it is used in this process, or any equivalent acid. The acid is brought into contact with the obstruction by means of a small tube, and then—or, it may be brought into contact with the obstruction by means of a glass bottle or cylinder, the bottle being allowed to strike the obstruction and break, and empty its acid contents on it, thereby dissolving and making it possible to remove the tool. The acid is described as hydrochloric. That would take care of hydrochloric particularly, as it has a similar economic status and it is presumed to be similarly corrosive. It was broad on any kind of acid that would eat iron.

The Court:

Or any kind of rock? A. Or the rock.

The Court:

So that if they had a rock that some acid was particularly good for, they could use that kind? A. That is true. As he states,—"The acid will also act upon the rock

and will decompose portions thereof in which the tool is wedged and thereby quicken and render more easy this method." He also states in connection with introducing the acid, a copper barrel may be used to lower the acid to the obstruction.

The next patent on the list is dated 1873 to Looney, No. 139,010. His application was filed in 1872, and he makes use of an acid in an oil well to generate heat by reacting the acid in the well hole with an alkali. Potassium hydroxide is the alkali, although the patent uses the old language, a solution of potassa. That substance, of course, is a solution of potassium hydroxide.

By Mr. Owen:

Q. What does that patent have to say about how the acid is gotten into the well? A. I don't recall finding any special instructions about introducing the acid into the well. It should be noted, however, that he first places in the well this alkaline solution, and, of course, that will neutralize the acid subsequently introduced. That would not be an inhibitor.

The Court:

What would you say it did? A. It would neutralize the acid. That is just another way of saying it would react with the acid and turn it into something else which is not an acid.

The Court:

The purpose of this, what you have got I see is by that reaction to produce heat and melt something that they thought would plug it up somewhere? A. Yes. The patentee states that his invention relates to cleaning the well of paraffin and other similar resinous compounds which impede the free flow of oil by means of chemical ingredients, and it consists of what we have just mentioned. The sole method of doing it was by the reaction of creating heat and melting the stuff so that it would—

The Court:

Why wouldn't it get cold and go back and do the harm all over again? A. It would. And, he provides for that by

putting some benzine in afterwards. That keeps the melted paraffin in solution.

The next patent is dated 1896 issued to John W. Van Dyke on an application dated 1895, No. 556,651. The Van Dyke patent relates to a method of increasing the flow of oil wells in limestone formations and that is accomplished by the introduction of sulphuric acid into the well through a special pipe, the acid being then forced into the producing formation where it reacts chemically on rock, producing other material which is removed by subsequently washing out the hole in the formation.

The Court:

This is the first one that does—that attempts to do what our patent in suit does, namely, eating the rock? A. That is correct. It eats the rock in which the oil is coming to the well; it eats the oil bearing rock.

Q. What does that patent state about the means of getting the acid down into the well? A. Well, the patent specification states the following: (reading) "The following is a description of what is considered the best mode of carrying out the invention, reference being had to the accompanying drawings which form part of this specification, and in which—

"Figure 1 is a diagram of a well with the supply or reagent introducing pipe in place.

"Figure 2 is a detail view illustrating a mode of protecting the said pipe; the pipe A is provided with a rubber packer B in the rock above the Trenton limestone C in which the well is. It may be enameled or lead lined pipe, externally coated with enamel or lead below the packer B, or it may be otherwise made proof against corrosion. There is a box D provided with a funnel-shaped bottom to feed the acid to the pipe A. As shown in Figure 2, the pipe A is lined with a tube 2, of soft rubber, and covered exteriorly with another soft rubber tube 3, the lower end of the inner tube being turned back over the pipe A, and also the outer tube, and the whole wrapped to prevent ingress of liquid at the joint."

The Court:

Isn't everybody agreed that that patent that he has just referred to of 1896 is, so far as eating the rock is concerned, exactly like the patent in suit? He had that idea just as completely as the patent in suit, but when it came to preventing the misfortune of that acid destroying or eating the iron of the tools of the well, destroying those, he had an entirely different scheme of matter, isn't that true? Is there anything wrong with either one of those statements, that one is exactly alike, and the other is entirely different?

Mr. Owen:

The only addition I would make to your statement is that in this particular patent, sulphuric acid is used instead of hydrochloric acid. The next patent used hydrochloric acid, or is supposed to, but at the same time I want to call Your Honor's attention to the fact that although the action of the hydrochloric acid is the same when it gets into the formation, it is now known to be the same when it gets into the formation whether it is uninhibited or inhibited acid, it was not known at that time, and it was not known at any time prior to Grebe and Sanford patent that an inhibitor could be used which would not in some way affect the action of the acid when it got down into the oil well.

The Court:

Well, I thought that covered my second proposition, that it was entirely different as to how he was going to—he didn't have the idea at all, I thought, of actually protecting the tools.

Mr. Wiles:

That is right.

By Mr. Owen:

Q. Now, take up the next patent and explain that. A. The next patent which issued actually concurrently with the prior numbered patent to Van Dyke is that numbered 556,669 to Herman Frasch who assigned one-half to John W. Van Dyke. Van Dyke also assigned one-half of his to Herman Frasch. And the drawings are signed by Charles J. Hedrick in both instances.

Q. And, isn't it a fact that the drawings are the same in both instances, and that the specifications are almost word for word in both instances except the Van Dyke refers to the use of sulphuric acid and the Frasch patent refers to the use of hydrochloric acid? A. That is what I gather from the reading of both these specifications. There are differences in statement as to the chemical effects produced by the two acids, of course, because in the Frasch patent the reaction of acid on the rock is to produce a calcium chloride solution out of the rock, whereas the action of the Van Dyke patent employing sulphuric acid is to convert the solid limestone into a suspension of calcium sulphate which can not be forced out of the rock pores.

By Mr. Owen:

Q. Now, will you take up the next patent on that list? A. There is some of the Frasch specification, perhaps, that differs from the other that might be included. It states that after a rest of, say, twelve hours, milk of lime is pumped down to neutralize any trace of acid that might exist. The well is then cleaned out and the tubing replaced.

The Court:

That was to check further eating. They had the danger that might come if it kept on eating and ate out into the brine, I suppose? A. I presume that is so.

The Court:

Does Frasch also describe protecting his metal in the same way? A. The description of that is practically identical with that in the Van Dyke patent, the means of protection being to employ an enameled, lead-lined or rubber-covered pipe.

The Court:

Aren't there any acids except sulphuric and hydrochloric acid that will do the trick? Aren't there some other acids? A. Yes. There are many acids which will form solutions with calcium carbonate. There are a great many that will do that. But, as to how many acids there are which will dissolve oil producing rock is something I am not prepared to answer.

The next patent reference on the B side of the chart is a patent to George L. Ball, numbered 670,577, dated 1901, the application being filed in 1900. He makes a disclosure of introducing an acid into a well, and an alkali to react and produce heat. It is similar to Looney. However, this patent discloses also that in order to put the acid in you may employ a dump bailer. The patent states:

"The chemicals may be introduced into the well by dropping or pouring them therein and, as they are heavier than the oil, they sink to the bottom of the well, so that the heat is generated in the cavity where it is required; but the chemicals, or at least the acids, may be put in an ordinary bailer, and lowered into the well and then dumped."

By Mr. Owen:

Q. Will you explain the operation of these dump bailers to which the patent refers? A. I am not well advised in dump bailers. However, it is my understanding that it consists of a length of pipe of such diameter as will enter the well and be capable of being lowered to the bottom, and at the lower extremity of the pipe there is some sort of valve means whereby the contents of the pipe may be emptied when the lower end of it strikes the bottom of the well, by a kind of a trip arrangement.

Mr. Lyon:

It is just a bucket that you can drop on the bottom of the well and it will then empty its contents.

A. (Witness continuing): On the chart there is next shown a 1923 reference of Mills. It is a Bureau of Mines report of investigations, Serial Number 2550, to which Mr. Lewis has made reference in his testimony. It is Exhibit 8. There is a portion of that report that refers to the use of an acid in a well, and my recollection of what I heard from Mr. Lewis is that that portion of this reference has already been read into the record. On page 9 the use of hydrochloric and sulphuric acid both are mentioned. It describes what we have been finding heretofore in the patents, and in addition this bulletin of the Bureau of Mines also makes this statement with regard to sulphuric acid:

"Sulphuric acid should not be used in oil wells because of the danger of plugging the sands with precipitated sulphate salts, more especially calcium and barium sulphate."

The next reference is patent 1,410,827 issued to William F. Muehl, dated 1922, on an application filed 1920. It is for a method of cleaning oil wells. For that method he states that he uses acid. He introduces a suitable acid, such as hydrochloric acid, which will attack calcium silicate and other accumulations, to clean a well—

The Court (interrupting):

It's the same chemical action we have been talking about but he doesn't seem to be thinking about its going out inland but, more, he thinks this lime from the rock is going to get down in there and into the well proper and he wants to eat that out.

Witness continuing:

That is true. The use of the acid is more local than in the Frasch or the Van Dyke patents.

The Court:

Does he say anything about how he does that? A. Yes, he does. In fact, his specification includes a drawing of an apparatus showing a means for getting the acid to the location where he wants it to work, and it consists of a dump bailer similar to the one previously described, but for the valve in the lower end of the bailer he has provided zinc closures, a form of zinc disk. And these, of course, are dissolved by the acid, thereby emptying the bailer after a time. The discs last long enough to permit the acid to be lowered into the well.

Regarding the number of discs to be used, the patent states that these can be varied according to the length of time that the acid is to be allowed to remain in the bailer.

Quoting from the patent: "I prefer to use hydrochloric acid, which readily attacks zinc, and I prefer to have the zinc wafers or discs of such thickness that a given time will be required for the acid to eat through each disc. By way of example, each wafer may be designed to resist the acid for five minutes; therefore, if it requires five

minutes to lower the receptacle from the top of the well to the point of discharge, one disc will be placed in the bottom of the receptacle. If ten minutes are required, two discs will be used; fifteen minutes, three discs, and so on."

Mr. Lyon:

I call Your Honor's attention to the fact in that patent, page 2, line 22, the inventor says: "The particular advantage of providing the container is that the acid may be applied locally in the well, thereby reducing the quantity to a small portion of that which would be required if it were necessary to pour the acid from the top of the well." So the inventor was deliberately just putting down a bucketful of acid and calls attention to that is why he uses a bucket—because he doesn't want to use as much acid as would be involved pouring it down the pipe.

Witness continuing:

Another feature about that disclosure is that the size of the bucket which can be introduced is obviously small because he puts it down through the innermost tubing of the well.

As to whether there is anything to indicate the character of the formation in which this invention was intended to be used, I think the disclosure in the specification of the problem that this method was intended to solve indicates that the producing formation would probably be unaffected by the acid because the invention seems to be directed towards removing the accumulation of paraffin, calcite or acid-soluble deposits.

The Court:

And the amount of it indicates, as you say, a small amount, so he evidently wasn't thinking about getting out into the rock formation but getting some accumulation in his well.

Mr. Lyon:

Page 2, line 17, he refers to the lime or silicon or other accumulations on the side clogging the walls or screen will be relieved of the accumulation, and the oil from the surrounding stratum may flow into the well unimpeded. So I

don't see anything in here to say it isn't a limestone well, because he refers to lime. A. No, I found no reference to lime. It refers to calcium, silicon and other accumulation.
Mr. Lyon:

You don't find any reference to lime? I call your attention to line 17, page 2 of the patent. A. Yes. But that, of course, taken with the statement on the previous page, as to the deposits which are there, would seem to indicate that he is not talking about the structure of the producing formation.
Mr. Lyon:

How could there be any lime in that well along the walls if there was not lime in the formation into which the well was dug? A. There is no necessary connection between the existence of lime deposit in the sand well and the producing formation's composition.
Mr. Lyon:

Well, the lime must come from the formation in the well somewhere. A. That is an assumption.
Mr. Lyon:

What? A. That seems to be an assumption. There is no necessary connection between those facts.

The next patent is one issued to Lake and Phelps No. 1,498,045, dated June 30, 1924, on an application filed in 1923. His invention relates to a process of cleaning wells and apparatus therein, and it has for an object a provision of a novel process which readily removes colloidal muds, clays, etc., from the walls of the well hole or from any ap paratus or members within said well hole, and which muds would tend to clog or otherwise obstruct the flow of oil or gas through such apparatus or well hole.

Some acids chemically react with mud, or with clay, depending on the composition of the clay, but in this process according to the specification as I understand it, the way he states it at any rate, is that the acid solution seems to have greater affinity for the colloidal muds than it has for the metal casing through which the acid is introduced into the well hole. It would appear that the acid would re-

act quite readily with this mud, maybe far more, maybe so readily that it does so more actively than it does on the metallic part of the well.

Mr. Lyon:

Would you read that particular part to the court beginning at line 100, because here is a man that says this acid which includes hydrochloric, if handled properly in the pipe will not injure the pipe. A. I don't gather that from this specification.

Mr. Lyon:

Read beginning at line 100, will you please?

"It is found that the acid or acids used for these purposes will not appreciably attack the metallic structures in the well hole such as tubing and casing, collars, and the like, where mud is present in the hole, unless used to excess, inasmuch as when an approximate balance between the amount of acid and colloidal mud is maintained, the acid action will be expended upon the mud rather than in attacking the metal."

The next patent is Tilton, No. 1,608,869 issued in 1926, on an application filed in 1922, and renewed in 1925. He proposes to generate a heat in a well to melt paraffin using the action of concentrated sulphuric on water followed by a neutralizing sodium hydroxide.

The Court:

Now, what did he have that was new over Looney and somebody else? He had that idea of having a chemical reaction creating heat and melting paraffin. A. There is this possible novelty in it, there may be, of the use of a concentrated sulphuric acid, which, when added to water, liberates a large amount of heat, and then after that heat has been obtained he can get a further kind of heat by neutralizing the acid solution previously formed, using sodium hydroxide for the neutralization.

The Court:

Did he put them in separately? A. Yes.

By Mr. Owen:

Q. What did the patent state or show as to the meth-

ods used for lowering the acid into the well hole? A. It is my recollection that the container used for this was a lead-lined container. The patent states, beginning with line 89 of page 1: "The acid container proper is an elongated receptable, provided at its lower extremity with a valve discharge orifice 4. The valve for closing the discharge orifice 4 comprises a stem 5, extending through the orifice, and a head 6 lying within the receptacle. The head 6 of the valve comprises a conical lower portion 7 arranged to fit the wall of the container adjacent the discharge orifice 4, and an upper portion 8, which is shown as conical, but which may be of any desirable rounded or tapered form.

"Cooperating with the valve head 6 are a plurality of spheres 9 disposed within the container 1. When the container is lowered into operative position, the valve stem 5 comes into contact with the bottom of the well and moves upwardly within the container. When the valve head 6 moves upwardly, the spheres 9 run downwardly in the container and wedge between the conical portion 7 of the valve head and the corresponding inner surface of the container adjacent the discharge orifice 4. These spheres are of sufficient diameter to prevent them from passing out through the discharge orifice around the valve stem 5, and also to prevent their upward displacement around the valve stem and pass the valve head into the body of the container. If desired, however, the head portions 7 and 8 may be separated by the ridge or bead 10 shown in figure 6 of the drawings, to additionally insure against displacement of the spheres from between the lower portion 7 of the valve head and the inner surface of the container." When the stem 5 strikes the bottom of the well and raises the valve the acid, or whatever liquid is contained in the container,will flow out into the well hole.

The next patent on the chart is the patent to Leo Ranney, 1,806,499, issued in May, 1931, on an application filed in 1928 for a method of facilitating flow from wells. He states, "The invention is especially applicable to the cleaning of oil wells in which deposits of paraffin, calcite or the

like have obstructed the flow from the oil bearing formation."

Briefly he proposes to introduce into the well an acid and a gas-generating chemical which reacts with the acid to liberate the gas. Specifically, he puts in either hydrochloric or nitric or sulphuric acid or other acids or mixtures and then a charge of this gas-generating chemical, as an example specifically noted here is calcium carbide and that reacts with the acid solution making acetylene, and he also states that he may allow that acetylene to be ignited, thereby obtaining additional heat, that is, heat in addition to that produced by the reaction of the carbide on the acid. He does not state how he is going to get air to ignite.

The Court:

It wouldn't burn, would it, down there? A. I don't believe it would burn. Nevertheless, he would obtain the heat of the reaction of the carbide with the acid. He mentions that there will be parrafin in the well and this invention serves to remove those deposits. Acid and gas do not react as far as I know.

The Court:

I think he was doing probably what we have been reading about before where his acid reacted with whatever was in the well, various things in there would be likely to be something that would react with that acid, and in that way he might clean it out. A. Well, presumably he uses enough acid to obtain neutralization, although there is a statement on page 2 beginning with line 18 as follows: "Since the acid is neutralized or almost neutralized by reaction with the added chemicals or the calcite, etc., there is no substantial corrosion of the equipment." In other words he apparently does not use any more acid than is necessary to use up the gas-generating chemical he has put in, and the deposits of calcite, and so forth, that may be there.

Mr. Lyon:

If that is the last one of the patents on this phase of the chart that you intend to include, might I ask why you did not include patent 1,891,667 granted to Mr. Carr of

Pure Oil Company on an application which was a continuation of an application filed April 28, 1932? I am sure you are familiar with that patent and the application. The parent application is earlier than the patent in suit. Why didn't you include it in this Stream B, in Exhibit 10? A. That was not prior art to the Grebe and Sanford patent.

Mr. Lyon:

Do you know that of your own knowledge? It is an earlier filed application, and we have taken depositions here which will show the fact. Here is a patent of the Pure Oil Company that describes all about acidizing wells. The evidence in the depositions show that before Mr. Grebe made any invention at all, that Pure Oil Company came over with the idea to—

Mr. Owen:

I beg your pardon, that isn't true. That doesn't show that at all.

The Court:

Strictly speaking, application is not prior art.

Mr. Owen:

No.

Witness continuing: In making up Exhibit 9 I took this Carr application into consideration. In making up that line I also considered Bowman patent No. 1,809,546, dated 1931, but no others.

The Court:

Then there would be twelve. Then he has got this a little bit above, you see. A. Yes, sir, the 12th application to be filed was the Grebe-Sanford.

The Court:

There were 12 applications filed on which patents later or at some time were issued.

Mr. Owen:

There really would be 11, because this Mills is not a patent.

The Court:

Oh, yes.

Witness continuing: I want to make a correction be-

cause I had forgotten when I made that out as to the number that I had omitted the plaintiff's application. That one is out. So, there are ten, and the Grebe-Sanford patent in suit is the 11th application that was filed up to that time, on which patents at some time issued.

Mr. Lyon:

Well, which one of these kinks on Exhibit 9 represents the Carr application I have referred to? Is that on there at all? A. That comes after the Grebe-Sanford patent.

Mr. Lyon:

You just arbitrarily put it afterward. A. It is chronoligically subsequent to it.

The Court:

Which one? A. This Carr patent has a later number. It issued in December. The application was filed on the same day as Grebe and Sanford.

Mr. Lyon:

And it was a continuation of an earlier filed application, so it states. A. The application on which the Carr patent issued was filed June 30, 1932.

Mr. Lyon:

And this application states it is a continuation of a prior application filed April 28, 1932. A. No patent issued on that application.

The Court:

But, it is a continuation of it.

Mr. Lyon:

Yes. My point is if your chart is exactly as good as stated it was, according to my view the Carr application should come here and should affect this curve and change the curve.

The Court:

In other words, it would make this one a little steeper and this one not quite so steep.

Mr. Lyon:

It would also show that this upturn started with the Carr application instead of with the Grebe and Sanford. That is the significant part of it. But, I am willing to just

have the record show for the present that this curve does not correspond to the curve as it would be if the Carr application was in there ahead of the Grebe application.

By Mr. Owen:

Q. Will you explain what patents issued between 1920 and 1932 which caused the rise in this line on Exhibit 9, and state what those particular patents relate to, that is, just briefly? A. I cannot state the cause which brought on the issuance of these additional patents in that period of time.

The Court:

Well, here is one thing that I see (indicating on the chart): We had just nicely got through with the war and the boom period came on. I do not know whether that means anything in the oil industry, or not.

Mr. Lyon:

It meant a whole lot to the oil industry.

The Court:

You see this upturn here about the time that we got through with the war in 1918, or it may be a little past that.

Witness continuing:

From the point about 1922, where the curve starts to go up, to where it flattens out in 1930 or 1931, very few patents are in consideration in that space. In 1922 the patent issued to Muehl, and that was the sixth application. That is the one at the angle here, right above or just past the 20 mark. The next one was Lake and Phelps, issued in 1924. That is the next point right here (indicating). The next to the right of that, and up a little, is the issuance of Tilton in about 1926. Then the next hump in 1928 is the issuance of the Ranney patent. Then the next is going off to the right, Bowman, 1931. The Muehl patent was dumping acid into a well with a dump bailer to clean out paraffin and calcite deposits and such like. The Lake, et al., patent was for breaking up mud colloids in the well hole. Tilton was for melting out paraffin deposits. Ranney was for melting out paraffin deposits, and Bowman was

for cleaning the well liner. That had not been mentioned previously.

The Court:

Here's the way I understand this graph has been made. Here he starts with the first patent down here (indicating 1865), the next patent he made a date for that, the next patent, and so on; moving up according to the number, getting at the place in the elevation, representing the number of patents, and the date of the application would fix its date for right and left. And then having fixed all those marks, he just hitched them all together. Isn't that the way you made it? A. Yes, sir.

Mr. Lyon:

Yes, but I don't understand this flat one which apparently separates this portion of the curve from that. It seems to me according to the witness' prior testimony there was another additional application between this point (indicating) and this, and necessarily this curve shouldn't show that break, which, in my opinion, unduly emphasizes something that does not exist.

The Court:

What I am going to do right now, instead of spending a lot of time about it, is to ask that they hand you their book of patents and you make one of those graphs.

Mr. Owen:

I am perfectly willing to do that, and have Mr. Rebbeck make his curve.

The Court:

I like things of that kind. There is that continuity. They might easily make a mistake in that.

Mr. Owen:

At the time of the adjournment last evening, Your Honor, we had been discussing the correctness of the chart, Exhibit 9, and I asked Mr. Rebbeck to make a new chart showing where each patent enters the picture, and we have that here, and I would like to have him explain it to you.

The Court:

We will call that Plaintiff's Exhibit 9½.

(The chart was thereupon marked PX-9½.)

The Witness:

This chart, Exhibit 9½, contains the same information that was on the chart we had yesterday, Exhibit 9, with the exception that the curve representing the information is now drawn in a stepwise manner, to bring out the fact that in each of the periods of time involved where there is no change in the number of applications that issued into patents the line of the curve is horizontal. Beginning at the left-hand side of the chart, in the year 1886, the first patent involving the use of an acid in a well was issued, and is shown by this rise here to the level of the first step. Then from that time until about 1872, there were no more applications filed on which patents issued. In that year another one issued, carrying the level up to here (indicating). Then no more applications were filed on which patents issued until 1895, when there were two filed that became patents. That raises the level up to here (indicating). Then from 1895 to 1900, no more were filed until we get to 1900, and then there was a new one filed. That brings the level up to here (indicating). That makes a total of five in those thirty-five years. And then from 1900 to 1920 no application was filed for which we have discovered an issued U. S. patent. Thereupon one more was filed, bringing the number up to 6, and then in about 1922 another one was filed making 7, and then in 1923 or '4, another one was filed making 8. I have put the Carr application in when the continuation was filed and not when the original was filed.

The Court:

You put it in when the continued application was filed, and not when the original one was filed? A. That is correct.

The Court:

If it was put in with the original application, it would come in just over the line somewhere? A. It would come in in 1932, April 28. It would have made this kick up here a little higher, perhaps. It would have made three in here instead of two, as we have it now.

By Mr. Owen:

Q. In other words, if the original Carr application were included it would make this first vertical line to the right of the year indicated by the line 30 a little higher than it is now; is that right? A. Yes, that is right. Now, from 1929 until 1932 there weren't any applications filed on which a patent issued excluding the original of the Carr continuation which is included in this jump. The continuation is included in here and the Grebe-Sanford patent is not included inasmuch as that is one of plaintiff's, but this kick here is due to the filing of the Carr patent, 1,891,667, and a Carr-Humphrey application which issued in 1935, I believe, and I don't recall the number of it. This vertical line at the right of the line indicating the year 1930 includes the Carr continuing application which we have been considering. Even if it was with reference to the original application it would come in the same space. It would just raise this kick up, this step. This little tiny step here would be one notch higher.

The Court:

Now, as he says, as you get higher up you would arrive at the same point all the way up. It just depends whether you cross that road over to the vertical line one notch sooner or not.

By Mr. Owen:

Q. Now, will you continue from the point you left off and state the number of applications indicated in each year by each vertical line? A. Reading from the graph, the first break above the date corresponding to the filing of the Grebe-Sanford represents two more applications on which patents issued, making 12. This step indicates 15 at some date here, I think 1934. The next step indicates about 23 or 22 applications on which patents issued, up to the year 1935. And 25 applications up to 1936. Then we go to that step up here indicating a total of 40. That means there are 28—or there is 30 more than at this time here. And this point is 47, indicating 37 more. And this is 54 indicating 44 more. And that is 56 indicating 46 ap-

plications filed up to this year 1939 on which patents issued involving the use of acid in an oil well.

Q. Referring now to Exhibit 10, please take up the patents indicated under Stream A on the left side of the chart and explain what they disclose. A. On the left-hand side of the chart there have been listed a number of references composed of patents and publications in which some knowledge is given of the use of inhibiting agents to reduce the corrosiveness of acids on iron or steel. The first entry on the list is dated 1845 and is an article appearing in the French publication, Comptes Rendus, by Millon, in which he reports numerous tests made of the corrosiveness of some acid solutions and the effect of the presence in that acid solution of small amounts of metals in the electromotive series on the corrosive action of the acid. This journal apparently has been in publication for many years. I have seen a complete set of them. We have such a set in the Dow Chemical Company's Midland library. I have also seen sets of this journal in other technical libraries, and it is my understanding that it is widely disseminated in the libraries of the world where scientific and other information is kept. I would like to quote a few parts of the translation of this article:

"The impairment of metals either by pure water or by water charged with acid or saline principles is a phenomenon that occurs frequently in the laboratory. This phenomenon also concerns our domestic uses and among industrial facts it certainly has an important place."

The next paragraph goes on to state:

"The experiments that I am about to describe are all connected with this impairment of metals by water in the presence of acids or salts. They only comprise in a word a simple indication of some circumstances under whose action the common metals, iron, zinc, tin, copper are attacked and sometimes preserved but among all these circumstances there is one that I shall point out at once because I think its intervention has been almost unnoticed heretofore. I wish to call attention to the influence of small quantities."

"This influence, if I do not mistake the first impression that I have received, is considerable. If one should say, indeed, that a little quantity of metallic solution, added in the proportion of one thousandth, of one hundred-thousandth, and often in a smaller proportion, was sufficient to increase hundred-fold the action of an acid on a metal, or to annihilate this action, or to provoke it when it did not exist, or finally even to change the nature of the products to such a point that hydrogen replaces nitrous compounds, one would seem to be, in such an assertion, as far from the facts as from chemical predictions.

"Nevertheless, that is what happens."

Those are his introductory remarks, and then he goes on to describe some of these experiments. The method of his experiments, I think, is summarized in this paragraph which I will now quote from page 2 of the translation:

"Thus, rolled zinc has been brought into the presence of dilute sulphuric acid to which has been added some traces either of platinous chloride, or of tartar emetic, arsenious acid, copper sulfate, silver sulfate, etc. The metal, weighed before the reaction, was weighed again after the reaction had lasted for a definite time. In other instances, the gas was collected and measured. I shall indicate the principal conditions of the experiments made by means of zinc and dilute sulphuric acid. The zinc was rolled in sheets thin enough to give 100 to 102 centimeters of surface per weight of 15 grams. The sulphuric acid was composed of one part of monohydrated sulphuric acid SO_3H_2O to 12 parts of distilled water. The zinc was weighed exactly, and six nearly equal quantities of water were introduced into six glass flasks, each of which contained 1½ decilitres of the one-to-twelve sulphuric acid."

The flasks were distinguished by the numbers 1, 2, 3, 4, 5 and 6. Now, I will pass over these experiments on zinc and go to those he performed on iron, inasmuch as we are here interested in iron. Here we have the essentials of his method. He weighs a zinc piece or metal piece and puts it in the acid for a given length of time, withdraws it,

weighs again, and determines by the loss in weight what has happened. Now, the experiments on iron and tin are referred to on page 11 of the translation:

"Iron and tin have been subjected to tests analogous to those of zinc. One-to-twelve sulfuric acid dissolves iron turnings rather rapidly; some drops of platinous chloride communicate an extreme intensity to this action. Arsenious acid, on the contrary, stops all action on iron by sulfuric acid; this influence is sufficiently pronounced for the metallic iron to keep for a whole month, and without doubt still longer, in one-to-twelve sulfuric acid which dissolves it rather rapidly. When the iron is well cleaned, some drops of an aqueous solution of arsenious acid are sufficient to preserve it from the acid; at the same time it preserves metallic reflection whose shade becomes only rather darkened. Tartar emetic slackens the action of sulfuric acid on iron, but does not stop it. Mercurous chloride acts like tartar emetic. Copper sulfate accelerates strongly the evolution of hydrogen; silver sulfate also accelerates it, but less appreciably."

By accelerating the evolution of hydrogen it means that the iron test piece is dissolving at an accelerated rate.

"Hydrochloric acid receives, from small quantities of metals, the same influence as dilute sulfuric acid: these reactions can even be observed with rather concentrated hydrochloric acid; it is sufficient to dilute the pure fuming acid with 2 or 3 volumes of water. In some cases the addition of a small quantity of copper sulfate has suspended very appreciably the action of hydrochloric acid. The iron becomes covered with metallic copper and remains for several hours without furnishing hydrogen; but it has not always been thus, without it being possible to ascertain whether this difference depended on the hydrochloric acid or the iron."

These tests continue with some other acids. The next one mentioned is arsenious acid, and according to Millon arsenious acid stops all reactions as it did with the two preceding acids, the preceding being sulphuric and hydro-

chloric. It goes on to say :"Tartaric and racemic acids are identical in all the influences that they undergo; more abundant evolution with platinous chloride; hindrance to reaction with arsenious acid; almost complete indifference on the part of other metallic solutions." I believe that that gives the essence of this part of the article.

The next reference on the chart on the left-hand side is dated 1883 consisting of a U. S. patent No. 288,150 to Benjamin F. Aiken, Jr., for wire or metal cleaning bath. This, I believe, is one of the first U. S. patents to mention the addition to a corrosive acid of something to obviate its corrosive effects, those corrosive effects being the action of the acid on iron and steel. This patent is in the pickling art, which is briefly stated to be as follows in the patent specification, page 1, column 1:

"In the successive processes of drawing wire the iron becomes fibrous and requires to be annealed to render it ductile and in the operation of annealing its surface becomes more or less covered with an oxide scale which must be removed before the operation of drawing can be continued. This is commonly done by immersing the wire in a hot bath of dilute sulfuric acid for a short time and then checking the action of the acid upon the metal or devitrolizing it by immersing the wire in a bath of hot water or subjecting it to a current of cold water, otherwise the excessive action of the acid bath would render the wire brittle and unfit to be drawn. The wire or wire rods are then coated or covered with a paste of meal or flour, clay or a solution of salt, or of lime, or of a salt and lime, either alone or in connection with oily and fatty substances which act as lubricants to the surface of the wire as it passes through the die plates."

Now, coming to his invention, he says: "I use instead of the bath of dilute sulfuric acid above mentioned a bath formed by adding to water a cleaning corrosive acid. In case the wire is to be drawn I use sulfuric acid; in other cases such as when coating with zinc or tin, hydrochloric or nitro-muriatic acid may be used and to the acid and

water I add cyanogen generally, and for convenience in the form of a metallic cyanide."

Now he goes on to say what he gains by doing that as follows: "By the combination with an acid cleaning bath of cyanogen in the form of a soluble metallic cyanide I increase the efficiency of the acid bath and effect a great saving in the cost of cleaning. I also obviate to a considerable extent the injurious results of the excessive action of the sulfuric acid bath in rendering the iron brittle arising either from the absorption of free hydrogen or from other causes."

The Court:

Is that a very good description of an inhibitant? A. Yes. For the reason that the inhibitants that we find in these patents out of the pickling art are used to correct this hydrogen embrittlement which would otherwise occur if an inhibitant was not used.

Mr. Lyon:

I would just like to have the court have in mind that this is a selection of patents which the defendant in this case has not selected, and it is a different selection from what was before the court in the Williams Brothers case.

Mr. Owen:

I want to make it clear that the purpose of this chart was not to make a complete disclosure of the prior art. We couldn't do it on a chart of this kind. But we merely selected illustrative patents or publications which would show the developments.

Witness continuing:

Now, the next one on the chart, left-hand side, is dated 1901, and is a publication called The Journal of the Society of Chemical Industry in which there appears an article by James T. Conroy on page 316, entitled "The Rate of Dissolution of Iron in Hydrochloric Acid." This article opens with this paragraph:

"The behavior of acids towards metals is a problem of great interest both to the chemist and the manufacturer and such behavior has been the subject of considerable investigation.

"Sometimes, perhaps most frequently, it is the manufacturer's object to obtain a metal not acted upon by some particular acid. At other times, action is desired, and in this case a knowledge of the course of the reaction, its rate and the conditions under which it occurs is of the greatest importance.

"To take a particular instance, I may refer to the cleaning of iron by acids, the so-called pickling process, a preliminary operation in the preparation of this metal for the galvanizing bath."

This article goes on with experiments performed on the rate of dissolution of iron in hydrochloric acid at different temperatures and with different concentrations of acid, hydrochloric acid being capable of many concentrations. Then when we come towards the end, in fact it is the end, he refers to the fact that the foregoing experiments were all done with distilled hydrochloric acid, practically free from impurity of any kind. (Reading):

"In practice commercially pure acid is employed. Such acid must be free from arsenic, the presence of which is prejudicial during the pickling stage apart from the trouble it causes later on in the galvanizing bath. The effect produced when arsenic is present in small quantities is shown in Table 4. When larger quantities are present the iron becomes completely covered with a film of arsenic which at ordinary temperature almost completely checks further action even with the more concentrated acids."

Now, by referring to this table, we see that the experiments were performed with hydrochloric acid of concentrations between 180 and 216 grams per liter, and with amounts of arsenious oxide of from 0.04 grams to 0.16 grams per liter and at temperatures from 18 to 61.5° C. In this experiment he measured the cubic centimeters of hydrogen evolved per hour both before arsenic had been added and after arsenic had been added, and he sets down the rate of evolution figures thus observed. To take one example out of the list, the one that appears on the chart, and converting the concentration given here in grams

per liter into weight per cent we get the following figures:

Two hundred grams per liter of hydrochloric acid is approximately a 20 per cent hydrochloric acid solution. The addition of .16 grams per liter of arsenic trioxide is approximately a 0.015 per cent solution of arsenic, and the rate of hydrogen evolution without the arsenic is given here as 26 cubic centimeters per hour, and when the arsenic is present the rate drops to 19 cubic centimeters per hour or a reduction in the rate of evolution, computed by me to be about 27 per cent.

The next one is dated 1912, an article by Oliver P. Watts, which appeared in the Transactions of the American Electrochemical Society, Volume 21, beginning on page 337, entitled, "The Effect of Various Substances on the Rate of Corrosion of Iron by Sulphuric Acid." The title is a little bit misleading, because he also works with hydrochloric. His opening paragraph is as follows: "In volume 8 of the transactions of this society C. F. Burgess called attention to the remarkable reduction in the corrosion of iron by sulphuric acid brought about by the addition of a small amount of arsenious oxide to the acid." Later he explained the protective action as follows:

"The explanation which has been offered for this phenomenon is that the iron receives by contact with the solution an extremely thin coat of arsenic which resists the action of the acid and protects the underlying metals."

He also gave experimental proof that the iron was coated with arsenic. The second paragraph states:

"It has long been known that by dipping clean iron into solutions of suitable composition and concentration thin coatings of gold, silver, platinum, copper and several other metals may be deposited on the iron. It is generally conceded that such coatings are not sufficiently continuous and impervious to protect the underlying metal from corrosion, even though the metal forming the coating may itself be thoroughly resistant to the corrosive agent. Instead of being a protection, such coatings are usually considered to be stimulators of corrosion."

We started at the place where we had an acid solution containing arsenic in the solution as arsenious chloride, presumably. There is no metallic arsenic in this solution at all. The element is there but it is not present as little bits of metallic arsenic that you could fish out. It is dissolved.

Now, this third paragraph goes on to discuss the theory of this protective action as follows: "Since all metals which thus deposit upon iron when it is immersed in a solution of the metallic salt are electro-negative to iron, a short-circuited voltaic cell is formed, of which the iron is anode and the metal deposit is the cathode. So long as any iron remains in contact with the electrolyte, it would seem, except for certain considerations which will be presented later, that the corrosion of the iron ought to be stimulated by this condition, and that the only way in which such a coating could afford good protection would be by covering the iron completely, so that no electrolyte could come in contact with it.

"Speaking of the effect of other metals in contact with iron, W. H. Walker says: 'Tin is a metal which, like copper, accelerates the corrosion of iron by aiding in the oxidation of the hydrogen set free by the reaction.' M. P. Wood calls attention to the injurious action of metals, 'The use of anti-corrosive, or anti-fouling paints, containing salts of any metal, is attended with the greatest danger to the coated (iron or steel) structure. These pigments are extremely sensitive to the presence of saline elements in moisture, their action being to rapidly dissolve portions of the iron, and to deposit the metal which they contain upon the surface of the plates, and these deposits, exciting energetic galvanic action, cause corrosion and pitting to go on with alarming rapidity. Both mercury and copper salts are offenders in this way.' "

I am going to read directly from paragraph 2 on page 338. (Reading): "It appears then, that arsenic is unique among the metals which precipitate themselves upon iron from solution, for arsenic protects iron almost completely

from powerful corrosive agents, while the other metals are generally considered to aggravate corrosion and rusting.

"If the coating of arsenic is so porous and imperfect as the action of acids show the coating of copper, for example, to be, how can the arsenic protect the iron any better than copper does? It occurred to the writer that the explanation lay in a high over-voltage or excess potential of hydrogen on arsenic, and the experiments which follow were undertaken to discover whether this is the explanation of the singular and mysterious protective action of arsenic. If the above explanation is correct, among the metals which deposit upon iron when it is immersed in a solution of their salts those having a high over-voltage for hydrogen should protect iron, and those of very low over-voltage should aggravate the corrosion."

The Court:

Does that mean that silver and copper, and those other things that he mentions actually tend to corrode, destroy iron when they are present, worse than if they are not present? A. Yes.

The article goes into the matter of the electrode potentials of the metals involved here, that is the voltage assumed by the metal with respect to the solution in which it is immersed, and he gives a table of what is called single potentials of many of the metals in the electromotive force series of metals between iron and mercury, and including those metals. Then he goes on with his theory as follows:

"On the theory that the protection of iron by a deposit of arsenic is due to the high overvoltage of hydrogen on the latter, the action would be as follows: Iron dissolves and by so doing deposits arsenic upon the surface of the iron. Since the arsenic is deposited simultaneously with the dissolving of the iron and only as a result of this dissolving it is hardly possible that the iron should be completely covered by arsenic, but here and there holes will exist allowing the iron to make contact with the electrolyte. Voltaic cells are thus formed."

The Court:

Is this chap right in his theory? A. I subscribe to this theory. (Continuing reading): "The iron is anode and the arsenic cathode, and just as in any other primary cell with sulfuric acid as electrolyte, hydrogen is deposited on the cathode, but when hydrogen is liberated on arsenic the potential of the latter is raised 0.39 volts higher than 0.277, the potential at which hydrogen is liberated on platinum black. This would raise the potential of the arsenic to +0.113 volts or higher than the potential of the iron anode. This means that in our iron-arsenic cell there can be no visible evolution of hydrogen on the arsenic for before this can occur the potential of the cathode has become equal to that of the anode and corrosion of the iron ceases. In other words, this particular primary cell polarizes so badly that after a few seconds of action its electromotive force has fallen to zero."

Then he goes on to say (reading): "If the above explanation is correct, protection should be afforded by those metals which plate out on iron by immersion, and whose over-voltage for hydrogen is great enough to raise their potentials to at least equal the single potential of iron. The potentials of the following metals are far enough below that of iron to expect that they will deposit on iron even in moderately strong sulphuric acid."

By Mr. Owen:

Q. In this Watts article, I notice that on page 352 he gives a table under several headings: One of them is "Retarders of Corrosion," and another on page 352 is "Accelerators of Corrosion." Now, I would like to have you state to the court which metals are contained under each of these headings, first under the heading of "Retarders of Corrosion." A. The first here is arsenate of sodium. Of course, that is not a metal but it is a compound containing the metal which he used. Arsenic sulphate, chloride of manganese, chloride of mercury, chloride of sodium, chloride of tin, chrome alum, chromium sulphate, mercuric chloride, mercuric sulphate, and stannate of sodium. Stannate of sodium is a tin compound.

Under the heading "Accelerators of Corrosion" the first in order is bismuth sulphate. Then chromium chloride, copper sulphate, gold chloride, mercurous nitrate, platinum chloride, potassium chlorate, chromate, dichromate, nitrate, permanganate.

The next reference on the chart, Exhibit 10, is a publication from the Bureau of Mines, Department of the Interior, dated October, 1919, entitled "Substitution of Nitre Cake for Sulphuric Acid in Pickling Steel," by E. E. Corbett, Chemical Engineer, U. S. Bureau of Mines.

On page 2, under the heading of "Mechanism of Pickling Reactions," it states (reading): "The free acid in hot, dilute solution attacks the metal very readily, etching it away from beneath the coating of scale and consequently throwing off the particles of oxide from the surface. Iron goes into solution as ferrous sulphate; and the hydrogen which is liberated at the face of the metal is carried rapidly to the surface of the solution, where it escapes into the air with the steam and other gases rising from the pickling bath. * * *"

Now, the portion of this publication which is of interest in this connection here is that part beginning on page 5 under the heading of: "Inhibition, or moderation of metal attack," as follows:

"The activity of the acid, then, is directed to attacking selectively and dissolving the sound metal rather than the more resistant oxide or scale; but in well regulated pickling practice the selective attack is limited, and, indeed, materially re-directed and controlled by the use of bodies of a colloidal or semi-colloidal nature whose influence serves to protect the metal during scale removal. These bodies are for the most part of vegetable origin, and comprise various wood sugars and gums, and cereal starches and intermediates occurring in commercial grain milling."

And then he goes on to mention other types of inhibiting agents as follows: "Tin and copper salts are representatives of the inorganic type of semi-colloidal inhibitors; but their action is of inferior consequence and their use re-

stricted because of the cost of adding to the bath quantities sufficiently large to exercise a sensible influence, as well as their tendency, undesirable for most purposes, to plate out from solution upon the metallic surface."

Mr. Lyon:

I would like to ask a question before we leave this Corbett article. Was this article ever published? If so, where, or from where, by whom, and when? A. I can refer to an article which appeared subsequently to this as a result of the issuance of this article by Mr. Corbett in the Automotive Industries for 1918, December 5. This article was almost re-written word for word in that publication, which, of course, has wide circulation in the metal trades.

The next reference under Stream A of Exhibit 10 is dated 1921. It is the British patent No. 158,768, having a complete accepted date of February 17, 1921, for improvements in pickling iron or steel. This patent is apparently the counterpart, or the British application corresponding in many particulars to one filed in this country in the name of Vogel, so I have put the name Vogel against this British patent. This teaches about the corrosive action of the acid during the pickling operation, and some of the evil effects resulting from that, and proposes the addition to the pickling bath of certain substances to overcome those difficulties.

Quoting from the specification, page 2, column 2, beginning with line 73, it reads as follows:

"A modification of the process consists in adding to the pickling liquor, not the protective substance itself but a suitable extract thereof. It has been found that it is not the main constituent of the substance in question, namely, anthracene, naphthalene, phenol or the like, that has a particularly good effect, but other constituents the chemical constitution of which has not been elucidated, but which nearly always accompany the main constituent. The active substance may be extracted by inorganic acids, neutral or acid salts, organic solvents such as hydrocarbons (petroleum, tar oil). Advantageously the parent substance may

be treated with 3 to 4 parts of sulphuric acid of strength which may vary, or of hydrochloric acid or of other suitable extracting agent and, according to its strength, 1 to 10 per cent of the extract may be added to the pickling liquor.

"There is added to the liquor a quite small proportion of a material which causes formation of the thin protective layer. For forming such a layer, having regard to sufficiency of supply and cost, the following has been proved particularly suitable additions:—Crude anthracene, sulphite lye, residues from the production of naphthalene and the like."

There are some other substances mentioned which might be used. "There may also be used either alone or in addition to the said parent substance the waste acid from the refining of mineral oil, ground coal tar oil, coal tar oil, paraffin wax, and the like, or acid resins, or distillation residues of organic compounds of any kind, particularly residues in which pyrogenis decomposition has occurred." By Mr. Owen:

Q. In this British patent, is mention made of any particular acid in which these inhibiting substances may be used in connection with the pickling bath? A. There is the mention of a dilute mineral acid, for instance hydrochloric acid of 22 Baume specific gravity used, or sulphuric acid of 10 to 12 Baume specific gravity, frequently mixed with a solution of sodium sulphate.

The last patent is dated 1928, No. 1,678,775, to James H. Gravell. This patent discloses the use of metals in an acid solution, the same metals that we have previously seen and which have been referred to in some of these prior articles, including the Watt article, for the purpose of putting a protective coating on iron and steel containers, so that the action of the acid on the containers would be prevented. And these metallic inhibitors may be used in that process with and without the presence of what are here called pickling control substances or acid regulators.

The acids which are supposed to be rendered non-corrosive by the presence of these added metallic elements are

any of those acids commonly or normally corrosive to iron or steel, and because of that corrosiveness would have to be carried in glass or specially lined containers.

Q. According to this patent, what metals are supposed to have that protective action? A. The patentee states that "The metals which have that property are below iron and above mercury in the electro-motive scale." Some of the common metals that lie in that range of the series are cadmium, nickel, lead, tin, arsenic, antimony, bismuth, thallium and copper.

CROSS EXAMINATION

By Mr. Lyon:

Q. In connection with the selection of those patents didn't anybody suggest or refer to the list of patents appearing at the bottom of page 496 of 81 Federal Reporter, Second Series, the particular patents that were referred to by Judge McDermott as showing inhibitors? A. I don't recall whether they looked at that or not.

Q. You didn't hear any discussion about whether you better put on this Stream A the same patents that Judge McDermott set forth in his opinion, or whether you better put different ones in? A. I do not recall anything like that. I am practically certain there was no mention of that.

Q. What is supposed to be represented here by the graphical illustration extending from Gravell's patent in 1928 down to this block in which appears the words "Grebe and Sanford"? That there are no patents between the Gravell patent and Grebe and Sanford's patent relating to the addition of inhibitors to hydrochloric acid? A. No, it doesn't mean that. I don't recall what ones intervene in that period. I don't remember how many there were in that thing. It seems to me there were quite a number of patents in this art of pickling and its related arts, but their pertinency—it doesn't add anything to these things that are already there such as there were where,—I believe they were left off for that reason.

In my search of the prior art and the investigation that I made of patents and the literature references prior to the Gravell patent, I found reference to shipping hydrochloric acid in a steel container or drum, protecting the drum or container by the use of an inhibitor. Those references are not on this chart. These are simply in connection with the prior state of the art for Grebe and Sanford.

There is a reference by an author named Fawcett in the Journal of the Society of Chemical Industry of London in which he discloses the use of arsenic to be added to sulphuric acid and for the shipping of that acid in an iron drum so that the drum would not be attacked. This article is entitled "Action of Concentrated Sulphuric Acid on Iron."

Q. Did you find anything in this Fawcett article that refers to shipping hydrochloric acid in steel containers? A. I don't believe there is mention of that.

Q. Well, now, have you found any other, is there any reference that you have found that you have omitted from Stream A prior to the Gravell patent which suggests shipping hydrochloric acid in a steel container and protecting the container by an inhibitor? A. I believe there is another one. The patent to which I refer is No. 1,608,622, filed September 30, 1925, for process for preventing the dissolution of iron and steel in sulphuric acid and pickling baths.

Q. In connection with arranging your curve on Exhibit 9-A, we discussed the Carr patent. I hand you a certified copy of the file wrapper of the Carr patent as it issued, No. 1,891,667, and the parent application filed April 28, 1932. Have you ever read either the original application or the Carr application, upon which the Carr patent was issued? A. I may have, but I have forgotten now.

Mr. Lyon:

I would like to offer, Your Honor, so that we can have it for future discussion, these two certified file wrappers; the first being the file wrapper upon which the patent was issued, No. 1,891,667; and the second, the file wrapper of the earlier application.

The Court:

Let us call the first one that you marked DX-11, and the other will be DX-11½.

(The documents in question were thereupon marked Exhibits DX-11 and 11½.)

Q. Now, who made the decision in connection with what was to be incorporated on the curve of Exhibit 9-A, that this Carr patent should not go on the curve, or, should not go on until after you have indicated that the Grebe and Sanford invention had come into existence? A. I decided that.

Q. Who? A. I decided that.

Q. Did you discuss that with counsel for the plaintiff here, who are appearing in this case? A. Yes, I discussed that.

Q. On what basis did you make that decision? A. Let me see. The decision to put these patents on was based upon the filing dates, and I assumed that that would fairly represent the date of invention of these patents, in the absence of other knowledge on the subject.

Q. Then you did not actually go into the question, the factual question of which of these inventions was earlier? A. That is right. I am not advised as to that.

Q. You know, do you not, that the Dow Company, the plaintiff in this case, holds the rights under this Carr patent, and the invention of Mr. Carr? A. I do not know what you mean by that.

Q. You don't know what I mean by that? Don't you know that the Dow Company is licensed under this Carr patent and Carr invention? A. Yes; they have a license.

Q. You know that the Dow Company pays a $5.00 royalty for each and every acidizing job that it does to Pure Oil Company under these patents, do you not? A. That is what I have been told.

Q. Well, now, you did not go in to find out whether the Carr invention was ahead of the Grebe and Sanford invention? A. Not in constructing this chart, no.

Q. Did you have anything to do with the preparation

of the application upon which the Grebe and Sanford patent No. 1,877,504 was issued? A. No.

Q. That was not any—you did not have anything to do with that? A. No, I did not.

Q. You don't know whether or not as originally prepared that application prescribed that the use of inhibiting acid was unnecessary, or the use of an inhibitor in the acid was unnecessary? A. I had no part in the preparation of that application.

By Mr. Lyon:

Q. Referring now to this Exhibit 9-A, the curve, can you give us a list of the patents and other references that are embodied in this curve subsequent to the point on the curve to which the arrow refers, and with a statement as to what they are about? A. The Carr patent 1,891,867 filed June 30, 1932, was a method for facilitating the flow of wells and, briefly, it consists in loading the well hole with oil so as to confine the acid subsequently introduced to the lower levels of the well to prevent the acid from rising in the casing.

DeGroote, 1,922,154, filed January 9, 1933, proposes to emulsify acid in an encasement of oil before putting it in the well so that it won't corrode the pipe.

MacMillan, 1,969,230, filed February, 1933, loads the well with oil to force the acid into the producing formation.

Weir et al, 1,984,668, filed March 10, 1934, is for demudding the walls of the well hole with acid when the mud has previously been treated with calcium carbonate so it will have an acid soluble constituent in it.

Wilson, 1,990,969, filed March, 1933, is for acidizing an oil producing formation, the acid for the purpose being generated in situ by the reaction of a solution of hydrochloric acid and a soluble fluoride.

Ambrose et al., 1,999,146, filed June, 1934, for a method of increasing the production of wells proposes to employ chlorine gas in the well hole, the gas reacting with water therein to generate an acid.

Mills, 2,001,350, filed 1934, proposes to introduce into

the well and into the producing formation in succession alkali, then an oil spacer, then acid, and repeating that over and over, thereby forcing out into the surrounding formation concentric rings of acid and alkali which eventually mingle with each other and generate heat in the formation, or otherwise do something there.

Muscatt 2,010,409, filed 1934, is for producing a plugging deposit in water-bearing formations, which might be adjacent to the oil producing formation or even in the same formation, and he reacts therein sulphurous acid and hydrogen sulphide, thereby getting a precipitate of sulphur in the pores.

Carr, et al., 2,018,199, filed October, 1932, is for balanced pressure method for introducing acid reagents into oil wells and it consists in introducing inhibited acid, that is, acid containing arsenic acid, into the oil well after it has been allowed to fill with the produced fluid of the well.

Muscatt, 2,016,118, filed 1935, is for method of selective shutting off of water flow in oil wells, and consists in injecting sulphur mono-chloride into the well under heavy pressure so that it enters and passes outward through the pores of the wet formations, the sulphur mono-chloride hydrolyzes in the earth formation, thereby depositing free sulphur, and, of course, along with that reaction there is produced hydrochloric acid.

Woods, 2,030,777, copy of which I do not have here, is about drilling a well in an acid-soluble formation with conventional rotary tools, and in place of circulating drilling mud through the tools while the drill is in operation, he would use hydrochloric acid.

Pitzer, 2,035,719, filed in 1935, is for method of treating oil and gas wells and he proposes to introduce into the cavity at the base of the well what he calls an inert crushed treatment material of a particular size or mesh, namely 1 to 1½" mesh, and he may thereupon treat the well with acid or alkalis or other chemicals.

DeGroote, 2,038,720, filed 1936, is for process for increasing productivity of wells and it consists in emulsify-

ing two different reagents, introducing them into the well and allowing these emulsions to mingle and produce a reactive agent in the well, which is forced into the formation.

Parkhurst, 2,038,956, assigned to the Standard Oil Company, filed in 1934, is for the acid treatment of an oil well, the title being "Well Treating," and it consists in introducing the acid solution into the well and then a charge of an aqueous solution of caustic soda.

DeGroote, assigned to Tretolite Company "Process for Increasing the Productivity of Wells," No. 2,045,759, is similar to the other ones where he employs an emulsified acid for acid treating in the producing formation.

Davis, 2,045,899, filed April, 1935, is for method of increasing production from wells, and it discloses to use acetic acid for the purpose, the acid being injected into the producing formation.

Saukatis, filed 1934, 2,049,517, discloses to treat wells by introducing into them an inhibited acid solution, the inhibiting agent being a combination of copper and any one of dozens of organic chemicals which themselves have an inhibiting action.

DeGroote, 2,050,931, filed 1936, is for "Preliminary procedure for conditioning wells," after which he discloses that they may be treated with hydrochloric acid.

DeGroote, 2,050,932, filed in 1936, employs an emulsified acid solution for treating the well, there being present what he calls a dormant de-emulsifier so that this emulsion will not break too soon.

DeGroote, 2,050,933, filed February, 1936, refers to his earlier patents on the use of an acid in an oil well, and this one is for a modification of that type of process employing an emulsified hydrochloric acid as the treating medium.

Hund, et al., 2,059,459, filed June, 1936, proposes to employ a non-aqueous acid solution, the acid becoming active upon dilution with water in the producing formation.

Pitzer, 2,080,875, filed March, 1936, for method of and means of treating wells, discloses the idea of exploding a cartridge in the well bore beside the producing formation,

the cartridge walls being loaded with projectiles, and the container cartridge may also contain chemicals, and when this cartridge explodes, it forces these projectiles and the acids, or whatever it is, in the container, into the side walls of the well hole.

Vandergriff, 2,094,479, filed December, 1936, for treatment of wells, consists in injecting into the producing formation a mixed acid solution containing hydrochloric acid and hydrofluoric acid.

Lang, 2,107,007, filed in 1936, discloses in connection with a process entitled "Method for increasing the recovery from oil sands," the use of an acid solution for increasing the permeability of the formation surrounding an input well; that is a well, I understand, that is used for repressuring operations. The particular feature about this process is the mechanical treatment of the well bore before the acid is used.

Clason, 2,122,452, filed 1936, is for acid treatment of wells wherein he has a special way of blanketing off certain formations with a blanketing medium and acidizing the other portions.

Menaui, 2,122,483, filed January 11, 1937, is for "method and means for acidizing wells" wherein there is first put into the well hole what he calls a non-jellifying material in admixture with calcium chloride solution ahead of the acid.

Miller, 2,124,495, filed April, 1936, is for treatment of drilled holes and consists in using hydrochloric acid to de mud well hole when the mud contains calcium carbonate. It is distinguished, however, from that Weir et al. patent previously mentioned by me in that in this case the carbonate used is a solid powdered form, whereas in the Weir et al. it might be an aqueous solution of the carbonate. I believe I might have wrongly stated the nature of the carbonate used in that Weir et al. patent as being solid, and I think it is really a solution that is used.

Loomis et al., 2,124,530, assigned to Shell Development Company, filed 1936, is for "method of treating wells," and

it makes use of water insoluble organic solvents in combination with aqueous acids.

Morgan, 2,128,160, filed 1937, is for well treating fluid consisting of an acid solution containing gelatin or what he calls a protective colloid capable of maintaining the mud present in an oil well in a suspended and dispersed condition in the presence of strong acids.

Morgan, 2,128,161, filed July, 1938, is for well treating fluid, this fluid consisting of an acid solution containing what he calls a calcium sequestering agent.

Bresler, 2,140,183, filed July, 1936, is for method of treating wells, and he uses an acid solution containing barium chloride.

Savits, 2,143,251, filed June 1938, is for method of and equipment for acidizing wells, and discloses a special device in combination with a packer and tube for acidizing independently more than one formation in the same well.

Averson, 2,148,006, assigned to Standard Oil Company, filed October, 1938, is for acidizing a well with sulfamic acid.

Menaul, 2,149,617, filed December, 1936, is for method and apparatus for handling acidic solutions and it discloses that by electrically coupling metallic lead to the tubing of an oil well through which acid is to pass in acidizing the well the tubing will be protected from corrosion.

Owsley, 2,163,449, filed 1938, is for method of treating a well. The use of acid in connection with this has to do with opening up a water stratum into which cement is to be injected so that the cement will enter. Thereafter the water will be shut off, as I understand that.

Lee, 2,171,416, for method of treating a producing formation involves the making of superimposed lateral channels from a well hole and acidizing these channels independently.

Herbsman, 2,172,083, is for method of treating inorganic mineral slimes in oil wells, filed May, 1937, which comprises forming an aqueous suspension of a sulfonated glyceride and introducing the suspension into that portion

of a well in which there are accumulations of slime. The specification states that in treating a slime of the carbonate type, the treating agent is produced by forming a suspension of sulfonated glyceride with an aqueous acid solution. The acids usually used in this solution are hydrochloric acid or acetic acid.

Loomis, et al., 2,177,345, assigned to the Shell Development Company, filed 1938, is for method of treating wells. This consists in employing an acid solution to which acetone has been added, or the like.

Simmons, 2,186,349, filed January, 1937, is for method of acidizing wells, the feature about this being mechanical means and methods for locating the acid where desired in the well hole.

Pitzer reissue 21,356, application for reissue February, 1938. This discloses the same invention as in the previous Pitzer patent, bearing original number 2,080,865.

Robinson, Jr., assigned to the Texas Company, 2,198,563, filed June, 1937. In connection with his process, called "Method of Completing Wells," in which a drilling mud fluid may be used as the circulating medium, and may contain calcium carbonate, he employs an acid solution for disintegrating the mud after the well has been drilled.

DeGroote, 2,204,580, application February 17, 1936, assigned to The Dow Chemical Company, is for acidizing a well with an acid solution containing a preferential wetting agent comprising an alkylated sulpho-aromatic acid.

Herbsman, 2,206,187, filed June, 1937, for "Method of Increasing Production of Oil Wells," consists in introducing a solution of hydrochloric acid gas absorbed in a liquid, which is immiscible with water in the well, a liquid such as oil.

Holmes, 2,224,297, filed April, 1939, for treatment of oil wells, consists in employing a strong acid with salts.

Carr, 2,237,131, assigned to Pure Oil Company, filed December, 1938, for treatment of wells, consists in a process of drilling involving the use of an acid solution not as an aid to the drilling but in certain stages of the drilling,

for the purpose of increasing the porosity of the formations being drilled.

Zacher, 2,234,790, filed February, 1939, for mud wall disintegrator, discloses the use of a weak acid to which a salt of a strong acid has been added for cleaning off the mud from the walls of a well hole.

Mr. Owen:

I would like to ask a question now. In this list of patents you have just read I notice that at least one patent was included which was assigned to The Dow Chemical Company. Will you explain again, in that connection, just what it is you have omitted from that graph with reference to Dow Chemical Company inventions? A. I omitted applications that were of Dow inventors, but I included that DeGroote application, although it was owned by Dow, but we didn't come to own it until some time after it had been filed in the Patent Office.

Q. So that this list does not include any inventions or any patent to inventors who were employees of The Dow Chemical Company subsequent to the Grebe and Sanford patent? A. Yes, sir.

Q. Were any Dow applications omitted which were filed prior to the application for the Grebe and Sanford patent? A. Yes.

Q. Then this graph does not include any patents issued on applications of Dow Company inventors other than the Grebe-Sanford? A. It does not include that one. I haven't included any Dow inventors' applications on which a patent issued.

Q. Then the Grebe-Sanford application on the chart and the arrow pointing to one of the angles is merely to indicate the point where the Grebe-Sanford application would have come had it been included? A. That is correct.

Q. Could you state how many applications filed by Dow Company inventors there are which would have been properly included in this chart had you wanted to make it complete so as to cover all applications? A. The number of applications which have now matured into patents,

the same as the ones I have spoken of, except for ownership, I think there are 28, or thereabouts.

By Mr. Lyon:

Q. This list that you read in answer to my previous question, of the patent applications that are embodied in the curve Exhibit 9½, subsequent to 1932, included many relating to inventions that were not actually on acidizing wells; they relate to various other inventions which involve in some way the use of acid down a well, rather than acidizing inventions? A. That is correct.

Mr. Owen:

That applies also to the part of the chart previous to Grebe and Sanford? A. Yes.

By Mr. Lyon:

Q. Now, it will only take a minute just to complete this information about this curve, if you have it there, so I am going to ask you to identify the particular patents that are responsible for these steps on the curve prior to 1932. You have done that partially, but in looking through the record, I could not make it add up. A. The first kick up is due to the Sherwood patent, No. 57,982, and in that connection I should state that I have assumed that the issue date of Sherwood is the same as the filing date because I did not have any means to determine the date on which it was filed. It does not appear on the copy of the patent. Then the next kick up is due to the addition to that of the Looney patent application, which became patent No. 139,010. The next is due to the two patents issued on applications filed in 1895, the first is Van Dyke, 556,651, and the second Frasch, 556,669. The next rise is due to the Ball patent application which matured into patent 670,577. The next is Muehl, filed in 1920, and issued into 1,410,827. The next is Tilton filed in 1922 issued into 1,608,869. The next is Lake and Phelps, filed 1923, becoming patent No. 1,498,045. The next is Ranney filed 1928, issued as 1,806,499, and the next is Bowman, filed 1929, and issued as 1,809,546.

I did not embody or include in my curve the patent to DeGroote, 1,892,205, of December 27, 1932. I am not especially familiar with that patent.

Q. Well, I think if you look at it you can see quite quickly that it relates to a solution which is put down an oil well to prevent the accumulation of solid matter, and it gives a review of the prior patents of the Tretolite Company on that same subject. They are listed on page 2, the patent to Brady and the patent to Campbell. Are you familiar with those patents? A. I have seen those patent copies, I am pretty sure.

Q. Well, will you tell me why those are not properly included within the list of solvents, chemical solvents employed to aid in a producing well? A. I would have to take a look at that again, but my collections from which this is drawn have been classified to include such patents as involve the use of acid in a well, and since I did not find any others in my group I haven't put them on the chart. I therefore have assumed that my chart completely represents patents that involve the use of an acid, and that these therefore did not.

I considered in connection with the preparation of my charts the Ackerman patent 1,734,990, granted November 12, 1929, and I hand you a copy of that. It mentions sulfuric acid, but it doesn't come under my classification. It discloses a composition of matter which, as Mr. Lyon states, is for the purpose of preventing pipe lines from becoming clogged, and this composition of matter is made up of the following ingredients: Anthracene, 3¼ per cent, sulphuric acid, concentrated—that is 93 per cent concentrated—0.65 per cent, oil of mirbane, or nitrobenzene, 1.3 per cent, naphthalene flake, 66 per cent, sodium hydroxide granular or powder, 28.8 per cent. Upon forming this composition of matter, the sulphuric acid originally present becomes sodium sulphate and the mixture is no longer an acid solution and it, therefore, does not comes under this classification.

I am familiar with the patent to Walker, No. 1,873,083, granted August 23rd, 1932, on an application filed October 30th, 1926, and have it in my collection and have read it. It is my recollection about this that it does not disclose putting acid into a well. Perhaps I have overlooked it, but that was my recollection.

By Mr. Lyon:

Q. The patent refers, does it not, to a method of treating oil wells by lowering fluid, for introducing a fluid into the well to remove scale (handing patent to witness). I think that is what the patent is about. A. The first claim in the patent reads as follows:

"The method of treating oil well liquids to render them non-corrosive and non-scale forming which comprises adding to the well liquids a reagent comprising mixture of an alkali metal salt and a caustic alkali solution of tannin in amounts sufficient to cause precipitation of the insoluble alkaline earth salts upon the well liquids in a pulverulent and non-scale building form."

That, of course, is not an acid solution. It refers to a number of acid substances, but, of course, they are not used as such in this process. It used salts of those acids rather than the acids themselves, and I excluded the patent on that understanding.

I have seen patent 1,804,078 granted to Martin William Baden of Winfield, Kansas, on May 5, 1931, on an application filed November 26, 1928. It was not considered by me at the time I compounded the data for that curve.

Mr. Owen:

I offer books of patents in connection with Charts 9, 9½ and 10. Call the book with reference to 9 and 9½, PX-9¾, and the one with reference to 10 call it PX-10½.

DONALD D. HALL,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I reside at Midland, Michigan, and am superintendent of the Chlor-benzol plant for The Dow Chemical Company. I have worked for The Dow Chemical Company since 1923.

I am a chemical engineer, graduating from Case School of Applied Science in 1921, and I worked in the intervening time for The Standard Oil Company in Cleveland, Ohio. When I first was employed by The Dow Chemical Company I worked in the salicylates division, doing laboratory work on pharmaceutical products. It is aspirin and those products. Thereafter the Chlor-benzol plant was started up and we did some laboratory work as this plant was being started, and I worked into the superintendency of that particular plant. The primary product of that plant is monochlor-benzol. Hydrochloric acid is a by-product. There is considerable use within the Dow plant for hydrochloric acid, and that took care of quite a large part of it, and about 1931 we began to ship it to customer accounts. We had only a few customers to begin with and first we only had one car, a rubber-lined tank car, 8,000 gallons, in which we shipped the acid; then it gradually developed from that point. The hydrochloric acid is manufactured in standard commercial strengths of 18 Baume, 20 Baume, 22 Baume, and recently we have a stronger acid. Prior to 1932 we shipped it in standard commercial strengths. As this acidizing of wells developed we began to supply that acid in 15% strength.

I have our record of shipments of hydrochloric acid for the year 1932 with me. The first shipment I find in our record reads as follows, it is the second shipment of the month, dated February 11, Order No. 38,118, to the Pure Oil Company of Mt. Pleasant, Michigan, of one wagon of

15 per cent HCl, 790 pounds 100 per cent HCl. That was on February 11, 1932. I don't know what particular well that went to.

By Mr. Owen:

Q. Was anything placed in that 15 per cent acid before it was shipped on the occasion to which you have referred?

Mr. Lyon:

Well, I don't think the witness has laid any foundation for that answer. As far as I know he has only identified this book. He hasn't stated that he manufactured the acid or remembers the transaction. Maybe he does, but I think your foundation should be laid.

Mr. Owen:

He stated he was in charge of the Chlor-benzol plant of the Dow Chemical Company.

The Court:

I will let him answer. You can cross examine him and see how far wrong he has gone in saying he knows. I will let him answer. A. Yes. We secured arsenic acid. We obtained that in a two gallon glass bottle from the lead arsenate plant and put it in that shipment. That is another plant within the Dow organization. I personally know that that two gallons of arsenic acid was placed in this 500 gallon shipment of 15 per cent hydrochloric acid. I did not do it myself, but I secured the acid. I had to use the telephone to secure the arsenic acid and have it delivered and gave the orders to the men to put it in. I can't say that I saw it put in but I am satisfied it went in that shipment.

The Court:

Did you put it in so it wouldn't eat up the tank that carried it? That is the purpose of it? A. Yes. I presume that is the purpose.

Mr. Owen:

Q. Do you recall what kind of a tank that acid was placed in at your plant? A. I think that first one was a wooden tank wagon that was placed on a truck; rather, this whole thing was gotten together rather hurriedly in order to get it to the field as quickly as possible.

The Court:

Then, it wouldn't be for the protection of the tank?

Mr. Owen:

No, it would not. It was for the protection of the tubing in the well.

The Court:

In the well?

Mr. Owen:

Yes.

The next shipment I find in my record of 15 per cent hydrochloric acid was made March 11, 1932. It was virtually a duplication of the previous shipment, 500 gallons of 15 per cent acid. Two gallons of arsenic acid. The next shipment was on April 5, 1932. That was 15 per cent acid with the two gallons of arsenic acid. 500 gallons of acid. And the next shipment was April 27th. Those were all in the same amount. Each shipment contained two gallons of arsenic acid. Those shipments were all made to the Pure Oil Company. Other shipments were made to the Pure Oil Company on May 5th, 21st, 25th, 27th, 28th, and 31st. Those shipments all were the same as the previous ones, 500 gallons of the 15 per cent hydrochloric acid, and containing 2 gallons of arsenic acid. In the first half of June there were about eight shipments, that is, June 1, 3, 4—there were two on the 4th—on the 7th, 9th, 11th, 13th and 15th. Those were all of the same amounts of acid and in each case the acid contained the two gallons of arsenic acid. Four of those were made to the Pure Oil Company, and four to miscellaneous other companies, three to the Columbia Oil & Gas Company, and two to Lawrence Lee.

The Court:

Can you give me some idea as to how much of this was used in acidizing a well? A. Well, they would sometimes come in for a second load to put in the same well. I think originally they only used about one 500-gallon treatment, but later on they began ordering larger amounts. I cannot answer as to the practice in the field.

The Court:

But you think they used at least the one 500-gallon tank in a well?

Mr. Owen:

That is the fact, Your Honor; and now the treatments run up, I understand, as high as 10,000 gallons for one treatment. They started in with 500 gallon treatments.

The Witness:

During the last half of June, 1932, there were 23 shipments of this 15 per cent hydrochloric acid, part of them to the Pure Oil Company, and the others to miscellaneous users. Others than the Pure Oil Company receiving those shipments were The Chippewa Oil & Gas Company, the Mt. Pleasant Oil & Gas Company, W. L. McClanahan, Lawrence Lee, the Talbot Oil Company, the Gordon Oil Company, the Storkwell Oil Company, the Michigan Gas & Oil Company, the Luther Drilling Company and Ohio Producers & Refining Company, the balance being for the Pure Oil Company. Some of those shipments were for 1,000 gallons instead of 500 gallons. In the thousand gallon shipments, four gallons of arsenic acid were put in.

During July, 1932, 51 shipments of this 15 per cent acid were made. Those were either for 500 gallons or 1000 gallons of this 15 per cent hydrochloric acid, with the proportionate amount of arsenic acid.

Q. Will you name the different companies or individuals to whom those shipments were made during July, 1932?

Mr. Lyon:

I might suggest if counsel had some kind of a schedule of this, or table of it, or some summary, we don't contest the shipments at that date after the filing of this application, and you can put it in much quicker than calling the witness.

Mr. Owen:

We have such a summary made up which the witness is testifying from.

The Court:

You can call it an exhibit, and I will admit it.

Mr. Owen:

I will offer that summary, then. It goes up to and including November 10, 1932, which was the date when Dowell, Incorporated, was organized and took over the business.

Mr. Lyon:

You say it is a correct summary, or if you say the witness will testify it is a correct summary, why, we will receive it as such without any argument about it, Your Honor.

Mr. Owen:

We will ask the witness about this.

By Mr. Owen, continuing:

Q. Is this a correct summary of the entries in your original book of entries for that period? A. It is essentially correct. There may be one minor typographical error, of which I am not familiar.

Q. At least you haven't put any entries on this summary that are not in the book? A. To the best of my knowledge it is correct.

Mr. Owen:

I will offer that as Exhibit 12.

(The summary above referred to was thereupon marked PX-12.)

CROSS-EXAMINATION

The order number for this shipment which was made on February 11, 1932, and which I state was the first shipment of 15 per cent hydrochloric acid made by the Dow Company was No. 38118. The shipment record reads: "Product: Hydrochloric acid. Month of February, 1932," and shows only seven orders during that month. It was the only one of those orders showing 15 per cent hydrochloric acid. Independent, down below all these entries, is written in there 2 gals. arsenic, Pure Oil. Relative to the making of these seven entries, that was put on there at the same time or at the end of the month. In a later case, we had a trans-

fer between the lead arsenic plant and the Chlor-Benzol plant of our arsenic acid. We got it in two gallon glass bottles, and we had to account for that, and we put it in our inventory which had to be turned into the accounting department. It was credited to the lead arsenate plant and charged to our plant. I can't say whether it was charged to the Pure Oil Company. The Sales Department would bill the Pure Oil Company either for the acid, the arsenic acid, or for the combination, and I don't know how it was handled. I think this entry, 2 gals. arsenic acid, Pure Oil, is my handwriting. Most of these,—quite a number of these are my handwriting, but they are not all my handwriting. Mr. Reid made several notations. This is my writing. Here is Mr. Reid's writing here. I think I put this notation on this particular sheet at the end of the month, but I am not absolutely sure. I have had this shipment record in the file in my office since 1932.

The records of which you show me photostats for the month of June and the month of July, 1932, are abstracts. We have no other shipping record of these shipments than the book I have produced. What you have shown me are abstracts. This is the original shipping record right here.

Mr. Lyon:

Q. That does not seem to be the same either, because you can't identify these sheets that I have shown you the photostats of? A. They are not taken directly from this record. They appear to be an abstract of this record. The order numbers are the same, but they have omitted, I think, shipments such as some of our commercial shipments of 18 and 22 Baume acid.

Q. Now let's go back to the February 1932 shipping record, your original shipping record. In what form did you receive instructions to make the shipment to the Pure Oil Company February 11, 1932? I notice your shipping record shows order #38118. A. That is the regular Sales Department order. I received such an order from the Sales Department.

Q. Was it specified on that order that you should

also ship some arsenic acid? A. I can't answer that definitely, I am afraid. We had instructions to do that. Whether it was printed on the order or whether it was phoned in to us, I can't say.

Mr. Owen:

You don't mean, Mr. Lyon, to infer the arsenic acid was shipped separately from the hydrochloric?

Mr. Lyon:

I am trying to find out—

Mr. Owen:

(Interrupting.) The form of your question indicated the arsenic acid was shipped separately.

Mr. Lyon:

Oh, no, no. I didn't mean to infer that. This shipping record has some lines below the last entry for the month, just a notation "2 gal. arsenic Pure."

Q. It doesn't say what about it any more than that? A. That is the only Pure Oil shipment of the month.

I think I probably put that notation in at the end of the month. I can't say whether the order I received from the Sales Department for this shipment #38118 showed that we were to include with that acid that arsenic. I do know some of the orders received did specify. In later shipments the orders did specify we were to add the arsenic, I remember that. The photostat you show me of order 38118 looks like one of our orders. It has the correct order number.

Mr. Lyon:

I will ask counsel if there is any question about this photostat being a correct photostat of the order in question (handing same to Mr. Owen).

Mr. Owen:

There is no question but what that is a photostat of the order.

The Court:

It's good enough for me if they want to put it in the record.

Q. You don't find on that order any reference to any

shipment of arsenic material, do you? A. It doesn't appear on this order.

This shipment record for March begins and sets forth, commencing at the top, consecutively down, that we made six shipments of hydrochloric acid from our plant in March, 1932. And then below that there is a total of the March sales and some percentage figures of some kind. And then down below, several lines further down, entirely detached, is what appears to be a notation "2 gal. arsenic Pure Oil." I believe that is in my handwriting. That probably was written in there at the end of the month.

Q. Why wasn't it included in the entry for the shipment at the time the shipment was made? A. The purpose of this is to provide accounting for all materials used or sold. At that time we didn't make individual entry of that two gallons, evidently. There may have been other shipments in the balance of the month. Our purpose was to put down the total in order to account for the material.

The photostat you show me of order No. 3537 of The Dow Chemical Company, Pure Oil Company is the order 40327, the order number for this March shipment to the Pure Oil Company. It does not show any reference or contain any item calling for the shipment or the inclusion of the arsenic.

Mr. Lyon:

I understand counsel to say that there are no bills showing the inclusion of the arsenic material for the February shipment, and I would like to have—

The Court:

He didn't say that he was sure about that.

Mr. Owen:

No, I am not sure about that. We are willing to produce whatever we have.

Mr. Lyon:

Well, I would like to have the bill for this March shipment, if you can get it.

Mr. Owen:

We will produce the bills for the first—how many would you like, Mr. Lyon?

Mr. Lyon:

Just for those two (indicating).

The Court:

When do you claim that you began to charge for this?

Mr. Owen:

I think the first charge was on March 11, 1932, at least that is my understanding.

The Court:

And you think they kept it up after that?

Mr. Owen:

Yes.

The Court:

Well, you can bring in the first two, and then be prepared to tell us if you did charge for it every time thereafter.

Mr. Owen:

To the Pure Oil Company. I think possibly that free treatments were given to some other oil companies, just to get them interested.

The Court:

I see.

The Court:

Do you charge so much a gallon, or do you do like they do in automobile concerns, make a charge for time and material both?

Mr. Owen:

I think they charge a lump sum for the material and the—

The Court:

Then you are not going to get what you expect. This is an inter-departmental charge that you have got here.

Mr. Owen:

Yes.

The Court:

If it turns out the way he thinks, it is going to be different from what you think. I understand that they just made a lump charge of so much for a well, is that right?

A. I cannot answer for the accounting end of it.

The Court:

Did you say that it was labor and material?

Mr. Owen:

I think that will all be cleared up by a later witness, who will undoubtedly have access to these records. We were selling service. We did not charge merely for the acid. We made a lump charge for the acid, including the service of putting it into the well.

Mr. Lyon:

We have the order number. We have certain photostats of later orders, Your Honor.

The Court:

But, what I understand, those are inter-departmental orders.

Mr. Lyon:

They show a charge, they show an order from the company and they show one part of arsenic acid, $3.19 to be charged, I suppose, to the company.

The Court:

I don't know. That is what they are going to let us know.

Mr. Lyon:

That is what the customer is ordering on the order sheet.

The Court:

Is this an order from the customer or an order from one department to another? A. Those are the orders we receive from the sales department to make the shipment. That is not an inter-departmental order.

Mr. Owen:

This is not a billing to the customer, is it? A. No.

Mr. Owen:

It is an order. A. It is our order to make the shipment.

Mr. Owen:

It is an order to your department to make the shipment. A. That is right.

The Court:

I thought it was a department order. One department to another.

Mr. Owen:

That is what it is, Your Honor.

A. It is from the sales department to the plant to ship.

Mr. Lyon:

Do you know whether they bill the customers for any of this arsenic acid on the bill? A. The billing is an entirely different department. I can't answer that.

The Court:

Different price, probably, too, but we will have to find out about it. You are just guessing, you and I.

Mr. Lyon:

So that I can explain the point, we will offer proof to show under this patent to the Pure Oil Company, the Pure Oil Company went to the Dow Company with their invention in December, I think, 1931, and it is our understanding that actual shipment of ordinary acid, commercial acid, without any inhibitor, was made to the Pure Oil Company and used by the Pure Oil Company in acidizing wells; couple that evidence with evidence when this application was filed, and prepared,—the information was, it was written down, that this use of this inhibitor was optional and not necessary in the process, and now that they are finding there is nothing to talk about it in the language of the patent except the inhibitor, they are making the inhibitor their all-important thing, whereas it started out with the Pure Oil Company idea of reviving the old Frasch process.

The Court:

This is mighty important, what we are talking about here now, and the very fact that is written on afterwards. I don't mean there was a juggling of the books for the Patent Office, but it may be it was put in their order, and you filled out the order for that, and somebody went back and thought they used two gallons in everyone of those. I don't know what. But, if it seems to be inserted in there, we better get to the bottom of that.

Mr. Owen:

We will try to clear that up, Your Honor. Now, the next thing I have is Mr. Hall's shipping record. Mr. Hall was a witness, Your Honor will recall, and he produced a typewritten list of acid shipment records which is in evidence as PX-12. On cross examination counsel called attention to the fact that the shipment record of hydrochloric acid for February, 1932, has an entry "2 gal arsenic Pure Oil" written at the bottom below the other entries, and Mr. Hall testified that he couldn't recall when he made that entry, which he thought he made at the end of the month.

Now, in order that the record may be complete I am going to offer a photostat copy of the sheet containing the shipment record of hydrochloric acid for each month during the first half of the year 1932.

And I call attention to the fact that in the January sheet there is no entry showing a shipment of hydrochloric acid to the Pure Oil Company, and there is no entry showing a shipment of any arsenic acid during that month; that in the record for February there is one item, which is No. 2 on the sheet and reads:

"2-11, order No. 38118, Pure Oil Co. Mt. Pleasant oil field, one wagon, 15 per cent HCl," and then under the column "Net weight," "790," and down below the other entry, there are seven entries in a row, and then below that is written this entry:

"2 gal. arsenic, Pure Oil."

In the March sheet item No. 2 is dated 3-11, the order is 40327, Pure Oil Co., oil field, it looks like 5000 pounds of 15 per cent, and underneath "Net Weight," "750."

Then down below the other entry is an entry similar to the one on the February sheet, reading:

"2 gal. arsenic, Pure Oil."

On the sheet for April there are two entries indicating shipments to the Pure Oil Co., No. 2 being dated 4-5, the order number 42,252, Pure Oil Co., Oil field, one tank W., looks like 68 cubic feet, 15 per cent HCl. It is not very

clear. The net weight is 750, and item 4 is dated 4-7, or 2-7, I can't tell. I think it is April 7th. The order is 44094, and the consignee is Pure Oil Company, Mount Pleasant, Michigan, one tank W. 68 cubic feet, 15 per cent, and the weight is 750.

And at the bottom of that, or below the entries on that sheet appears this entry:

."4 gal. arsenic acid, Pure Oil."

The next is the shipping record for May, 1932, and it contains six shipments to the Pure Oil Company, Mount Pleasant, Michigan, being Nos. 2, 6, 7, 8, 9 and 10 on the list, and the amount of the shipment is 750 net pounds in each one, net weight, and below on the page is this entry:

"12 gal. arsenic, Pure Oil."

Then there are two sheets for June, and they contain, as I count them, 13 shipments to Pure Oil Company, and then shipments to other companies, the Columbia Oil & Gas Company, and different ones; and at the bottom appears this entry:

"44 gal. arsenic, Pure Oil; 28 gal. arsenic, Misc."

Now, some of those Pure Oil shipments were of 1500 net pounds, instead of 750 net pounds. For instance, entry No. 21 was for 1500 pounds, and entry No. 23, entries 24, 25, and 26, each for 1500 net pounds, and No. 28 also, and No. 31, and No. 33—those were all shipments to the Pure Oil Company.

Mr. Owen:

So I will ask that copies of those sheets for January, February, March, April, May and June of 1932 be photostated and offered in evidence as one exhibit, and marked PX-246.

The Court:

That will be done.

(The photostatic copies will be marked Plaintiff's Exhibit No. 246.)

The Court:

The purpose of the reading was so that the record might show the portions of this that you relied upon?

Mr. Owen:

Yes. The purpose of it was this, that those shipments to the Pure Oil Company of hydrochloric acid, and the entries of shipments of arsenic acid to the Pure Oil Company, register in every instance 2 gallons of arsenic acid to 500 gallons of hydrochloric acid.

The Court:

The first one was no charge?

Mr. Owen:

The first one was no charge, but the entry of arsenic acid is the same.

The Court:

The same for that one?

Mr. Owen:

Yes. And then it is there for the second, third, fourth, and so on.

Mr. Lyon:

It is not in accordance with the keeping of regular books. It is down at the bottom.

LAWRENCE W. LEE,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I am an employe of Dowell, Incorporated, and I live at Midland, Michigan. I have been an employee of Dowell, Incorporated, since 1932. Previously I was employed by the Dow Chemical Company since 1928. I was in the Service Department of the Dow Company and had charge of trucks, yards, and the general clean-up of the plant. I recall the time when the first oil well was acidized by the Dow Chemical Company for the Pure Oil Company. Our particular department transported the acid from the plant to the well location, it was my duty to secure a receptacle from the Acid Division in which to transport the material. The container for the acid was a wooden tank normally used by the Acid Division for transporting acid between plants. That was the first time one of those tanks had been used for such purpose, as far as I know. That was in 1932. I know that from tying it into other treatments which came later and in which I was personally interested. That first shipment made to the Pure Oil Company was before May of 1932. It was approximately sixty to ninety days before May.

By Mr. Owen:

Q. What is there about May that fixes this in your mind? A. In May of 1932, I made arrangements with the Dow Chemical Company to secure some inhibited acid, and the services of one of their men, for treating some wells in which I was interested.

I actually saw the inhibitor go in the first well that was treated for me, and I had knowledge of their previous use of inhibitor in the acid they were using in the wells of the Pure Oil Company. I knew about that by discussions with Ross Sanford, whom we worked with very closely, and with Dr. Grebe of the physical laboratory.

Q. And when, with reference to that first shipment of hydrochloric acid to the Pure Oil Company well, did you have occasion to have conversation, the first conversation with Dr. Grebe and Mr. Sanford, or either of them, on the subject of an inhibitor in that acid? A. The first conversation with Dr. Grebe was previous to the Pure Oil treatment, and it occurred after our department had trucked acid in carboys to a Dow well directly in front of the office from which we operated. And the purpose, my purpose in talking with Dr. Grebe was to find out what protection we should give our men in handling the acid which was going into this well. And at that time we discussed the handling of the acid and the manner in which it was going to be put into that well. That was previous to the first Pure Oil Company treatment. In my opinion it was a few months before. I do not recall whether or not during that conversation anything was said on the subject of inhibiting the action of the acid on the well equipment. I first learned that an inhibitor had been used or was to be used in this first Pure Oil treatment about the time I was making arrangements for securing the tank to take the acid to the field for that particular treatment.

Q. Then before that treatment was made you had information or had been informed that they were going to use an inhibitor in the acid; is that correct? A. Yes, sir.

Mr. Lyon:

I object to that as leading and suggestive.

The Court:

"About the time," I would rather you wouldn't—let's let him fix it as near as he can with reference to when he actually took it out. That is all that we can get now. A. It was at the time that the first treatment went to the field of Pure Oil that we discussed the use of the inhibitor.

The Court:

At the very time, you mean? A. Yes, sir.

The Court:

The very day? A. Within one or two days. It was at the time we took it up.

By Mr. Owen:

Q. How are you able to state that you talked about inhibitors at or within one or two days of the time of that first Pure Oil treatment? A. Well, in discussion of how it was to be handled Mr. Grebe stipulated that Mr. Quinlan, who worked for Grebe in the lab, was to put in the inhibitor and would handle the mixing of it, as there was danger in handling the material that they used.

I learned at that time that the inhibitor they proposed to use was arsenic acid. It was to be obtained from the lead arsenate plant. It was a product or by-product of that plant.

Q. Now, after that first treatment, when did you next discuss this question of an inhibitor being used in the acid, if at all, and with whom? A. The next time that I can remember discussing the use of the inhibited acid—

The Court (interposing):

Is that the first acid that went to the field? A. That is the first acid that went to the field; yes, sir, to the Pure Oil well.

The Court:

Now, is there any relation between that—you have already told us about using a wooden tank? A. Yes, sir.

The Court:

Did the talk have anything to do with the wooden tank? A. We had to secure a tank or some receptacle for taking it to the field.

The Court:

Yes, but what about this emphasis of the wooden? Was that emphasized in any way when you talked about it? A. No. That is the only receptacle we had at the time for taking it to the field.

The Court:

That is the only one you had? A. Yes. I made contact with Mr. Curtiss of the Sales Department for the purchase of sufficient acid to treat five wells, five hundred gallons to each well, and it was stipulated that Mr. Quinlan would have the inhibitor and assist or supervise the treating of the wells, and that was done.

Q. I call your attention to Exhibit 12 in this case, which is a list of shipments of inhibited acid produced by Mr. Hall, and on this list I find under date of 6/4/32 an entry of a shipment to Lawrence Lee of 500 gallons of 15 per cent acid, and a note on the margin of the use of arsenic in connection with it.

This was one of the treatments that I have just referred to. On that treatment I saw the inhibitor go into the tank. The entry under the date of 6-9-32 also was one of our wells. I do not know by definite observation whether or not an inhibitor was used in that acid. There was an understanding on that subject. All of the acid to be bought was to be inhibited acid.

Mr. Lyon:

We are not contesting that. It is in agreement. You can put that summary in. We agree, commencing in June that these wells were treated with inhibited acid, with acid containing inhibitor.

Mr. Owen:

Well, then, I won't pursue that line any further.

The Court:

Well, now, the first well this witness has testified about was in 1932?

Mr. Owen:

The first well he was personally interested in; the first well he has testified about was the Pure Oil Well treatment of February 11, 1932.

The Court:

All right. What has he said about the inhibitor in that?

Mr. Owen:

Will you repeat what you said about the inhibitor in that first treatment for the Pure Oil Company? A. I stated that I personally made arrangements for obtaining the receptacle in which the acid would be transported to the field and I stated that I discussed the use of inhibited acid with Mr. Quinlan and Mr. Grebe previous to that at the time.

The Court:

You had to do with the transporting, as I understand? A. Yes.

The Court:

Why were you concerned whether it was inhibited or not? I find no connection for the reason you happened to do that. A. I am responsible for the men in that division and our men were handling the material. They were loading the acid and would be transporting it to the field. The information regarding inhibitor was advanced by Mr. Grebe's department inasmuch as he considered there was a certain amount of risk in putting in the acid or handling it physically, and he wanted his own men to put the inhibitor in instead of the men from the Service Department.

Mr. Owen:

I think what the court wants to know is how you happen to know so much about furnishing the truck for that first equipment. A. Dr. Grebe discussed the handling of the acid. I am talking about the arsenic acid, which is the inhibitor which goes into the tank.

The Court:

Is that dangerous to a man? A. Dangerous if it gets on your hands, finger nails.

The Court:

More than the hydrochloric? A. Yes, sir.

The Court:

I know acids and I don't see why a chemist would discuss with the trucking department what kind of acid.

Witness:

I worked for the Dow Company up to about the time Dowell was incorporated and then went over to them. My first duties for Dowell Incorporated were building of equipment, starting stations in the field and the operations in the field. I installed stations during the early period at Louisiana, three stations in Texas.

The first station was opened at Midland, Michigan, operating from The Dow Chemical Company; the next station at Muskegon, opened in September, 1932. Our depart-

ment moved the equipment over there, and two of our men from that department were transferred to that station about that time. The next station was opened in North Baltimore, Ohio. I was working with Dowell at that time, at the time that was started. Horse Cave, Kentucky, was the next station. Manning, Louisiana, was the next station. That was started in December of 1932, although no equipment arrived until January of 1933. Texon, Texas, in January of 1933. Russell, Kansas, approximately the same time, in January of 1933. Then Breckenridge, Texas, in February of 1933.

I am now in charge of the purchase of materials, auxiliary treating materials, and have been in that branch of the business since March of 1933. Since that date I have had knowledge, through my purchasing of materials, of what was being used. My records show what this inhibited acid was called. It was called Dowell X. They started calling it Dowell X in 1933. At one time before that it was known as Dow limestone solvent. It has been called Dowell X since that name was adopted. That indicates in our accounting, inhibited hydrochloric acid of 15 per cent strength.

The advertisement, photostat copy of which you show me, appeared in the Oil and Gas Journal for December 1st, 1932. This advertisement is familiar to me. I saw it at the time it came out.

Mr. Owen:

I will offer that as Exhibit 15.

(The photostat of advertisement referred to was thereupon marked PX-15, July 24, 1941.)

CROSS EXAMINATION

Referring to this first order for the job of the Pure Oil Company, dated February 11, 1932, I saw the load leave the yard, I saw the load leave the service station.

By Mr. Lyon:

Q. Are you sure that that was not called for by the Pure Oil Company with its own truck? I will show you the order to see if that will help you refresh your recollec-

tion (indicating). It specifies on the order, to be called for by the Pure Oil Company truck (handing the document to the witness). A. (After examining the document): I would think that it would be called for by the Pure Oil Company if this order says so. I have no actual recollection as to whether it was or not. It was shipped in a wooden tank, I am sure of that. I made the arrangements for securing the tank.

Q. Did you actually see the shipment, see the wooden tank put on the truck? A. I saw the—no, I would not say that I did.

The Court:

Just let me understand you. If they called for it with their truck, would that still mean that it was in your tank? A. Yes.

The Court:

You know that it would not be in their tank? A. Yes.

The Court:

Obviously, a truck used in that business, might go over and get stuff dumped into it and go away with it, but that is not right in this case? A. That tank when it came in would have to come in the gate, and when they came in with the tank—

The Court:

You mean tank or truck? A. When the truck came in, it would come in the gate, and it would come over to the department where the tanks were. Then it would have to be taken from the wooden trucks on which it was carried around the plant, and put up on their truck, if their truck was used, and tied down when loaded. A wooden tank would be put on another flat bottom truck.

The Court:

They don't have trucks like we use for the threshing machine? A. They do now, sir. They didn't at that time.

Q. Didn't the Pure Oil Company have such tank? A. Not at that time. They later built a tank.

Q. Now, why was it necessary to ship the acid in a wooden tank? A. I don't know as it was necessary. That

was the only receptacle we had in the plant which was available for that use.

Q. You did not have any other tank in the plant at all except a wooden tank? A. That was the only thing we were using for acid at that time.

Q. I understand that. Why did you use a wooden tank for acid? A. Hauling acid you would naturally think of the acid receptacle that you had around the plant.

Q. I mean why did you have wooden tanks around the plant to carry acid? A. The acid hauled around the plant is raw acid.

Q. And, you had never thought here in the Dow Company of adding an inhibitor to your acid so that it wouldn't corrode metal tanks if you used metal tanks? A. Well, I am not an authority. If you want my opinion I would be glad to give it to you.

Q. I am trying to find out why did the Dow Company go to the trouble of handling the acid in wooden tanks. Was it because— A. (interrupting) They want the acid in the pure form. They are using it in a process.

Q. What process? A. Processes around the plant. They are hauling from one plant to the other in their work, and manufacturing processes. It is taken from one plant to another for use in reacting other processes.

Q. Do you know whether the inhibitor would interfere with any of these processes that the acid was to be used for? Do you know that of your own knowledge? A. No.

Q. Well, how long was it after this shipment to the Pure Oil on February 11 before your company got a steel tank to handle acid? A. The first record I have is in August or September of that year. They may have been built earlier. I don't know. Then after that we shipped our acid from the stations out to the wells, to the point of use, in steel tanks and the acid contained the inhibitor. The inhibitor was added at the station. We have continued that practice up to the present time since at least Septem-

ber, 1932, that has been the regular practice in our company.

We started using arsenic acid as the inhibitor and continued it until the fall of 1932. We then used an inhibitor which we call Retarder, made in our own plant. I am not familiar with the contents of it, but understand that it was a mercaptan base material. Mercaptan is a sulphur compound. I don't know where it came from. You can smell it in some of these Michigan oils. We have used it at intervals. We are still using that same inhibitor in refined form. It is the principal inhibitor we have been using practically all the life of Dowell. That is, we have used it all through Dowell. And at the present time it is the only inhibitor we are using, with the exception of one other inhibitor, which is a material purchased from the Barrett Company. They sell it for pickling. They sell it to the trade as a pickling compound. It has been about a year since our company has used any arsenic acid or other arsenic compounds or agent.

All the acid that we transport out to the field from our stations contains an inhibitor, and in many cases this added surface tension reducing agent, and it is that acid which you pump down or introduce into the well through the well tubing. For some time we bought an inhibitor from the American Paint Company, from 1934 to 1936, or 1937. I believe that we bought our first in late '34 or early '35, and we bought our last in '36, I believe. That was an inhibitor or a pickling compound called Murodine. We used that for several years in conjunction with our own material as a retarder. In some cases we have used it alone. When we used it in conjunction with our own material, we mixed it with our mercaptan. We bought the Murodine from Mr. Gravell's company, the American Chemical Paint Company.

RE-DIRECT EXAMINATION

We now use wooden tanks for transporting hydrochloric acid from one of our plants to another. As to whether we ever used any other kind of tanks for that purpose, we have used some rubber lined tanks and may be using them now. I am not positive of that. But we never used any unlined steel tanks to my knowledge.

The reason why steel tanks, unlined steel tanks, are not used for shipping or transporting acid from one plant to another in our plant at Midland is because the raw acid would attack the steel tank. There is no reason for inhibiting it in the tank from one place to another, and lots of the processes in the plant, in my opinion, there is a possibility that it would throw off the reaction. We wouldn't want to use it. In other words, pure hydrochloric acid or commercial hydrochloric acid is desired for reaction in our plant.

RE-CROSS EXAMINATION

In our company ever since September, 1932, we have used unlined steel transportation tanks for conveying the acid from our stations out to the wells in which it is to be used. Since we first started, that would be August or September, or in that summer, 1932, to my knowledge we have only transported acid to our customers in unlined steel tanks.

RE-DIRECT EXAMINATION

When The Dow Chemical Company first began to acidize oil wells for the purpose of increasing production there was no one else in that business, to my knowledge. There was some competition started in Michigan in the summer of 1932. That was a firm known as the Oil Makers. It constituted Edgar S. Lee and a man by the name of

Dougherty. They continued in business about a year, I think.

The Court:

Where were they located? A. Edgar is my brother. Located in Midland, Michigan. Dougherty is the driller on the wells which were treated by our company or myself, the driller that drilled the wells.

Q. And were they working under any arrangement with the Dow Company? A. I think that they purchased inhibited acid for one or two treatments but outside of that, they got their material from other sources. I do not know why they stopped.

Mr. Lyon:

If Your Honor please, I think this evidence about other people is immaterial and irrelevant. It is subsequent to the application for the patent. How would we meet it or what collateral issues would it bring in in this case if we wanted to question why it stopped? It isn't worth trying, I don't believe, all those matters.

The Court:

It is material in that it shows the growth of the business; that theory that revolutionized the business along that line. As they started up, others tried the same thing.

Mr. Owen:

That is the purpose of it.

The Court:

It hasn't very great weight, I will assure you of that, but I will let you show it.

Witness continuing:

A man by the name of Ricou, Shreveport, Louisiana, and a company later known as Chemical Process started along about that time, thereabouts. It would be the fall of '32 or early '33.

The Court:

Where were they located? A. In Breckenridge, Texas. Williams Brothers Company came into the picture in 1933, I believe. They were the ones that were sued.

RE-CROSS EXAMINATION

I have heard of The Chemical Process Company. They started in business in the fall of '32, as near as I know. They are still doing some business. Their main office is at Breckenridge, Texas. They operate in Texas, operate some in Oklahoma, I believe they are operating some in Louisiana, and some in Kansas. They have no rights to operate under the Dow patents, to my knowledge.

Q. And you don't claim that they use inhibited acid? A. I don't claim anything about the process.

Q. Don't you know what they use? A. No, sir. Their business is acidizing oil wells and they are a direct competitor of the Dow people and have been before the Halliburton Oil Well Cementing Company went into this business. They are still in business and we are not now suing them, to my knowledge. I wouldn't know whether we sued them in 1934.

Mr. Lyon:

If Your Honor please, I will offer in evidence at this time a certified copy of the papers on file in the United States District Court for the Eastern District of Oklahoma in the suit entitled The Dow Chemical Company, plaintiff, vs. The Chemical Process Company, defendant, in Equity No. 4523. This consists of a bill of complaint for infringement of the Grebe-Sanford patent, an answer filed by the defendant, a set of interrogatories propounded to the defendant, the defendant's answers to the interrogatories, and a stipulation that the cause be dismissed, and an order dismissing the cause.

Mr. Owen:

Dismissal without prejudice.

Mr. Lyon:

I will ask that this be marked Exhibit 16. (Exhibit 16 marked.)

FRED H. BROWN,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I am assistant treasurer of the Dow Chemical Company. Previously I was assistant secretary for about four or five years. As assistant treasurer I have access to the accounts of the company, and here produce the records of shipments of 15 per cent hydrochloric acid by Dow Chemical Company to the Pure Oil Company, beginning in February, and running on through for several months during 1932.

By Mr. Owen:

Q. Will you explain what these are that you have produced? A. The first bundle is our original invoicing instructions consisting of ten sheets. The first sheet is dated February 11, 1932, and it is made out to our Chlorbenzol department. This form is filled out by our sales department and goes in duplicate to our traffic department. This buff copy is retained, and the yellow copy goes out into the plant. The ones I have produced are retained in our traffic department, and a yellow copy goes out into the plant or the department to fill the order. All of the typed information with the exception of the price is on that yellow copy. That first one happens to be a no charge order.

Q. And the next one, which is Order No. 40327, has typewritten matter and also the entries in pencil. Will you explain what those entries are? A. Well, all the typed material, all the typing is on the form which goes into the department, with the exception of the price.

The Court:

The sales department makes out the typing? A. Yes, they make all the typing. The sales department fills in the price in the copy which it keeps, but the price doesn't go on the copy to the other departments.

Referring to the typewritten matter on this first order No. 28118, the department is "Chlorobenzol" dated "February 9, 1932," and the "Invoice To" block is written "Same," because it says "Ship to Pure Oil Company" and if they are the same we usually write "Same" up there, and the X "Ship to" is "Pure Oil Company, Mount Pleasant Oil Field," and "To be called for by Pure Oil Company Truck February 11th." Down below there is originally written "70 carboys hydrochloric acid," and in parentheses "Strong," and "No charge" in the price column. "70 carboys" was later changed to "one wagon load."

Then on the second one of these orders, which is Order No. 40327, under department is "Hydrochloric Acid" and in parentheses "Don Hall" in charge of that department. Dated March 9th, 1932. Invoice to "Same" "35 East Wacker Drive, Chicago, Illinois." The date to be shipped is "Will call for March 10, 1932." It was shipped to Pure Oil Company oil fields, and the route is "Pure Oil will call for," and the special instruction to traffic and shipping clerk "Pure Oil will call for March 10, 1932." The shipment was to consist of 500 gallons approximately 10 degree Baume hydrochloric acid to be loaded in tank wagon, and there is a "plus handling charges" and "crlc" or whatever.

The Court:

Would that be about fifteen per cent, when it is all loaded?

Mr. Owen:

It is just about fifteen per cent.

Q. Now, the order No. 42252, which is the next one, I see is to the same department and to the same company, the Pure Oil Company, the same shipping instruction. Will you read what the shipment was to be? A. Five hundred gallons approximately 10 degree Baume hydrochloric acid, plus two portions arsenic acid. Total $6.38, and labor tank service transferring charge, that is $5.80.

For order 40327 there was a total charge of $22.18. It

was 500 gallons approximately 10 degree Baume hydrochloric acid, figured out at 4500 pounds, at $14 per ton, on the basis of 18 degree acid, came to $17.50. And then there is a handling charge, $4.68, making a total of $22.18. The next invoice or the next order, 42252, calls for 500 gallons approximately 10 degree Baume hydrochloric acid figured out to 2500 pounds at $14 per ton on the basis of 18 degree acid. That is a total of $17.50. Plus two portions arsenic acid, $6.38. And labor tank service transferring charge, $5.80. Total $29.68.

The invoicing date of order 38,118 was February 11, 1932. Order 40327 invoicing date was March 11, 1932, and order 42252 invoicing date was April 5, 1932.

The Court:

Does that make three or four shipments of acid?

Mr. Owen:

Three.

The Court:

And the first one no charge?

Mr. Owen:

No charge. I am going to show later from the ledger sheet the payments made.

The date of the next one, Order 44,094, was May 3, 1932, for 1 Tank Load 500 gallons Dow Hydrochloric Acid, Approximately 10 Baume, $17.50. One portion Arsenic Acid, $3.19, Labor Tank Service Transfer Charge $4.00, a total charge of $24.69. That shipment went to the Pure Oil Company? A. Yes, sir.

Q. Now, will you go through each of these other six order numbers and state—they were all shipped to the Pure Oil Company? A. Yes, sir.

Q. State in connection with each order the order number and the material shipped and the price charged for the material. A. Order 44793, invoice date May 5, 1932, called for 1 tank load 500 gallons Dow Hydrochloric Acid, approximately 10 degrees Baume, $17.50; 1 portion arsenic acid, $3.19; labor tank service transfer charge, $4.00. Total $24.69.

Order 46068, dated May 21, 1932, 1 tank load 500 gallons Dow Hydrochloric Acid approximately 10 baume, $17.50; one portion arsenic acid, $3.19; labor, tank service, transfer charge, $4.00, total $24.69.

Order 46377, invoice date May 25, 1932, 1 tank load 500 gallons of Dow Hydrochloric Acid approximately 10 baume, $17.50; 1 portion arsenic acid, $3.19; labor, tank service, transfer charge, $4.00; total $24.69.

Order 46567, invoice dated May 27, 1932, 1 tank load of Dow Hydrochloric Acid, 500 gallons, approximately 10 baume, $17.50; 1 portion arsenic acid, $3.19; labor, tank service, transfer charge, $4.00, total $24.69.

Order 46568, invoice May 28, 1932, 1 tank load, 500 gallons, Dow Hydrochloric Acid, approximately 10 baume $17.50, 1 portion arsenic acid $3.19, labor tank service transfer charges $4.00, total $24.69.

Order 46763, invoice date May 31, 1932, 1 tank load, 500 gallons, Dow Hydrochloric Acid, $17.50, one portion arsenic acid $3.19, labor tank service transfer charge $4.00, total $24.69.

The last seven orders were for the same amount of hydrochloric acid and each included one portion of arsenic acid and a charge for tank service, and the total charge in each one of them was the same amount, $24.69.

Referring to the second of these orders, which is dated March 11, 1932, I find no charge for arsenic, but in the third one I find charges for two portions of arsenic. The charge for these two portions of arsenic is twice the charge for one portion of arsenic included in each of the subsequent orders. The amount of hydrochloric acid in each of those ten invoices or orders was the same, 500 gallons.

Q. Now, I will ask you if you can account in any way for the fact that the second order included no charge for arsenic acid, and the third order included charges for two portions of arsenic acid, and each of the subsequent orders included charges for one portion of arsenic acid?

Mr. Lyon:

I object to that on the ground this witness can't testify

to anything except that he identifies these records. He doesn't know any more than the records, and the records speak for themselves.

The Court:

Witness, as you have only been assistant treasurer for a short time, I will ask you if as assistant secretary you did have access to these sheets and books? A. Yes, sir.

The Court:

During all the time you have been working there? A. Yes, sir.

The Court:

I will overrule the objection. Those familiar with accounts can read between the lines, where someone else can't, and I will let him interpret. A banker can tell you where a check went by his own system, while a stranger couldn't, at least with any ease, interpret it. All right witness. A. It is apparent that the charge for arsenic acid was omitted from the first shipping instruction and they were charged two portions on the following shipping instruction.

Q. And I will ask you whether or not the charge for the two portions in the third shipment and for no portion in the second shipment would be consistent with the fact that one portion was included with each of the second and third shipments?

Mr. Lyon:

I object to that as argument, and leading the witness.

The Court:

Pretty much that way. I will overrule the objection though and take the answer. A. I believe it was.

The Court:

I take it that his is more a line of reasoning and conclusion than what I thought was an interpretation of it. Isn't your line of reasoning quite largely based on the fact that at no time have you found so much of the inhibiting arsenic supplied and charged in any item as would be in the third, but that would be an unreasonable amount for them to use and put in from your custom and experience and the way it is done? A. That is right.

The Court:

And that seems to me with the other is the reason why there was no charge for it before.

Mr. Lyon:

Your Honor in your statement referred to the witness' experience in the way it is done. He hasn't any experience. He keeps the record.

The Court:

I agree my argument wasn't very good, but I can't get the answer. I didn't base it on what he would and I am glad he didn't follow my suggestion and didn't let me lead him, and it is very largely logic, but it seems to me it is a fair conclusion. I will let it stand and you can argue something else about it to me.

Mr. Owen:

I will ask that this bunch of ten orders to which the witness has referred be marked Plaintiff's Exhibit No. 231-A, B, C, D, E, and so forth.

(The documents above referred to were thereupon marked Plaintiff's Exhibits 231-A to 231-J, inclusive.)

The Court:

In other words, here the total, if I counted right, are nine charges, or was it some other number, or nine batches?

Mr. Owen:

Nine batches.

The Court:

Nine batches that went out. The first one they didn't charge for.

Mr. Owen:

There were ten batches with the first one.

The Court:

I didn't keep account of that. There were ten batches all told and all the books and everything show the first one they didn't charge for.

Mr. Owen:

That is right.

The Court:

Well, your nine uniform batches of inhibitor charged

for, if we spread even over there, but as it is there is the second one, no charge, and the third one would be what it is in all the others?

Mr. Owen:

That is right.

The Court:

And I would just naturally reach the conclusion that there was inhibitor in every one of the ten. The first one they didn't charge for and that they charged them for nine inhibitors, but they got two of them on one and none on another. All right.

I have here the accounts receivable record of the Pure Oil Company account. On Order 40327 is given Folio No. 3537, and that is posted on our accounts receivable, 3537 folio, dated March 14, a charge of $22.18, which corresponds with the charge on the order, without the arsenic. Order No. 42252 is given Folio No. 4516, was posted on April 5, for $29.68. That corresponds to the total of $29.68, and included the two portions of arsenic.

The Court:

It says "two portions."

Mr. Owen:

Yes.

Mr. Lyon:

This is a shipping order. It says ship two portions April 5.

Order 44094 is given Folio 5977, was posted on May 3rd, at $24.69. That agrees with the total on that order.

Order 44793 was given Folio 6121, posted on May the 5th, $24.69, and that agrees with the total of that order.

Order 46068 was given Folio 7105 and that was posted May 21st, for $24.69, and that agrees with the total of that order.

Order 46377 was given Folio 7323. That was posted May 25 for $24.69, and agrees with the total on that order. And that is true with all the rest of them.

Q. Does this ledger account show whether or not those items were paid for by the Pure Oil Company? A. Yes,

sir. When the checks come in, we make a check mark after the amount of the invoice, and those are all checked off. From time to time, the account is balanced.

Mr. Owen:

I will not offer these ledger sheets unless counsel wants them or the court wants to see them.

The Court:

I don't care to see them. I am satisfied.

CROSS EXAMINATION

The ledger sheet shows that the shipment of March 14th, which is the second shipment here referred to in the amount of $22.18, was paid March 31, before the date of the third shipment. It was actually paid by the Pure Oil Company before the date of the third shipment, and the amount paid for was just the amount of $22.18.

Q. And that is the amount your books showed was being charged for hydrochloric acid without any inhibitor in it without any arsenic in it, isn't that correct? A. I don't know whether there was any in it.

Q. I mean these records that you have produced here, these shipping records, you are selling hydrochloric acid at the rate of $14.00? A. Yes, sir.

Q. And the additional price was charged for arsenic above that rate? A. Yes, sir.

Q. And this record of this shipment of March 14, 1932 shows that the shipment was charged for at the rate of $14.00 and was paid for at that rate with no charge or no payment for arsenic? A. No, sir.

The Court:

And on all of those shipments one portion of the arsenic was charged at the uniform price each time? A. Yes, sir.

The Court:

And each time it was 500 gallons of the acid? A. Yes, sir.

The Court:

And the charge for that was uniform, too, as I recall it? A. Yes, sir.

The Court:

And the first one was never paid for because no charge was made; the second one was paid before the third one was delivered or charged for? A. Yes, sir.

The Court:

And they have all been paid for? A. Yes, sir.

The Court:

Well, we have all we can get from this witness.

Mr. Lyon.

I don't think this witness can help us any more. He would be guessing. We might as well guess as to ask him to guess.

SHERMAN W. PUTNAM,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I reside at Midland, Michigan, and am assistant general sales manager for the Dow Chemical Company. I have worked for the Dow Chemical Company since 1919, with the exception of a short time in 1929. My duties for that company during the period around 1931 and 1932 were doing market development work on the new products. I

had something to do with the sale or attempted sale of hydrochloric acid by the Dow Chemical Company to be used in acidizing oil wells. That came within my jurisdiction after it was started. It did after the first treatments were made. It first came under my jurisdiction, so far as sales were concerned, as I recall it, late in the summer of 1932. The interest displayed by those interested in the production of oil when news of this treatment was spread around was beyond anything that we had really hoped for in that line.

Mr. Lyon:

Well, to save time, Mr. Owen, you have been over this in depositions.

Mr. Owen:

Yes.

Mr. Lyon:

And the company received quite a large number of letters of which you have produced copies. If you want to produce them and offer them in evidence we will waive proof, without your inquiring in detail and identifying them with this witness.

Mr. Owen:

All right.

Q. Just state briefly, Mr. Putnam, the character of the inquiries that came to your attention when this sale of this fifteen per cent hydrochloric acid was placed under your jurisdiction, as a new product or a new use? A. Why, the inquiries came from all types of people, from the very largest oil companies down to all the promoters that thought they could go out and buy up all the old oil wells and make millions off from them.

Q. In what form did those inquiries come? A. Mail, telegrams, telephone, and personal visits.

Q. You testified in the Williams Brothers case, and at that time produced a number of original letters, possibly telegrams, I don't know; certainly a lot of letters, which came to you in that connection. I will hand to you what was introduced in the Williams Brothers case as Exhibit

No. 3, and will ask you if those represent all of the letters that came to you in connection with the sale of hydrochloric acid for use in acidizing oil wells, during the period covered by those letters? A. No. These would only be just a very few representative letters of the type that came in.

The date of the first letter I have here is June 13, 1932, and the date of the last letter in that bunch is January 19, 1933. As I have stated, these are representative of a large number, a much larger number of letters that came to me during that period.

The Court:

You may go ahead. Why do you not have that whole book marked as an exhibit?

Mr. Owen:

I am going to have the whole book marked as an exhibit, but I would like to get into the record at this time the names of the concerns from whom these letters came, which constitute this exhibit.

To the witness: Will you read just the names, without going into the contents? A. Sarnia Oil & Gas Company, The Ohio Producing and Refining Company, Perkins Brothers, Inc., William E. Schwartz, Stanolind Oil & Gas Company, American Pipe & Steel Corporation, Ltd., The National Refining Company, Indian Territory Illuminating Oil Company.

The Court:

That was one of Mr. Doherty's companies, a subsidiary.

Mr. Owen:

Yes.

A. Union Oil Company of California, Empire Oil & Refining Company, Gulf Production Company, Shappell Oil Company, Hercules Powder Company, Continental Oil Company, Central Utilities Corporation, Crystal Oil Refining Corporation, Jo H. Cable, Petroleum Engineer, R. H. Brownlee Laboratory, The California Company, Union Crude Oil Corporation, Capital Drilling, Inc.,

Laughner Oil & Gas Co., Bradford Motor Works, Anaconda Kevin Oil Company, United States Department of Commerce, Bureau of Mines.

Q. What did they have to say? A. This is written from Shreveport, and reads:

"In the August 29, 1932, issue of the Oil Weekly page 57, I notice an account of the increasing of oil production from a limestone reservoir by the use of acid. I was very much interested in this article and am wondering if you have any literature regarding the procedure and the kind of acid and amounts used in these experiments.

"Any literature or material you have would be appreciated.

"Very truly yours,
"R. E. Heithecker,
"Petroleum Engineer."

The list continues: C. E. Daugherty & Company, John A. Kay, Petroleum geologist, Cambridge Gas Company and Harvard Gas Company, Amory Petroleum Corporation, Lone Star Gas Company, Texas Pacific Coal & Oil Company, Brown Tool Company, Inc., Shell Petroleum Corporation, Simms Oil Company, Texoma Natural Gas Company, Humble Oil & Refining Company, J. & J. Petroleum Corporation, Texas Gulf Coast Production Company, United States Department of Commerce, Bureau of Mines, from San Francisco, California.

Q. What do they say? A. That is December 12, 1932:

"Gentlemen:

"I am interested in your chemical processes to increase oil production and wish you will kindly send me your booklet entitled 'How to Increase Oil Production.'

Signed "H. C. Miller,
Senior Petroleum Engineer.".

William C. McBride, Incorporated, and the Silurian Oil Company, The Empire Companies, J. S. Cosden, Incorporated, B. V. Von Vitanyi.

Q. Where did that come from? A. Germany.

Q. Will you read that?

"From your advertisement in the 'Oil Weekly' I read about the development of a new chemical process for the purpose of increasing oil production.

"Being the representative of the Ingersoll-Rand Company, 11 Broadway, New York, for Germany, I am greatly interested in the new process developed by you in view of my close connections to the German oil fields around Hanover.

"Please forward your booklet describing the new method and its adaptability to different oil formations. In case you think the method applicable to European oil fields I certainly would like to join your sales organization in some form.

"Referring you to Messrs. Ingersoll-Rand Company for any information you may desire about my person, I hope to have an early answer from you.

Signed "B. V. Vitanyi."

Q. What is the date of that letter? A. That is December 15, 1932.

Q. Then go on and give the names of the other parties from whom you received letters? A. R. B. Laing, Gypsy Oil Company.

Q. Will you read the one from the Gypsy Oil Company? That is the last one, I believe. A. Yes, sir. It is dated January 19, 1933, and reads:

"We have noted with interest the result of acid treatment as applied to oil wells, and the rapid spread of this method of treatment throughout the Mid-continent area.

"We have in mind the possibility of treating certain of our wells in the State of Kansas, and in this connection would like to know whether or not your company will be prepared to service wells in that area within the near future. If you have a specific plan formulated, we would like to know the date on which your service will be available.

Signed "G. G. Sanderson,

"General Superintendent."

Mr. Owen:

These letters will be offered as one exhibit, No. 13.

(The letters above referred to were thereupon marked PX-13.)

To the best of my knowledge the article in the Midland, Michigan, Republican of June 9, 1932, under the heading "Treat Wells by Dow Process to Jump Production," was the first newspaper or trade journal publicity that was given this treatment. I recall having seen the article in the Oil Weekly of August 29, 1932—page 57—at about the time it was published.

Q. I also show you a photostatic copy of another issue of the Oil Weekly, page 103, but there is no date on it. I cannot tell what the date was. Do you recall about when that was published? A. Why, this came out, I believe, in late '32.

Mr. Owen:

Mr. Conner just told me it is dated November 14, 1932. I will write that date on with the understanding if it is incorrect it may be corrected.

These three photostatic copies of publications will be offered as Plaintiff's Exhibit 14, and I wish to read into the record the first paragraph of the article in the Midland Republican for June 9, 1932.

The Court:

I will admit them as one exhibit.

Mr. Owen:

The first paragraph of the Midland Republican reads as follows: "A new process of injecting acid into oil wells, which is supposed to increase the porosity of the oil bearing sand and result in a heavier flow of oil from wells which have nearly stopped producing, was announced this week by Dow officials. Oil men are showing a keen interest in the process, which they believe would revive old wells, especially since it has been said to produce as much as ten times the original flow in one stripper."

The article in the Oil Weekly for August 29, 1932, states:

"Walter L. McClanahan Inc.'s Schaffer 1, Midland County, Greendale Township, SW. SW. SW. Section 12, which was drilled into the Dundee limestone about six weeks ago with an initial production of 125 barrels was boosted to 1070 barrels a day this week when treated with acid, a special solution developed by Dow Chemical Company of Midland, Michigan. The well flowed 750 barrels the second 24 hours after treatment and after five days was producing better than 500 barrels a day."

I will read also a part of the article which appeared in the Oil Weekly for November 14th, 1932, under the heading "Acid Makes Good Producer Out of Abandoned Well."

"Mt. Pleasant, Mich.—T. K. Buzard's Mahon 1, Isabella County, Isabella Township, Section 24, a well plugged as dry several months ago, flowed 368 barrels of oil in 21 hours after being cleaned out and run with a special acid limestone solvent solution. The well made 200 barrels the second 24 hours and is continuing to flow from 100 to 175 barrels a day.

"This is the first instance in Michigan at least where an abandoned well has been re-worked with commercial success.

"In the east field of the Central Michigan proven area, Braden-Saunders' Stapleton 3, Midland County, Greendale Township, Section 13, completed in September for 210 barrels a day, was boosted to 1700 barrels a day this week when treated with the acid limestone solvent."

The Dowell Company, and previously the Dow Company, was in the business of acidizing wells during the year 1932, and they began to advertise that service in trade publications in the fall of 1932, after Dowell Incorporated was organized.

CROSS EXAMINATION

By Mr. Lyon:

Q. Mr. Putnam, what prompted these letters and inquiries from the trade which have been referred to here, an announcement by the Dow Company in some form that they had a new process? A. As I recall it it was more word of mouth than anything else.

Q. Didn't you announce in these statements that appeared in the newspapers that you had a new process? A. Well, so far as we were concerned, we did not attempt to go out and get publicity early in the oil treating business. We announced to the trade that we had a new process, at some time during the year. I wouldn't know exactly when that was. As to what we announced regarding the new feature of the process, I would want to refresh my memory by looking at some of the things we wrote up at that time. I don't remember whether or not we told the public that the thing that was new about our process was that we were adding an inhibitor to the acid, and that was the only thing that was new. As to whether or not we announced to the public that we had a new process employing a new acid and didn't even tell the public what the acid was, I would have to go back and see how we handled that. That was nearly ten years ago.

I testified before Judge Kennamer in the Williams Brothers case.

Mr. Lyon:

Judge McDermott, in stating the grounds on which he reverses the lower court, why he holds this invention says:

"Patentee expended substantial sums to demonstrate the utility of the invention before applying for the patent."

Now, as appears at page 68 of the printed record on appeal, you testified as follows before Judge Kennamer, did you not:

"I can give you a part of the cost of the plaintiff in

its early development of the process in connection with the research laboratories, advertising, etc."

And you gave there testimony on which Judge McDermott based that finding. You understand that. A. Yes.

Q. You do not any longer contend that that testimony was correct, do you? A. If I so testified in the Williams Brothers case, it was correct to the best of my knowledge at that time, but it has been nearly ten years and I don't recall all the details.

Q. Well, you know, do you not, that money was not spent by the Dow Company in connection with experimenting with this inhibitor, at all, but was expended on some earlier work they had done on acidizing wells which had nothing to do with the Grebe and Sanford patent? A. Why, I couldn't answer that because you are getting into details now I am not familiar with.

Q. Well, you do not care now, you are not prepared now to repeat the testimony which you gave before Judge Kennamer and which was accepted in Judge McDermott's opinion as one of the bases on which he placed his opinion, you don't care to repeat that, to-wit, that some $11,000 had been spent, and so forth, on this invention before—not $11,000, but a very large sum had been spent on this invention before the patent was applied for on experimental work? A. I am very glad to repeat my testimony of that time if my memory may be refreshed.

Q. Now, had the Dow Company expended substantial sums to demonstrate the utility of the invention before the patent was applied for in June, 1932, and by the invention I refer to the addition of the inhibitor to the acid? A. If I so testified at that time, that was correct.

Q. I am asking you now to testify, had they, to your knowledge? A. Well, I don't recall now as to just what the dates, and so forth, were on that.

CALVIN A. CAMPBELL,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I live at Midland, Michigan, and am an attorney with the Dow Chemical Company. Head of their legal staff and one of the counsel in this case. I am not a patent attorney and look after the patent work only in a general way.

I have access to the licenses which are granted by the Dow Chemical Company. All licenses with respect, particularly, to these acidizing patents go through my office and through me personally. I have them with me.

By Mr. Owen:

Q. Will you go through them one at a time and state when each one was granted, and to whom, and if you can I would like to have you give them chronologically?

The Court:

You said something about licenses. You mean licenses under just the four patents in suit?

Mr. Owen:

No. They include the four patents in suit, and a number of others.

The Court:

You are not asking for all the licenses that they hold.

Mr. Owen:

Only the ones that include the patents in suit, licenses under the patents in suit, but those licenses—

The Court (interposing):

There are only four patents in suit?

Mr. Owen:

Yes, Your Honor.

The Court:

Then, all you are asking for is the licenses they hold under these four patents, aren't you?

Mr. Owen:

I am asking for the licenses that the Dow Chemical Company has granted to others under these patents.

A. Mr. Owen, in answering that question I assume you want the license agreements that have been granted but are not now in existence, is that correct?

Q. I would like a complete list of them chronologically whether or not they are now in existence? A. The first license agreement was between the Dow Chemical Company and Dowell Incorporated and was entered into on November 20, 1932. It has been superseded by a new agreement dated September 9, 1936, which is now in existence.

The next agreement is with the Pure Oil Company. The date of the first agreement between Pure Oil Company and Dow Chemical was January 1st, 1932, and that was superseded by a new agreement dated June 30th, 1934, and that agreement with Pure Oil Company dated June 30th, 1934, is still in existence. And the last dated agreement with Dowell is still in existence.

There was an agreement dated March 12, 1934, between the Texas Treating Company, a co-partnership of Dallas, Texas, and Dowell Incorporated relating to patent 1,877,504, which is not now in existence,—a license agreement under that.

The Court:

Has the Dowell Incorporated got the right to grant sub-licenses A. The Dowell Incorporated under its existing agreement, which is the one dated September 9, 1936, has the right to sub-license its customers under the patents mentioned in the agreement, to use the patents only in connection with materials purchased by customers from Dowell or a similar quantity purchased elsewhere. So, the agreement that Dowell made with the Texas Treating Company apparently was under a prior agreement which is not now in effect. At the present time Dowell has no right as such to sub-license under the patents other than what I have just stated to you.

The Court:

You mean Dowell Incorporated has no right? A. Dowell Incorporated, that is correct. Dowell Incorporated is Dowell. That is the way we generally refer to them.

The Court:

And Dow Chemical still retains the right to license others if they want to? A. That is exactly right. The agreements I am about to read are the license agreements that Dow Chemical has made with others.

The Court:

(Interposing): That is what I thought. That is what confused me here. This third one you mentioned is a sub-license. They are sub something from Dowell? A. That is correct. That agreement is no longer in effect, however.

The next is an agreement dated August 9, 1934, between the Stanolind Oil & Gas Company, and Dowell, Incorporated, and that falls in the same category as the previous exhibit that I mentioned with the Texas Treating Company and Dowell. That agreement is not now in existence, and it expired on August 9, 1939. It was a sub-contract made by Dowell.

The next agreement is between Dow Chemical Company and Robert J. Quinlan, dated December 24, 1936, and is in existence at the present time.

The Court

That makes three I have that are still in existence. A. Yes, that is correct. The Pure Oil Company, Dowell and Robert J. Quinlan.

The next agreement is between Dow Chemical Company and the Morgan Well Treating Corporation, dated January 1, 1937, and that agreement was cancelled, or, rather, it expired as of January 1, 1940.

The next agreement is between the Dow Chemical Company and the Big West Oil Company, of Montana, dated November 15, 1937; and it expired on November 15, 1939.

The next agreement is between Dow Chemical Company and Warren Hough, of Shelby, Montana, dated June 10, 1938, and that agreement is in existence.

The next agreement is dated August 31, 1938, between the Ainsworth Well Treating Service and Dow Chemical Company, and that agreement was cancelled as of January 1, 1940.

The next agreement is betweeen Dow Chemical Company and Pacific Cementing Company, dated September 2, 1938, and that was cancelled as of October 31, 1940.

The next agreement is between Dow Chemical Company and A. G. Chiles, of Hillsboro, Texas, dated May 23, 1939, and that agreement is in existence.

The next agreement is between the Dow Chemical Company and James G. Vander Grift, of Spencer, West Virginia, dated June 30, 1939, and that agreement is in existence.

I also have three agreements which are in existence, which were entered into in 1940. The first agreement is between Dow Chemical Company and Lane & Bowler Incorporated, dated April 24, 1940. The next one is between Dow Chemical Company and Charles Theo. Eline, dated May 28, 1940, and the next and last agreement is between Dow Chemical and International Cementers Inc., dated December 4, 1940.

I forgot to mention that there is one other agreement between Dow Chemical and Dowell Sociedad Anonima dated October 11, 1936, covering license rights in Mexico, a licensee and wholly owned subsidiary of Dow Chemical Company. That is still in existence. So, as a recapitulation, I have got nine existing agreements.

The Court:

Ten, counting this last one. Ten counting Dowell Incorporated, unless I have made a mistake. A. That is correct, Your Honor. I did not include Pure Oil Company. So including Pure Oil Company there are ten.

The Court:

Six have been issued and cancelled or expired.

CROSS EXAMINATION

By Mr. Lyon:

Q. In the Pure Oil Company agreement which is in effect between Dow Chemical Company and the Pure Oil Company, there is a provision to the effect that "Dow shall pay unto Pure a royalty of $5.00 for each and every well which shall be treated by Dow, its subsidiaries, sublicensees, agents and representatives, provided, however, that the royalty shall not apply to any wells treated by Pure." That is correct, isn't it? A. That is the way the agreement reads, yes, sir.

Q. As a matter of fact, the agreement between Dow and Pure was reached following a dispute between Pure and Dow as to the rights to the acidizing invention, was it not? A. This agreement that you just read from states that the contract of June 30, 1934, superseded and terminated the agreement dated January 31st, 1933.

Q. Well, the prior agreement of January, 1933, contained a provision that Dow shall pay Pure in the manner hereinafter specified a royalty of $5.00 for each and every well which will be treated by Dow, its subsidiary, and so forth, did it not, until the royalties so paid shall amount to $15,000? A. That is correct.

Q. There is no such limitation on the new agreement? A. You mean about the maximum amount?

Q. Yes. The present effective agreement. A. That is correct; yes.

Q. Well, now, these two agreements, one replaces the other and they are the only two agreements between Dow and Pure on this subject? A. There is really only one agreement between Dow and Pure because the latter one superseded the former one.

Q. Yes. Well, now, the agreement was made between Pure and Dow following a dispute between the two companies as to the rights of the acidizing invention, was it not? A. I didn't hear the latter part of that.

Q. Would you just read it.

The Court:

You refer now to the first agreement or the continuing agreement?

Mr. Lyon:

Oh, to the first agreement.

(The pending question was read by the reporter.) A. I know nothing of that. It was before my time, and I don't know whether it was true or not, of my own knowledge.

Q. When did you go with the Dow Company, Mr. Campbell? A. June, '35.

Q. June of 1935. Then you are not familiar or never heard of the letter addressed to the Pure Oil Company on November 1st, 1922—or 1932, by Mr. Willard Dow, and the Pure Oil Company's reply dated December 1st, 1932? A. I think I have seen that letter, and that is all. I know nothing about it.

Q. Could you identify those letters as letters in the company files? A. I cannot identify those letters, no.

Q. Did you negotiate either of these agreements between the Pure Oil Company and the Dow Chemical Company? A. No, sir.

Witness:

I referred to an agreement with the International Cementing Company, either the Dow Chemical Company or Dowell owns an interest in the International Cementing Company, or International Cementers, Inc. I am not sure which one it is. It is either Dow Chemical or Dowell that is a stockholder in that company, and I think it is Dowell. I am not sure what percentage. They are a substantial stockholder. One of the two, and I am not sure which it is. They were one of the incorporators and organizers of the company.

The only ones of these nine existing licensees outside of the Pure Oil Company in which either Dow Chemical or the Dowell have an interest are Dowell, Incorporated, Dowell Sociedad Anonima and International Cementers. That leaves six license agreements outstanding which are

held by concerns in which neither Dow nor Dowell hold any interest.

The Court:

(Interposing): What about Pure Oil?

Mr. Lyon:

That is excluded, your Honor. We have excluded that from this consideration.

So far as I know all those six concerns are actually operating under their license agreements and paying royalties at this time. The Accounting Department would know better as to whether they are actually paying royalties. They are actually actively employing the processes at this time. I know that of my own knowledge in each case.

These license agreements are not limited to the patents involved in this suit. They include other patents, too.

Q. I would like to know what patents those licenses are issued under. A. A typical example of a license is the A. G. Chiles license in which there are licensed fifteen patents, of which Dow Chemical is the owner. The licensee has also been granted license rights under two patents which Dow Chemical Company has a right to grant licenses.

Q. Does that include the Carr patent of the Pure Oil Company? A. That includes the two patents I am talking about which Dow Chemical has a right to grant sublicenses, Patent 1,891,667 and Patent 2,018,199, the first inventor being Carr and the second patent being Carr and Humphrey, inventors.

Q. Are the four patents involved in this suit of the Dow Company listed in these licenses, these six licenses, among those fifteen? A. Included in the fifteen patents in the Chiles license are the following four patents: 1,877,504, 1,916,122, 1,998,756, and 2,024,718, which I have been informed are the patents in suit.

Q. The licenses also cover eleven other issued patents by number? A. That is correct.

Q. Can you give us the numbers of those eleven other patents? A. Referring to the Chiles license, these are numbers 1,498,045; 1,911,446; 1,963,072; 1,989,479; 2,048,-

362; 2,503,285; 2,125,429; 2,127,662; 2,146,732; 2,146,754, and 2,152,306.

By Mr. Lyon:

Q. Continuing: Do you know whether or not those are all patents on various inventions relating to the acidizing of wells? A. That is correct. That is my understanding of them.

REDIRECT EXAMINATION

By Mr. Owen:

Q. You spoke of having rights to grant licenses under a Carr patent and under a Carr and Humphrey patent. And you also spoke of paying to the Pure Oil Company $5.00 a well royalty. Do those two things have any connection? A. The agreement with the Pure Oil Company, dated June 30, 1934, was a grant by Dow to Pure Oil Company of a non-exclusive license under 1,877,504. There was a reciprocal grant from Pure to Dow, a non-exclusive license with the right to sub-license others, under patent 1,891,667, and any other patents which Pure may acquire, own or control during the existence of this agreement and relating to the acid treatment of oil or gas wells for the full term or terms of any such patents.

The second sentence says: "Dow shall pay unto Pure a royalty of $5.00 for each and every well which shall be treated by Dow, its subsidiaries, sub-licensees, agents or representatives after the execution of this contract, provided, however, that such royalty shall not apply to any well treated by Pure."

RECROSS EXAMINATION

By Mr. Lyon:

Q. Under that agreement the Dow Company actually has paid a royalty to the Pure Oil Company on all acidizing jobs performed by the Dowell Company or Dow, and not simply on those performed using the Carr invention, isn't

that correct? A. That statement of yours is correct, with this proviso—that there was an amendment to that agreement, dated October 19, 1938, between Dow Chemical and Pure, reading as follows: "The royalty of $5.00 for each and every well which shall be treated by Dow, its subsidiaries, sub-licensees, agents or representatives shall apply only on acid treatments where the acid is used to attack a productive formation.

Q. Yes. In other words, the intent of the agreement as shown by what has been done in performing it is that Dow shall pay to Pure $5.00 on each acidizing job where the acidizing is to penetrate the formation. The payment of royalties is not limited to those jobs where Dow has employed the inventions of the Carr patents. A. That is correct.

CHARLES PENHALIGEN,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I live at Midland, Michigan, and am Treasurer of Dowell, Incorporated. I have been associated with that company over five years. My duties at first were as an accountant. On January, 29, 1937, I was elected Assistant Secretary and Auditor. On June 28, 1937, I was elected Assistant Treasurer. On June 5, 1940, I was made treas-

urer. The records of Dowell, Incorporated, are under my charge, or accessible to me.

Mr. Lyon:

We will concede, your Honor, that they have proper records, and that they will show royalties received from jobs done, and we will concede the competency of this witness to prepare a summary from the records, and if he produces a summary and says that it is correct to the best of his knowledge and belief, we will accept that without any further proof.

The Witness:

I have prepared a summary showing the growth of the Dowell business, both with respect to personnel and stations, as well as with respect to the locations in which the company operates, and the number of treatments made, which I produce.

Mr. Owen:

This enlarged chart, your Honor, which we will offer as PX-94, contains the data which this witness has prepared. I hand the court a reduced photostatic copy of that chart.

(The chart was thereupon marked PX-94.)

The Witness:

These are the Dowell, Incorporated, statistics for the period November 10, 1932, to December 31, 1940, inclusive, by years, and this reports the personnel, treating stations, pump trucks, compressor trucks, tank transports, tank trailers, pick-ups and passenger cars; the number of well treatments, and the number of states in which Dowell operated by years. The number of well treatments indicated on this chart do not include treatments made by licensees of Dowell, or of the Dow Company. Those are treatments that were made by Dowell Inc.

The portion of the chart which indicates the states in which Dowell operates indicates the order in which Dowell or Dow operated in these respective states. Michigan was the first, then Ohio and Kentucky. Those stations were all opened in 1932. Under 1933 we have those three states repeated and in addition Kansas, Louisiana, Oklahoma and

Texas, which means that stations in those four states were opened during 1933. That explanation follows all down through until in 1940 Dowell is operating in sixteen states. Dowell also operates outside of the United States, in Alberta, Canada. I think that Dowell operated in Ontario, Canada, starting in 1932 and started operations in Alberta, Canada, in 1937. The figures indicating the number of well treatments include those made in Ontario and Alberta.

We also have records showing the number of treatments made by licensees of Dow Chemical or of Dowell. I could prepare from those records a statement showing the number of treatments made by each of the different licensees by years, on which treatments those licensees paid royalties to Dow Chemical Company, and will do so. That statement will show the number of treatments by each licensee for each year during the period for which they have been licensed, and the amount of royalty paid by each licensee each year.

Mr. Owen:

I will ask the witness whether or not he knows the fact regarding the use of inhibited acid in the well treatments which he has listed in PX-94. A. It is my understanding that these wells were treated with inhibited hydrochloric acid.

Q. Will you refer to some invoices showing the use of the surface tension reducing agent? A. Yes, sir. I have a copy of a Dowell Incorporated invoice, dated July 7, 1934, billing the Continental Oil Company, of Borger, Texas, for one Dowell treatment, consisting of 875 gallons of Dowell X, and 150 gallons of XF. The X is 15 per cent inhibited hydrochloric acid, and F is surface tension agent, the reducing agent. When the letters "XF" are used together it indicates a combination of 15 per cent inhibited hydrochloric acid, and the surface tension reducing agent.

Mr. Lyon:

Is that the earliest date of an order that you could find showing the use of a surface tension reducing agent? A. I would not say it is the earliest, but it is one of the earliest.

The Court: What about the jelly seal? A. Well, jelly seal, I don't think was used until 1935, latter part of 1935.

Mr. Owen: Can you produce evidence or invoices showing an early instance when each of these different services was used? A. Yes, sir. I have invoice instructions here, dated November 23, 1932, on which we issued an invoice to the G. Lee P. Company, Midland, Michigan, for 1,000 gallons of Dowell X and 25 gallons Dowell blanket. It is my understanding that this was the calcium chloride blanket. I have here a warehouse shipment paper, which is instructions to the Invoice Department, dated December 1, 1932, to invoice H. P. Leeper for one Dowell service treatment, consisting of 500 gallons of Dowell X and 55 gallons of Dowell blanket.

I also have a copy of a Dowell Incorporated sales invoice, dated March 12, 1936, billing the Stanolind Oil & Gas Company, Tulsa, Oklahoma, for Dowell jelly seal, base service charge of $25.00 and Dowell jelly seal used in addition, 169 gallons, at 50c a gallon, $84.50, and this invoice is sup-

CROSS EXAMINATION

By Mr. Lyon:

Q. I believe you have some printed schedule of the different compounds or agents that are employed by your company in acidizing the wells, that is the agents that are added to the acids, by a series of letters? A. Yes, sir.

Q. Will you just read me that schedule? I mean, what different letters are employed and what each one of the letters stands for?

Mr. Owen:

I object to that, Your Honor, if it refers to materials other than those involved in the practice of the inventions of the four patents in suit. I can't see what relevancy it can have.

Mr. Lyon:

I want to say, Your Honor, that these treatments which are involved in this summary, Exhibit 94, include a lot of different features that are covered by patents which are not involved in this suit, so as to show that those treatments are in part based on other things that are not involved in this suit.

The Court:

I don't see any way of avoiding that. You show very properly the growth by the use of these patents but your own table shows that other patents are used along with these. Now, right as I set here right now, you see, I have no way of knowing how much that growth is due to the patents in suit, and each one of the patents in suit, or as between the patents in suit and this larger number of patents that were included there than are in suit.

Mr. Owen:

Yes; that is true.

The Court:

Now, the same chart could be used almost in a suit based on some of those other patents not in suit, you see, and I am confronted with a situation where I don't see how to avoid that inquiry being made as to what this is.

By Mr. Owen:

Possibly this would avoid the difficulty that I am in. As I understand it, our client is not anxious to disclose its code numbers for different treatments to its competitor, the defendant in this case. I will ask the witness to state what information he would be able to give on the subject of what different ingredients were used in these treatments which are indicated on PX-94 from an examination of the invoices or other records which you have under your control without disclosing the code number which is used by Dowell Incorporated to designate these different ingredients. A. The customer receives the information as to XX and jelly seal and W's and F's, but I don't know what the chemicals are that are used in these,—the names of these chemicals. I am not a chemist.

Mr. Lyon:

Let me ask him this question. I don't think you will object to this. Under these code numbers can you tell us about how many different things there are that are added to this acid or used in this acidizing? Do you have a schedule there of the code numbers and each code number is a different thing? If you just tell us how many of those there are, that will be a start? A. Well, I have before me a Dowell Incorporated acidizing service price schedule.

Q. And how many different items are there as indicated by different code numbers there? A. Well, it reports Dowell X, XF, XG, XR, XW and XX.

The Court:

Six.

Mr. Lyon:

Q. And which of them relate to the four patents in suit? A. I don't know what the patents are.

Q. You looked at something else. A. I referred to this book here (indicating) X, XF, XG—

Mr. Lyon:

How many are on there? A. Seven.

Q. Well, you might give all of those seven. A. Dowell X is inhibited hydrochloric solution. Dowell F is

a surface tension reducing agent for use in tight or low pressure wells. Dowell G, foaming agent for use in limestone removal. Dowell W, agent which imparts emulsion prevention and wetting properties to the acid. Dowell XX, intensifying agents for use in Dolomite formations. Dowell XR, retarding agents for use in fast action limestone formations. Dowell XW, mixture of highly active acids capable of dissolving Bentonite types of mud.

Q. Now, are you able to state whether or not the total well treatments indicated on Plaintiff's Exhibit 94 contained inhibited acid? A. Yes, sir.

Q. Or rather involve the use of inhibited acid? A. Yes, sir.

The Court:

All of them? A. Yes, sir.

The Court:

I am suggesting a chart that would show wells treated with inhibited acid and nothing else. I don't know what it would show. It certainly wouldn't show the growth here, because you have got those wells as well as these using the new fangled stuff. A. True.

By Mr. Lyon:

Q. I just want the court to see the form of the Dowell invoices. This is a typical form, isn't it? (Indicating.) A. Yes, sir.

Mr. Lyon:

This is an invoice dated 3/16/36 to the Stanolin Oil and Gas Company, and the following description and prices appear on the invoice:

"Acid L. L. Austin No. 36 Well Section 36 12 16 Ellis County Kansas with 1,000 gallons of Dowell X and other materials, unit price $225. Additional Dowell X used 2,000 gallons at 20 cents per gallon, unit price $400. Additional for using Dowell jelly seal, base service charge $25. Dowell jelly seal used, 150 gallons at 50 cents per gallon, $75. Total $725. Less 20 per cent contract discount, $145. Amount $580."

Q. Now, where these different items, of which you have given us the code numbers, were used in the service or in the treatment, they would be identified and itemized charges for those would appear, for those individual items appearing on the invoice, would there not? A. Yes, sir.

Q. Do these well treatments that are tabulated in the summary, Exhibit 94, include anything except acidizing jobs? A. No, sir.

Q. Do you know whether these well treatments up here that are summarized on Exhibit 94 include mud treatment jobs that have been done by your company? A. Well, if we used inhibited hydrochloric acid, it is included. I don't know what the technique is on the mud acid. I don't know whether they use hydrochloric acid or some other acid. I do not know what is meant by "mudding off" a well. I know we have a mud acid service. I would have to go back to the records to tell whether or not that includes hydrochloric acid.

These figures on Exhibit 94 include jobs in California. I don't know that the only service that our company performs in California is this mud dissolving, and that there is no acidizing of formations in California. At the present time we are not in California. We were in '40. I don't know that we never did acidize formations in California. I don't know one way or the other. These figures may include services performed by our company which are not acidizing formations, as far as I know. Those figures include sales invoices we have on hand that indicate we acidized the wells, using 15%—or use inhibited hydrochloric acid. Every one of these treatments included in the summary, Exhibit 94, did employ hydrochloric acid. I don't know what hydrochloric acid was employed in the jobs in California that are indicated on Exhibit 94. I don't know of the exact application. I don't know whether they were for treating formations to increase the productivity. I do know that we have a mud service operation. As to whether the jobs in California were the mud service operation or the treatment of formations, it would be necessary for me to review our records.

WILLIAM F. BROWN,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I live at Mt. Pleasant, Michigan, and am a consulting geologist. I received a Bachelor of Science degree from the University of Michigan in 1925 and spent a year on graduate work at the University of Wisconsin in 1926. After finishing college I worked for the Michigan State Conservation Department, The Pure Oil Company and the Cities Service Company, and since 1931 have been a consulting geologist in Michigan.

Referring to the article in the August 29, 1932, issue of the "Oil Weekly" (PX-14) relating to the Walter L. McClanahan Inc.'s Schaeffer No. 1 oil well located in Midland County, Michigan, I have examined the State production records for this well at the office of the Michigan Tax Commission for the period from July 14, 1932, the completion date of the well, to June, 1936, the date when the well was abandoned. These records are sworn statements made by the oil operator to the State of Michigan Tax Commission and are open to the inspection of the public and show that this well was completed July 14, 1932, during which month it produced a daily average of 75 barrels of oil. After being acidized, it had a daily average production of 334 barrels for August, 374 barrels for September and 234 barrels for October of 1932.

I also examined the records of the Michigan State Tax Commission and Michigan Department of Conservation concerning T. K. Buzzard's Mahon No. 1 well, referred to in the November 14, 1932, issue of the Oil Weekly (PX-14). These records showed that this well produced 381 barrels of oil in January, 1932, 538 barrels in February, and 58 barrels in March, was plugged and abandoned on March 12, 1932; reopened in October, 1932, and treated with acid, and in November, 1932, it produced 2,017 barrels of oil, and in December 2,020 barrels of oil. The well was finally plugged and abandoned in 1936.

I examined the records of the geological division of the Michigan State Conservation Department concerning the oil wells in the Greendale Oil Field, Midland County, Michigan, and from them made a compilation covering the years 1932 to 1940, showing each year the number of oil wells completed, the number of dry holes, the number of wells shot (dynamited) at completion of the well drilling, and the number of wells treated with acid at completion. This compilation shows that from 1928 to 1932 the number of wells drilled in this oil field increased, and that from 1932 to 1940 the number of new wells declined. The top number of new wells completed in any year was 98 in 1932. During that year seven dry holes were drilled, three wells were shot at completion and eight were acidized. The compilation shows a decrease in the number of wells shot at completion and an increase in the number of wells acidized at completion.

The compilation was offered as PX-99, and is as follows:

COMPLETION DATA GREENDALE OIL FIELD
Greendale Twp., Midland County, Michigan

Year	Oil Wells Completed	Dry Holes	Wells Shot at completion	Wells acidized at completion date
1928	3	0	1	0
1929	11	2	0	0
1930	17	0	0	0
1931	26	3	1	0
1932	98	7	3	8
1933	53	8	0	4
1934	19	1	0	4
1935	14	3	0	11
1936	13	2	0	13
1937	6	3	0	6
1938	0	0	0	0
1939	1	0	0	1
1940	1	0	0	1

CROSS EXAMINATION

By Mr. Lyon:

Q. This PX-14 and the data you presented a moment ago refer to the well known as T. K. Buzard's Mahon 1 Isabella County, Isabella Township, Section 24? A. Yes.

Q. You know that well? A. Yes.

Q. Do you know who acidized it? A. No.

Q. Do you know whether Dow or Dowell acidized it? A. No.

Q. I show you acidizing order to the Halliburton Oil Well Cementing Company, from Petroleum Investors, Inc. with respect to Knight Well No. 2, Section 16, Township 18 N, Range 1 East, dated 4-24-39, signed by William F. Brown. Is that your signature? A. It is.

Q. By what authority did you sign that order on behalf of Petroleum Investors, Inc.? Were you connected with Petroleum Investors, Inc., at that time? A. I have done considerable consultiing work for them, yes.

Q. I have asked you the question, were you employed by them at that time? A. Not as a member of the firm.

Q. What authority did you have to sign an order, an acidizing order to the Halliburton Company on behalf of Petroleum Investors, Inc., at that time? A. I asked them for a letter giving me permission to acidize that well, and to be present and observe, and take samples on the well at the time it was acidized.

Q. Why didn't you sign the order in your own name, on behalf of yourself, if you were doing the work—if you were having the work done for yourself? A. It wasn't my well.

Q. I show you a letter on the stationery of William F. Brown, Petroleum Geologist, Mt. Pleasant, Michigan, dated April 19, 1939, addressed to the Petroleum Investors, Inc., and Doherty & Markay, Inc., Olympia Building, Mt. Pleasant, Michigan.

(Reading): "Gentlemen: Since I am desirous of ob-

taining certain acid treatment information for a client, and since you are desirous of having a well treated, I agree to pay to you the full charges made by the acid treating company for the treatment of the Knight No. 2 well, located in the SW¼ of Section 16, Hay Township, Gladwin County, Michigan.

"The conditions which I require are:

"That I choose either Dowell or Halliburton Company to do the work, specify the type of treatment, and be present during the full operations of treatment.

"Also, I shall require average daily production figures for ten days before and ten days after treatment.

"If the above arrangement will be satisfactory to you, please denote your approval below.

"Very truly yours,

"William F. Brown."

Is that your signature? A. Yes, sir, it is.

Q. Did you send that letter to the Petroleum Investors, Inc., under the date of April 19, 1939? A. I did.

Q. Who was the client referred to in this letter for whom you desired the information? A. The Dow Chemical Company.

Q. Were you authorized by the Dow Chemical Company to enter into this agreement with Petroleum Investors, Inc., whereby you could require that the Halliburton Company acidize this well of the Petroleum Investors, Inc.? A. They asked me to get certain information and to do it in the way that I wanted to.

Q. Did you reimburse Petroleum Investors, Inc., for the Halliburton Company charges for that job? A. I did.

Q. Was that money paid to you, supplied to you by Dow? A. It was.

Q. Well, now, were you present at the acidizing of that well by the Halliburton Company? A. I was.

Q. Did you pose as an employee of the Petroleum Investors, Inc.? A. I did not. It was not necessary to do so. I was merely present at the acid work.

Q. In what capacity did you advise the Halliburton representative that you were attending that job—in any? A. I don't believe they asked.

Q. You signed this order? A. If they had asked me, I would probably have said that I was doing it for myself.

Q. Where were you when you signed this order? A. At the well.

Q. You were at the well? A. Yes.

Q. How did they come to ask you to sign the order? A. Because I ordered the acid. I was there at the complete treatment, and supervised the treatment from beginning to end.

Q. You do not deny that you posed as a representative of Petroleum Investors, Inc., do you? A. No.

Q. You did not advise the Halliburton Company that you were representing the Dow Company? A. I did not.

Q. Did you specify any of the conditions under which the well should be treated? A. I did.

Q. Did you specify that inhibited acid be used? A. I did not.

Q. What other directions did you give? A. The main directions were to put 1500 gallons of acid in the well, and to put a blanket at the bottom of the tube, and to flush it.

Q. What kind of a blanket? A. Blanket seal.

Q. What kind? A. I didn't specify. They were to use their own blanket. Then the tubing was to be flushed with oil. That is about all the instructions I gave them. Otherwise, they were to use their own regular methods of acid treatment.

Q. Did you give them these instructions in writing? A. No.

Q. Did you specify that oil would be pumped into the well first, before the acid? A. Well, we were trying to get circulation from the tanks.

Q. Did you specify? A. Did I specify?

Q. Yes? A. I don't remember whether I did or not. I doubt it.

Q. Do you remember that the oil was pumped into it? A. Yes, oil was pumped in.

Q. Down the tubing? A. Yes.

Q. And tried to establish circulation in that way? A. Yes.

Q. Before your acid was put in the tubing? A. It was not to establish circulation. It was more to get oil coming from the tanks. We got some oil down the hole. The tanks were setting on top of the hill, and the oil pumps were connected to the tanks, and we intended getting some oil into the tubing.

Q. You wanted to fill the tubing? A. No, we couldn't fill the tubing at that time. We didn't—you mean before the blanket or before the acid?

Q. Before the acid? A. Yes, we tried to establish circulation at that time. You are correct.

Q. And you filled the inside of the tubing and the outside of the tubing? A. We couldn't get circulation with the oil.

Q. How far did you get the oil to come back up outside the tubing? A. We put in 90 barrels of oil, or I should say Halliburton pumped in 90 barrels of oil and he couldn't fill the tubing, so Mr. King, who was supervising the acid work, stopped putting the oil in, because we couldn't establish circulation. There was no use pumping any further in. We only had about a hundred barrel on hand in the tanks.

Q. What equipment did you use in handling that oil and introducing it into the tubing? A. Halliburton's equipment.

Q. It ran through the Halliburton equipment? A. Yes.

Q. At your request? A. Yes.

Q. That was Michigan oil in those tanks, was it not? A. Yes, sir.

Q. Do you know whether or not Michigan oil contains mercaptans? A. No.

Q. You know what mercaptans are? A. No.

Q. Do you know whether Michigan oil has a characteristic odor? A. A what?

Q. A characteristic odor, strong odor? A. Some oil has stronger than others.

Q. Well, did this oil have an odor? A. Buck oil is always quite a sweet oil.

Q. Did it have an odor? A. I could tell it was oil, crude oil, by its odor.

Q. Did it have one of these bad smells, that some of these Michigan oils have? A. No.

Q. Did you try it to see? A. I have seen a lot of it, and I don't remember that that particular well had any sour oil.

Q. You don't remember whether it did or not? A. No.

Q. Did you request that that oil be handled through the Halliburton pumps or the Halliburton equipment? A. I did not request directly, no. I asked them to give me an acid treatment in their regular way. I assumed that they would use their equipment.

Q. Didn't you ask that they pump that oil into the well or into the tubing through their pumps? A. Yes, I believe I at least conferred with them on it. I don't remember our conversation.

Q. And that oil went through that system before the acid went through the same system, did it not? A. Through the pumps?

Q. Yes? A. Yes.

Q. And when the acid was handled by those pumps, it was discharged into what? A. Into the Halliburton pumps.

Q. From the tanks? A. From the tanks.

Q. On the trucks? A. On the truck, into the pump, Halliburton pump, into the well and tubing.

REDIRECT EXAMINATION

By Mr. Conner:

Q. You live in Mt. Pleasant, do you not, Mr. Brown? A. I do.

Q. How long have you lived there? A. Since 1932.

Q. How long have you known, if at all, that Halliburton Oil Well Cementing Company have a place of business in Mt. Pleasant? A. I believe it was 1934, when I first knew the Halliburton men themselves. I think they had some equipment in before that, but I wouldn't be too sure about it. I think it was 1934 when I first—

Q. (interposing): What is your present knowledge as to the business that Halliburton transacts out of its station in Mt. Pleasant, Michigan? A. Well, I see the trucks there.

Mr. Lyon: At the present time? A. And equipment.

Mr. Lyon: There is not involved anything subsequent to the filing of this bill.

Mr. Conner: How long have you known that Halliburton in Mt. Pleasant was in the business of acidizing wells? A. I believe that was in 1934.

Q. You come in contact a great deal with operators in your work, petroleum operators, do you not? A. I do.

Q. Is it not common knowledge among those operators that Halliburton Oil Well Cementing Company operates a station at Mt. Pleasant, Michigan, and their business is acidizing oil wells? A. Yes.

Q. Is it common knowledge that Halliburton would supply the acid? A. Yes.

Q. Supply the blanket? A. Yes.

Q. Supply the surface tension reducing agent? A. Yes.

Q. Now, when such services and materials are supplied, who actually furnishes the equipment with which those materials are put into the well? A. Halliburton Oil Well Cementing Company.

Q. Now, does the operator in any instance ever supply the pumps or equipment for putting those materials in the well? A. Not that I know of.

Q. I would like to have you tell the court this: In this particular treatment of this Knight well for the Petroleum Investors, the Halliburton treatment of April 24, in the year 1939, I believe, is it not— A. That is right.

Q. —did Halliburton have any way of knowing that the Dow Chemical Company was to ultimately pay for that treatment? A. Not that I know of.

Q. You didn't tell Halliburton? A. No.

Q. That Dow would ultimately pay? A. No, I didn't.

Q. Then, in this instance, perhaps you can tell us wherein the services that Halliburton rendered to the Petroleum Investors was any different than that which it would have rendered to any other operator?

Mr. Lyon (interposing): I object to that. A. I don't believe there was any difference.

Mr. Lyon: I object to that on the ground it is only within the extent of the witness's notion what their service is that he can answer.

The Court: Well, you don't claim it was any different, do you?

Mr. Lyon: Between what?

The Court: Well—

Mr. Lyon (interposing): I don't know what they are going to claim for this.

The Court: What they claim is that you treated them like anybody else over in that district, as I understand it. That is what you want?

Mr. Conner: What I am trying to show, Your Honor, is that Halliburton is in the business of acidizing oil wells, and they have equipment. They offer acid, they offer pumps, they offer surface tension, and you call them up to treat your well and they treat it the same as if I called them up. There was nothing any different because they treated this well for which we were forced to pay in order to have a man present, Mr. Brown, for the purpose of taking

samples. There was no difference in the way it was treated.

The Court: What you want to prove is that is the way you know it was treated, and you want to show that that is their usual way of treating wells.

Mr. Conner: It is so far as we know, and I think it is up to them to show it was different, if it was.

The Court: Well, that is something particularly within your knowledge, and I will let them prove it in a pretty slip-shod sort of a way.

Mr. Lyon: That is quite all right.

The Court: Because it is so easy for you to dispute.

Mr. Lyon: We may agree, Your Honor.

The Court: I thought probably—

Mr. Lyon (interposing): That there was no difference, but I want to know what they are going to say they found in these samples and what they attribute what they found to before we agree that that well was done under this witness's direction and is typical of the wells that we do in Michigan.

The Court: Well, so far as their proving it, but you don't want them to get in that that was typical until you know what they claim was in there.

Mr. Lyon: That is right.

The Court: I think you are quite right in that reservation, and I hadn't covered that phase of it. So far as his observation goes, the treatment of this was the same as any other, but he hasn't covered those items concerning which they say they might want to object. That is when you get down to the analyses.

PAUL E. FITZGERALD,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I live in Tulsa, Oklahoma, and am employed as a geologist by Dowell, Inc. I have a degree in geology from Ohio State University, have done graduate work at the University of Michigan and have been employed by Dowell since 1933. Upon leaving the University of Michigan I taught school and later worked for the Pure Oil Company as a geologist. The most important of my present duties is keeping up with developments in the various oil fields throughout the country wherein the services of Dowell Incorporated might be applicable.

I have made a study concerning the limestone well producing fields of the United States with reference to the date in which the various limestone fields in the various well producing states were discovered. This study was completed within the last thirty days. It was begun about the first week in July, 1941. It was made, according to my understanding, for the purposes of this suit. The survey is in two sections. The first section contains three parts. Part 1, or Sub-1 of the first section of the report lists the earliest limestone discoveries in the various fields throughout the United States. We give the location and the name of the field and its date of discovery. Part 2, or Sub-2 of Section 1 of the report, indicates the approximate number of fields producing oil from limestones that were discovered prior to 1932, and Part 3 shows the approximate number of the oil companies that were known to be operating in these limestone fields prior to 1932.

Section 2 of the report lists the states and shows the names of the companies that were operating in the states in fields that were discovered prior to 1932. These are limestone fields, you understand. It also shows the num-

ber of well treatments that have been made for these various companies. This doesn't mean that these companies were operating in the state prior to '32—it only means they were operating in fields producing oil from limestone that were discovered prior to 1932.

(Here the report was offered and admitted as PX-192.)

Mr. Lyon: I object to the report and its offer as being hearsay in character. There has been no foundation for it at all as to its character, what weight can be given to it or whether it is admissible at all.

The Court: I recognize the importance of that. Your people are experienced in this, familiar with it, and if you find a few defects in it, bring it to my attention.

The Witness: The information included as part of the report, Subs. 1 and 2, which list the names of fields. That part of the report is a matter of record. There are various publications from which that information can be obtained. It is merely a historical statement of the name of the field, its location and its date of discovery.

The Court: Now, the other side can check that.

Mr. Conner: Yes, your Honor.

The Witness: The information in part 1, as to the names, locations, and time of discovery of the fields, is a matter of record. Sub. 2, or the part that has to do with the number of limestone fields that are producing in these various states, or were producing in them prior to 1932, is also a matter of record. It is published data, that is, information that is available in any publication that has to do with the history of the oil producing industry.

With regard to Part 3 of the report, that information has been secured through our various district managers and engineers throughout the areas in which we operate. We have listed in this section of the report the approximate number of companies that were known to be operating in these various fields prior to 1932. The list is not complete, because in some cases we have no way of checking exactly the names of all the companies that were operating. However, we are quite confident that the names that are listed

in my report are correct, and this is intended only to show the more important operators.

The Court: What do I understand you to mean by that word "state," where it says, names of some companies that operated in the state prior to 1932.

Mr. Conner: If your Honor will look at the top of the page, this first page refers to Ohio, and in Ohio he gives you the limestone fields, and the date of their discovery in Ohio.

The Witness: If you will follow the report as I go through it you will find under "I" the first limestone fields, and I have listed them. The first one is the Lima, Ohio, field. It is located in Northwestern Ohio, and it occupies a large number of counties. That field was discovered in 1885. The producing formation is the Trenton limestone. The next field that I have listed here, and it is not a very important field, is the Newburg field which is in Northeastern Ohio, south of Cleveland, and it produces from the Newburg limestone and was discovered about 1915. I haven't taken the trouble to list the other limestone fields which are known to be producing and all prior to 1932. There weren't many important limestone fields in Ohio, outside of the Trenton field in Northwestern Ohio.

The Court: This is explanatory to me, since I have found out about that.

Witness: Now, there are no, as I said previously, no records of the exact number of operators that were in these fields prior to 1932, but we do know that prior to 1932 the companies listed below were known to have operated some of the important ones: Pure Oil Company, East Ohio Gas Company, Ohio Fuel Supply Company, Ohio Oil Company, and Sun Oil Company, and many others.

The next page. The next state in which oil was found in limestone is Indiana, and here we show the same outline, and again we find that the first field was the Trenton field in Northeastern Indiana, occupying several counties. It was discovered in 1886. And the next limestone discovery in Indiana was in 1893 when another limestone was discov-

ered in Decatur County. We find from the record that there were approximately eleven limestone fields in Indiana prior to 1932, and our record of the number of companies operating in these fields prior to 1932 was only four, and among these are the Ohio Oil Company and the Siosi Oil Company.

The next state in which oil was discovered from limestone was Kansas, and that would be the third page in this report. We find that the first production of oil or gas from the limestone in Kansas was in 1888 when the Lyons gas field in Rice county was opened. The next limestone field in Kansas was the little Dexter field of Cowley County which was opened in 1903. In 1917 the famous Eldorado field of Butler County was discovered. Our records or the records that are available indicate that there were 78 limestone producing fields in Kansas prior to 1932.

The Court: Now, I notice that he is simply reading from this, which is apparent. I wonder if we couldn't save time, if there is nothing more only to do that with him, I would suggest that we let Mr. Lyon ask him any questions he wants to before night, and then have it over night to use.

Mr. Conner: There is a second part to this report which I think needs some explanation, and if Mr. Fitzgerald will explain it, why, perhaps we will not have to go through each state.

The Court: All right.

The second section of the report, beginning at page 20, lists the states and the companies in those states for whom we have acid treated wells. And these companies were operating in fields that were discovered prior to 1932. If you will take the first page of this section of the report you will notice there are three states listed, and you will notice that in Illinois we treated 99 wells. You will notice that in Illinois we have listed three companies and a miscellaneous group, and the total number of wells that were treated is 99. These wells have all been treated by Dowell Incorporated.

Q. And is it your statement that these companies here listed and under each state are operating in fields which are

limestone fields and which were discovered prior to 1932? A. That is right.

Q. And that is true all the way through the rest of this report? A. That is right.

The Court: And these number of wells have been treated during what period? A. Since 1932 up to the end of 1940.

For Indiana there were only 91. And in Kansas there are two pages here, but that total was 731 for Kansas. In Kentucky there were 123. Louisiana 1319. Michigan 763. New Mexico 323. Oklahoma 2293. Ohio 155. West Texas 943. North Central Texas 104. Texas Panhandle 417. The South Texas area, that is the Balgoni's Fall area, 154. Or a total for all of Texas of 1618. There were 349 treatments made in Montana and 80 treatments made in Wyoming.

Mr. Lyon interposing: Only one thing I would like to know before we adjourn, if you can tell me whether or not he has got some appendix or supplemental information to this report that shows where these different items of information came from, that I can check against the report and shorten any questions we have about it. For instance, how do you know that the Bell & Scholl Company, Item C on the first page of this report, was in business prior to 1932? How do you know that? A. Well, because I know the company and I know that they operated in Ohio prior to 1932. I do not know every one of these companies on this report. In the case of Ohio, I know all of those companies operated there. As a matter of fact, I grew up in Ohio. I did not know them before 1932.

Mr. Lyon: Well, then, what is the source of your information that they were operating in Ohio before 1932? A. I told you a while ago that I made the statement that this report was worked up in part by our district managers and our treating engineers in the field, and part of this report was compiled by them. Their original reports are available here in this city. Such work as appears in this report that I personally did not do was done under my

supervision, and I have reports from the men in the field to me which include the other data in these reports.

Mr. Lyon: Do those reports show where the other men got the data? A. No, I don't think they do, completely.

The Court: I am admitting this. I say, I am going to admit it, and the weight that I give to it will depend somewhat on what I find out about the regularity of it later on. But I am letting it in now, tonight, in order that the defendant may look it over; and I will, before I am through, find out how much they know, and what they do not know about it, and if there is anything—well, it seems that if it is pretty bad, they should have something that would show what is absolutely wrong with it, and if they—your proof to support it is so weak, and I recognize that it would cost a fortune, and take more time than I would give you to prove all that is in it, to hold you to strict evidence; so I am going to do that, but I am letting it in, and giving them a chance to dispute it, and if they do not dispute a single item, I will think that it is pretty well prepared. If they find some things in there that are wrong, I will hear about it.

The Witness: While employed by Dowell Incorporated I have engaged in the actual treatment of oil wells with acid. That work was begun in March of 1934 and later in 1934 I was sent to the Rocky Mountain area where I opened a treating station at Shelby, Montana. I was located there as a treating engineer and district manager until the close of 1934, when I was transferred back to Michigan. During that time we treated wells in the various oil fields in Montana, which included Kevin, Sun Burst, and Pondera, these fields being located near Shelby.

I have made a particular study of many fields in Montana to show the effects of acidizing. I was interested in the possible effects of acidizing on limestone and its effect on the recovery of oil and in that connection I became interested in this small Pondera oil field, which at the time when I was there had about 154 wells in it, and the field was not being pro rated. Dowell was doing all of the acidizing and it was quite easy to secure production information. In that

connection, after my return to Michigan in December of 1934, in February of 1935 I began to make a more serious study of this field, and wrote a letter to the Stanolind Oil and Gas Company at Casper. This letter was directed to Mr. John Evans who was their petroleum engineer in the Rocky Mountain area at that time. I requested from him information relative to the effect of acidizing on their wells. I have a letter from Mr. Evans in reply, written February 19, 1935. I shall quote one paragraph from this letter:

"Acid treating on our leases in this field—" Mr. Evans is referring to the Pondera field. "—has been very profitable and has, I am satisfied, materially increased the ultimate production to be expected from those leases. The best evidence that this is true is that the wells making around a barrel per day prior to acid treatment were increased up to ten or fifteen barrels per day by the treatment and are still maintaining this increased production some six months later. Nine wells were very near their economic limit and could not have been expected to produce much more oil before being abandoned had they not been acidized."

About a year later, as a matter of fact it is more than a year later, it was in June—May 29, 1936, I wrote a letter to Mr. Evans' successor, Mr. N. P. Huntington at Casper requesting later data and more complete information on the effect of acidizing in this Pondera field. More than a year had passed, and I was anxious to know whether these wells were holding up, and Mr. Huntington replied on June 2nd, and I shall quote one paragraph:

"To provide a picture reflecting the answers to your three questions I am attaching a sketch representing the production from our Pondera property. We operate forty-seven wells there. I estimate that acidizing has directly resulted in 80,000 barrels of oil to date, and that our ultimate recovery has thereby been increased 250,000 barrels. This latter figure is of course more in the nature of a guess than an estimate."

The Court: What were the three questions? A. I will read the paragraph in which I stated the questions. "I am

wondering, therefore, if it would be unethical to ask you to write me a letter outlining in a general way some of the data that you may have regarding the value of acidizing in Pondera. That is—(1) How much has the ultimate recovery of your producing properties been increased by the intelligent use of acid; (2) how much oil has been recovered as a direct result of acidizing, and (3) what is the present production as compared to production before treatment."

The Court: All right. Now read the other. A. He says: "I am attaching a sketch representing the production from our Pondera property. We operate forty-seven wells there. I estimate that acidizing has directly resulted in 80,000 barrels of oil to date, and that our ultimate recovery has thereby been increased 250,000 barrels. This latter figure is of course more in the nature of a guess than of an estimate." Then Mr. Huntington attached this curve or graph to his letter. This graph is merely a decline curve of their properties in the Pondera, beginning with 1931, extending to 1935, and it shows the production in barrels per day, and it shows acidizing in 1934, and it shows there was a change in the direction of the curve, indicating more oil was being produced following acidizing than there was before. The new curve is about a year and a quarter old. The difference between the old curve and the new curve, according to Mr. Huntington, represents an actual increase in production of 80,000 barrels for that period and that if they extend the new curve out from the point where it intersects the old curve, they will get approximately 250,000 more barrels than they would have if they had not acidized the wells.

The Court: When does the curve start? A. At the beginning of 1934 when three wells were acidized.

The Court: January 1st. A. It wasn't that early. I can't tell from this, exactly. I should say probably February, 1934—that is when 3 wells were treated, and about July or August of '34 they treated 20 additional wells.

The Court: It began what time, then, the first one? A. The first three wells were probably treated in Febru-

ary of '34, and the additional 20 wells were probably treated in July or August of the same year.

Mr. Conner: I offer the curve referred to as PX-193, together with the letters explaining the same.

The Witness: These figures on the Pondera field in Montana with respect to production of oil from the field which I have given are production figures I got from someone else as the source. I have myself made a survey or study of the production of this field, which is reflected in the chart I have in my hand.

Mr. Conner: I offer the chart as PX-194.

Witness continuing: This chart is a decline curve of the entire Pondera oil field and it is nothing more or less than the plotting of the production data by months for the total field. I began my curve in January '33 and I kept it up to November, 1937. The curve shows, beginning in January '33, they were producing approximately 32,000 barrels per month, and that there was a gradual decline from that time down to July of 1934, when they were producing about 28,000 barrels per month. Acidizing in the field was begun in July—July 28, 1934, and there was an immediate increase in production. You must understand that during this period no new wells were drilled, so that the change in the direction of the curve must be attributed to acidizing.

Q. During which period is that you refer to? A. From the time the acidizing was begun in July of 1934. This curve moved upward very rapidly beginning in September, 1934, and in October of '34 the field was producing 34,000 barrels. In December it was producing approximately 41,500, and then the curve bobs around quite considerably. There is a big drop. There were 154 wells in the field in all. I don't know exactly when the last producing well was drilled in this field because there were no wells drilled in the field that were commercial producers during the time I was there. So I think the last producing well was drilled somewhere in the latter part of '33. I do know there were no new wells drilled during the period I was there. There were dry holes all around this little field.

Q. And yet this curve show there was more oil produced after 1934 as a result of acidizing than there was oil produced in 1933? A. That is right.

The data on this report shown in the little boxes down at the bottom, for example, 1933, show 351,099 barrels. These figures came from the Oil Conservation Board of Montana. I have here a certified copy of a statement of the crude oil produced and refined in Montana by fields from the discovery date to June 30, 1939.

Mr. Conner: I would like to offer in evidence as PX-195, the Montana Oil and Mining Journal of Saturday, January 26, 1935.

(The document above referred to was thereupon marked Plaintiff's Exhibit No. 195.)

Mr. Lyon: May we have an understanding that in objecting to the witness' summary of his report, PX-192, that that applies to these other exhibits without being repeated.

The Court: Yes, it may.

Mr. Lyon: I mean exhibits that he is introducing with reference to that matter. The exhibit that I refer to is this large report of his.

The Court: It is of that type and your objection will apply to it.

Mr. Conner: This article, PX-195, is with reference to this same field and pool at Pondera, Montana, and the article states:

"Pondera production up 22,000 barrels.

"Use of acid boosts field production total 3,675,391 barrels.

"With no new drilling, Pondera oil field increased its production during 1934 by 22,210 barrels over 1933 according to official production figures compiled in the office of the Petroleum Conservation Board.

"This increase in production was due to the use of acid on the lime formation in these wells, chiefly during the latter part of the year.

"The 1934 production brings the total yield of the field up to 3,673,391.74, which has been marketed for slightly more than $3,000,000."

Q. Now, Mr. Fitzgerald, might I ask you, do you have in your possession any publications or releases or data from the Oil Conservation Board of the State of Montana which mentions acidizing? A. I have in my hand Bulletin S-1, dated November 13, 1936, published by the Oil Conservation Board of the State of Montana. This is a certified copy signed by R. P. Jackson, Secretary of the Oil Conservation Board of the State of Montana. On page 20 of this report there is a statement regarding the use of acid in Montana oil fields. I shall read this short statement.

I had nothing to do with the writing of this article and do not know who did write it. I first saw it about ten days ago, and never heard of it before. The title of the article is "Acidization." It reads:

"The treatment of zones in the Ellis-Madison contact horizon showing oil in newly drilled wells, as well as old 'stripper' and apparently exhausted wells, with hydrochloric acid compounds of various kinds has been generally most amazingly effective in stimulating oil and gas production. This is especially true in the Kevin-Sunburst field, where most of the acidation work has been done. The first record of acidizing operations appears in 1933 and from that time to December 31, 1935, the records show that 464 of the 980 producing, or 'shut-in,' wells in the Kevin-Sunburst field have been acidized, one time or more. Acid treatment of newly drilled wells apparently non-commercial converted them into prolific oil producers in most cases. Applied to old, and apparently exhausted, wells, it revived them and sometimes increased production to a level never before reached. In comparatively few instances have the results of acid treatment been disappointing to the operator. It may be noted in statistical table '1-A' that since acid treatment of wells in Kevin-Sunburst field was commenced in 1933, out of the total 84 new wells drilled during 1933, 1934, and 1935, only 15 were abandoned as initially

dry or non-commercial, that is, slightly less than 18 per cent, whereas during the years 1922 to 1932, inclusive, out of total 1528 wells drilled, 399 were abandoned as initially dry, that is, slightly more than 26 per cent. It is also interesting to note in the same table that from 1922 to 1932, inclusive, the 'wells abandoned after producing operations' numbered 217, whereas during 1933, 1934 and 1935, only one such well was abandoned. It is not within the scope of this statistical bulletin to give a detailed history of acidizing operations in the Toole County fields or to discuss the possibilities connected with the more general use of acid in the future. If any reader should desire any further information on the subject, it is suggested that inquiries be addressed to the concerns engaged in the business of acidizing wells, to-wit:

"Dowell, Incorporated, Shelby, Montana.

"Big West Acid Company, Kevin, Montana.

"Oil Well Acid Treating Company, Kevin, Montana."

Incidentally, the Big West Acid Company and the Oil Well Acid Treating Company later became licensees of the Dow Chemical Company, and since 1937 or 1938 the Big West Company has left the field, but the Oil Well Acid Treating Company or its successor is still a licensee of the Dow Chemical Company.

The Court: Of all those that were named in there that they might write to to get the information, how many of them were already under license from the Dow? A. At the time of this article only Dowell, Incorporated.

The Court: None of those others had been licensed? A. Not at that time.

The Court: How soon after were they? A. The Big West Acid Company became a licensee in 1937, I believe, and the Oil Well Acid Treating Company, or its successor, became a licensee in I believe 1938.

The Court: Did you have anything to do with their becoming licensees? A. No, sir. I left the Shelby area in December, 1935, and this article was published November 15, 1936.

Witness: May I read the last paper?

Q. (By Mr. Conner): And you had nothing to do with the writing or publishing of this article? A. No, I never saw this publication until you handed it to me a few days ago.

Mr. Owen: Ever hear of it before? A. I did not.

The Witness (reading): "The Oil Conservation Board regards the acid treatment of oil and gas bearing formations as the most important and valuable contribution yet made to the expansion and conservation of our oil and gas resources and its development and use under proper regulation and control is destined to be of incalculable benefit to the State of Montana and its citizens."

Mr. Conner: I offer this Bulletin S-1 as PX-196. which exhibit shall include the certificate appended to it. R. P. Jackson, Secretary of the Oil Conservation Board of the State of Montana, identifying this publication, stating the same is a certified copy.

The Court: Now, I think your objections are all right, but I will give you a chance. PX-195 is this Journal. Any objection to that?

Mr. Lyon: Yes, we make the same objection we make to all exhibits to PX-192.

The Court: That applies to both of these exhibits, 195 and 196, which I admit, and you have your objection.

Mr. Lyon: I have no cross-examination of this witness.

ORLIN W. LYONS,

a witness called by plaintiff, testified as follows:

I studied mechanical engineering at Oklahoma Agricultural and Mechanical College for four years, and have been employed by Dowell Incorporated since August 7, 1936, first as a treating engineer engaged in acidizing oil and gas wells and then as a station manager engaged in the same work and supervising the work of others.

From July, 1937, until September, 1938, I was station manager for Dowell, Incorporated, at Borger, Texas, where my duties were to acidize and supervise the acidizing of oil and gas wells in that area for Dowell. Commencing about July, 1937, I made a study of the effects of acidizing on gas wells that were acidized by Dowell in the Borger, Texas, area. Prior to this a few gas wells had been acidized, but they were more or less unsuccessful. Dowell checked the results of the treatments it made. This was done by ascertaining from the well owner or operator the gas production of the well before and after acid treating it.

The results of this study were made public in an article I prepared entitled "Gas Well Acidizing" appearing in the September 12, 1938, issue of the "Oil Weekly."

Mr. Conner: A copy of the article is offered as PX-327.

On page 38 of the article appears Table 1 entitled "Increase in Flow Obtained by Acidizing Texas Panhandle Gas Wells." This table lists gas wells designated by the numerals 1 to 47, and for each well shows the number of gallons of inhibited hydrochloric acid used in treating the well, the number of stages used in the treatment (the production of gas from the well before acidizing, the production of gas after acid treating it, the percentage increase and the increase in cubic feet of gas from each well per gallon of acid used to treat it. For instance, example No. 1, 3,000 gallons were put in at stage 1, the production before acid was 3,000,000 cubic feet per day and after acid was 6,800,000.

Table I of the article refers to these wells only by numbers 1 to 47, and gives no data which identifies the owner of the well. I now produce three typewritten sheets marked "Table 1" and "Table 2." The information on these sheets appears to be the same as that contained in Table 1 of the article in the Oil Weekly, except that the typewritten sheets give Dowell's treatment number, the company name, the well name and the treatment date.

Mr. Conner: The three typewritten sheets are offered as PX-328.

This information and data as to production before and after acidizing and the identity of the well was furnished by the well owner, while the data concerning the date of treatment and quantity of acid used came from the records of Dowell, Incorporated. The data under "Treat. Number" are Dowell's Serial Numbers. The wells are listed in the order of their size, for purposes of comparison, which accounts for these numbers being mixed up. The last two columns are calculated values. The figures under "Before Acid" and "After Acid" refer to cubic feet of gas.

The well showing the greatest percentage increase on this report is Treatment No. 511 for Phillips Petroleum Company, being from 4,690,000 to 38,698,000, or 725%; the one showing the next highest increase is No. 401 for Shamrock Oil & Gas Co., being from 12,000,000 to 81,000,000, or 575%, and the third highest is No. 463 for Panhandle Eastern Pipe Line Co., being from 5,400,000 to 34,400,000, or 537%.

During the period from July, 1937, to September, 1938, Dowell, Inc., treated approximately 80 gas wells, about 40% of which were treated by me personally and the rest were treated under my supervision. During the period for which data was collected there were 67 treatments, so that there were twenty treatments not referred to in the article in the Oil Weekly.

As to why I didn't include those other wells in this article, I figured that that was a representative group of wells that would show the type of work that we were doing at that time, and I left out several of them because they

were not representative wells, there were particular conditions attached that didn't make them a representative treatment. For example, in the Texas Panhandle you have a very complex formation. You have productive zones out there that are sometimes 600 feet, and in those productive zones will be scattered shale, dolomite, lime, arkosic material, and granite wash, and those wells are drilled with cable tools, and it is rather hard to collect the samples of the formation from a gas well because after you once start drilling why the cuttings blow out as fast as you drill, and they are blown out of the hole at such high velocity it is rather hard to catch your samples. And, for that reason, sometimes the drilling logs of these wells were rather incomplete, and there have been instances where all we had to go on was the company records, and some of these wells might not show any granite wash. Granite wash is granite pebbles carried down from the granite ridge in this particular formation, and it is non-acid-soluble, and it is permeable, and if your acid goes back in there there is no reaction, and you couldn't expect to get an increase in acidizing if you put your acid away in the granite wash.

The Court: What makes you put it in there, if you know that? A. If you don't know it is there, if the operator tells you here I have got a lime well, I would like to have it treated; the pay is from such and such a depth to such and such a depth. Why, you have no records of that.

The Court: Can't you believe those men, what they tell you? A. Well, you have to.

The Court: But that is what you believe for your statistics, if it is on top, and what they did get afterwards, these same men that are so untruthful? A. They are not untruthful, Your Honor. It is just the fact that they can't catch these samples, and they don't know the condition.

The Court: How do you know afterwards, then? A. Well, afterwards, if you put acid into a well, into a gas well, and it is a limestone formation, you don't get live acid back out. It is reacted acid. But in several of these treatments we found we had put acid into a non-reacting or non-

soluble formation, because we got live acid back out of them. Then we were into either the granite wash or the arkosic zone.

The Court: You mean there wasn't any lime in there at all them? A. Well, yes. The upper section would be lime, and the bottom section where the acid would—the granite wash is more permeable than the dolomite above, and your acid is going to go where there is the least resistance to flow.

By Mr. Conner:

Q. I show you a tabulation on gas wells, and ask you to state whether or not that appears to be a complete list of some 67 gas wells, of which you made a survey, to show the effects of acidizing those wells, and state whether or not that list includes the 47 wells that you reported in your printed article in the Oil Weekly (handing document to the witness)? A. It appears to be that.

Mr. Conner: I ask that this be marked PX-329.

The Court (indicating): Now, begin at the beginning, begin at the top and go down, and I want to put a mark on the original, of those that are not in your advertising, so that I can look at them. I am marking them right on the original so if anybody else is ever interested they can look; 402 is left out. A. 407 and 399-A are all one treatment and are left out, 405 is out; also 468, 469, and 492, and all the rest, 493, 96, 97, and all down to the bottom of the page are left out.

The Court: Well, now, these numbers—now, what do these treatment numbers mean, are they the order of treatment, or what? A. That is the order. Now, you see that they are not in—they are not in line there because we treat oil wells also; these are just gas well treatments. Treatment 503 to 506 might mean we treated 504 and 505 for oil well treatment.

The Court: But these are in the order of time, this arrangement, are they the treatment numbers? A. That is correct, I am pretty sure it is. Referring to PX-328, which is the table 1 comprising the wells that I reported in my

written article, the highest percentage of increases was 725 and the lowest percentage of increase was 29 per cent.

Referring to PX-329, the percentage increase of each of the wells that I left out was as follows: No. 374, the percentage increase was 73.

The Court: What is that figure from? A. That is taken from this sheet here showing the percentage increase of the wells that are left off of this sheet.

The Court: You did include there a 69 though and a 33, in those that you did publish? A. That is right.

The Court: And you left off a 73, which is higher than two that you have left off that I see? A. I would like to point out that these treatments are made in stages and due to the type of formation we are dealing with we had to more or less feel our way along in these treatments, and we put in one the gallons of acid to clean off the face of the pay, and then we would blow that acid out, take the dirt and the shale partings, and general impurities out of the well, and then introduce some fresh acid down and inject that out into the formation, and as a general rule the washing operation, which was the first stage, didn't show a particular increase in production, all that did was prepare the well for the subsequent acidizing stages, and so in order to tell whether we were going to do any good or not we had to put two stages of acid in there, and if the well looked as though it wasn't going to respond, we left the last stage out, we didn't go ahead and complete the treatment, and that is one of the reasons why I left out these ones here that you see are zero per cent and you will notice there are 4000 gallons—

The Court: Now, weren't all the things that you left out honest hazards of your business? You were honest in all you did, made an honest effort with all of them? A. That is right.

The Court: And these were hazards that went wrong? A. That is right.

The Court: But you left them out when you went to the advertising, and they are legitimate hazards of the busi-

ness, they are things if you were going to do the thing over again you would run into those same troubles, wouldn't you? A. Yes.

The Court: And the man, if that treatment doesn't turn out good and they don't get rich out of it, that is a legitimate, honest answer, and, in order to show the whole picture, you need the whole sheet there, don't you? In order to just show what you actually accomplish and it is fine, it is good, but isn't that true, now, that in order to show just how much good you do and how much you don't do, you need the whole record in that part of it? A. Well, we could tell now a little more about how to do that, and we could avoid such wells as that, because the public out there is educated to what is necessary for proper acidizing, and they can keep their wells in such a manner that we have a little more data on the well before we start acidizing.

By Mr. Conner:

Q. Will you please continue and point out to his Honor the ones, starting with the wells that you left out, by treatment number, and refer to the percentage increase, if any? A. Well, there is treatment No. 402, is zero per cent increase. 407 is zero per cent increase. 405 is zero per cent increase.

The Court: Did you get any decreases at all? A. None here, your Honor.

There are 7 wells on this tabulation that show zero per cent increase, down about the middle of the second page. Commencing with the treatment No. 493, on the second page, and from there down to treatment 535, I did not include any of those wells in my printed article.

Q. Will you just run your eye over the column which says percentage increase, and read off the percentage increase of those wells that you did not include in your published article beginning with treatment 493? A. 315 per cent. 92 per cent. 126 per cent. 45 per cent. 89 per cent. 55 per cent. 63 per cent. 726 per cent. 401 per cent. 608 per cent. 957 per cent. 8 per cent. 140 per cent. 35 per cent. These were not included in my written article.

The Court: When was that article written? A. It was written in—the rough draft was prepared in the latter part of July, or August.

Q. When were these wells treated? A. The last date I see is June 30.

Q. Were the figures on these wells available to go in the article if you had so desired, or had elected to put them in? A. They were.

Q. How does it happen that the last fifteen were left off? It looks to me as if you started to write that article, but you did not take a single one of those later ones. Have you got some explanation as to why you left out that period of time? A. The only reason I can give is that when I was preparing this, I had the list in front of me, and I took them down until I thought I had enough examples, and just took them in order, and left out the ones that I did not consider representative.

The Court: Are you sure that you had this list? I see that every one of them is left off here, which leads me to incline to think that you did not have those figures. A. I had the figures available at the time. I don't have my original data sheet here.

The Court: You have not put down in your published article a single one that you did not get an increase? A. That is right.

The Court: You have left them all out. It is not a fair showing, to make statistics in that way, and that is the reason why I do not accept it, in that way. I accept this complete one here, but that other one doesn't mean anything to me at all. I have got all I want on this one sheet (PX-329).

Mr. Conner: We are producing a complete sheet here, and I believe I asked the witness why he did not have this data before him, the list of wells. at the time he wrote the article, and he tells me, and he tells you that he did. That is all I know.

The Court: I think he is mistaken. I think he is absolutely honest, but I think he is mistaken about that. There

is nothing that people get more mistaken about than on dates. A. I don't think I am, your Honor.

The Court: You were getting out this history up above, and then you come down here, and there are some good ones down at the bottom there, and if you had had them right before you, I am of the opinion that they would have gone in, and I think you are absolutely honest with me, but the extent to which people, when they are interested in a thing, are influenced by that, is something amazing.

By Mr. Conner:

Q. Mr. Lyons, I ask you if you have made any particular study or survey, either by actual work in the field or by study of Dowell Company records, which would reflect the time that acid is in contact with the tubing during an acid treatment of wells, and, if so, state how you made that survey, and when you made it, and where you got the information? A. Well, of course, my duties have been, in the past, to check treatment work in the office in Tulsa for treating techniques, and, of course, I did not compile any data at that time on the length of time it would take to introduce acid. The average length of time it would take to introduce acid in the well. But since this trial has started, I have had 122 treatment records sent up here on 97 consecutive Arbuckle dolomite wells in Kansas, and I have computed the—observed the length of time the acid was in contact with the tubing down those wells during those treatments.

Q. I hand you three sheets of paper and ask you if you can identify that as data taken from those 122 consecutive treatments? A. Yes.

Mr. Conner: I ask the reporter to mark these sheets as PX-330.

Q. I likewise hand you a sheet of paper and ask you if those are your calculations based on PX-330? A. They are.

Mr. Conner: I ask the reporter to mark that sheet as PX-331.

The Witness: I have in my possession the treatment

records from which PX-330 was compiled and have computed each of those treatment records for the 122 treatments in order to identify the treatment number, the owner of the well, the well name and number and also to find from the treatment records the time that the acid was in the tubing in hours. Where the well was treated a second time I have identified that treatment record by treatment number and shown how long the acid was additionally in the tubing by hours. In the last column of PX-330 I show the total time in hours that the acid was in the tubing for each of these wells. I compiled this from our company records.

The Court: These figures are kept in the ordinary course of your business? A. They are recorded on each and every official treatment.

The Court: And there are many purposes for keeping these other than advertising purposes in your business? A. Yes, sir.

The Court: I will admit it as part of—when I find a system of records and bookkeeping that is good enough for people to rely on in their own business, I admit them.

Mr. Lyon: If the plaintiff wants to take all the time it wants in acidizing a well with its inhibitors, that has nothing to do with what the defendant does. We have the records here of what the defendant does, and they have already been referred to. What the plaintiff does has nothing to do with this case.

The Witness: PX-331 gives the average gallonage used in treating 97 consecutive Arbuckle dolomite wells, comprising a total of 122 treatments. The average gallons of acid is 1089½ gallons. Average of maximum treating pressure is 528 pounds per square inch. The average time acid was in the tubing is 7 hours 1 minute. The average internal diameter of tubing shown in this treatment is 2.66. The average length of tubing shown in that treatment is 3211 feet, and on this sheet is computed the square feet of surface area in 3211 feet, which equals 2241 square feet, equals the average internal surface of the tubing in these treatments.

By Mr. Conner:

Q. Mr. Lyons, have you had any occasion to learn what the hauling charges are in the oil fields, that is, trucking charges, and, if so, tell the court how you came to learn that and what those charges are? A. During the time when I was station manager in Pampa and Borger, Texas, why, we had occasion to hire trucks to haul extra gallonage of acid out to wells, and then at several times later on, since that period, I have had occasion to hire trucks to haul special equipment out to wells in conformity with my duties in that capacity. For a medium sized truck, the average price is around $5 an hour. For the big, extremely heavy-duty trucks, it runs in the neighborhood of $7.50 an hour. In my work of treating wells with acid I have had occasion to learn what the costs or charges are of pulling tubing out of a well, and the charge or cost of running the tubing back into the well. Several times in the past, in working up new treating techniques, we have had to pull tubing and lower special tools into the well, and often in going over this type of treatment with the operator, why, the cost of doing this work was weighed against what we might expect in results from the treatment, and the average figure that I remember—of course, it can vary all over the map, but the average figure would be around $85 a day for a pulling unit and crew to run tubing. The figure will vary because of different depths of well, the different types of pulling machine, or whether the well has a rig front, or whether the rotary rig is still over the well. If you have to tie up a rotary rig to do this operation it would cost you much more. Taking that figure of $85 for machine time and crew time, you could run and re-run tubing in a 3000 foot well in about a day, and that would be $85.

Q. Have you read the Frasch patent recently? A. I have.

Q. You noticed therein that they proposed to use a specially prepared tubing for treating their wells under their method? A. Yes. They refer to either enamel-lined, enamel coat, or rubber-lined and rubber-coated tubing, or lead-lined, lead-coated tubing.

Q. And, in order to use such a special tubing, you would have to run it into the well and then pull it out of the well again? A. That is right.

Q. Before you could do that, you would have to also pull your normal tubing, and after you had used your special tubing, run the normal tubing back; is that correct? A. That is correct.

Q. So you assume that you would have at least two complete pulling jobs, that is, running and pulling?

The Court: Have you made any figures or estimates on the average value of the increase in oil, as to how much you increased the well? That is, the relation that that bears to the expense, of course, is just as important as the expense item? How much did you increase the value of each well, on an average? A. The percentage increase?

The Court: No. In dollars, the increase in dollars, if you have any idea at all? A. Well, that is kind of a hard question to answer.

The Court: I know it is. You don't know how long they are going to run, of course? A. One well may make only a gallon of oil, and it is temporarily closed by treating, and you acidize out the corner area, and you open the natural flow up, and you get a fairly big well, there you have got an awful big increase.

The Court: $85 does not mean much in the inducement proposition, or the discouragement proposition, unless I know what the stake is, do you see? In some places, and under certain conditions $85 is an awful lot of money, but in other places it is just a bagatelle.

Mr. Conner: But there would be two pulling jobs as a minimum, each of which would cost $85.

Mr. Lyon: If your Honor please, the point I am objecting to in connection with those figures is that they have nothing to do with the defendant, or nothing to do with anything that has happened in your district here in Michigan that the defendant has done. These are something the witness has taken from records in September, 1936.

The Court: But they throw some light on the industry

we are dealing with. I agree it doesn't show what you have done. And the very fact it occurs before this suit started, and I am satisfied it wasn't being done for the purpose of a lawsuit, it is a record of what you do in your own business there. Just what do you claim when you show how long they had it in? Your purpose is to show that it would eat a lot of iron and use up a lot of acid?

Mr. Conner: If it is raw uninhibited acid.

The Court: Yes, that it would use up a lot of acid and also eat up iron, you show it for two purposes.

CROSS EXAMINATION

By Mr. Lyon:

Q. Let us go back to this first table that you produced, or, this first exhibit that you produced. your published article, that is PX-327. During the time that you were acidizing those gas wells out in the Panhandle, the Chemical Process Company was doing the same kind of work, were they not? A. Not during the first part of the period, to my knowledge. I think that you will find that May, 1937, was the first of the treatments included in PX-328.

It is hard for me to fix the date when the Chemical Process Company started in that field, doing that same work, but it was roughly after the first of the year in—shortly after the first of the year in 1938. However, they were in the Hugoton area in Kansas in the latter part of 1937. I am not sure that the Chemical Process Company was not there in the Panhandle acidizing those gas wells as early as September, 1937, because they may have acidized a well or two from their Hugoton station, coming across the Oklahoma Panhandle down into the Texas Panhandle at that time.

My article, PX-327, was published in September, 1938, in the Oil & Gas Journal. In the earlier issue of the same publication, of May 19th, 1938, Mr. M. E. Chapman, of the Chemical Process Company, published an article on the

same subject entitled "Acid Treating of Gas Wells to Increase Production." It covers the same general line, acidizing gas wells, as was covered in my later article. The table in the Chapman article "Partial List of Gas Wells Treated in Hugoton Area, Kansas" refers to gas wells, but not using the same methods. We used a gas load method of treatment, where they used a water load method of treatment. That means after you get the acid into the tubing then to pump it, force it down, follow it down, we use gas and they use water. We have gas compressors, portable gas compressors to build up enough gas pressure, rather, on top of the acid, to overcome the resistance to flow in the formation.

By Mr. Lyon:

Q. Did the Chemical Process Company in the Panhandle obtain comparable results to those you reported that was obtained by your company on these gas wells? A. Now, during that same period I don't recall any production figures on Chemical Process' production data.

The Court: You had seen their publication probably before you got yours out there? A. That is the first time I have seen that, that I recall, your Honor. This publication says it was presented before a meeting of the American Gas Association at New Orleans on May 9th to 12th, 1938. I was not present at that meeting. I might have seen this publication before, but I don't recall it.

The Court: I take it the competition has been pretty keen between all you people; there haven't been many of you, and it looks as though you had a battle between you; hasn't there been real competition, real keen competition? A. We certainly had competition.

The Court: I imagine you are each reading all the other says, and all the advertising? A. Well, not from my own experience.

By Mr. Lyon:

Q. Well, you know, don't you, that you have had substantial, real keen competition from the Chemical Process Company in the fields that you have been working in ever

since you have been working for Dowell? A. That is right, there has been competition.

Q. Now, in this article, Mr. Chapman of the Chemical Process Company says this, after describing his method which you have already explained:

"By using this method a well was treated in the Panhandle of Texas in 23 minutes using 5,000 gallons of acid followed with a water load of 53 barrels. The well was allowed to be shut in 20 minutes awaiting chemical reaction. Before treatment the well had a rated potential of 16,900,000 cubic feet of gas per day. After treating, the well gauged 65,000,000 cubic feet. Samples of the spent acid solution following the treatment indicated that the acid was completely neutralized."

Mr. Owen: Now, if Your Honor please, I object to the reading of the paper into the record as evidence. If it is for the purpose of cross-examining the witness, all right, but it doesn't prove the facts stated in the document.

The Court: I think that is right. It is more advertising by a third party.

By Mr. Lyon:

Q. Now, isn't that description of the results obtained there consistent with the results that you know were obtained by the Chemical Process Company in that field, in acidizing those wells? A. Well, I can answer it this way, in that I haven't personally gone around to companies that Chemical Process treated for and asked them what their production results were. All that I would know would be hearsay.

I did not check up any of our competitors' results out there in the same manner that I checked up our own. During the time that I was out there, our competition treated very few wells, and I didn't check, actually check up on the production. I don't actually know whether they performed such an operation as they say and obtained such results as they say. I don't know anything about how long it took them to acidize the gas wells out there. As a matter of fact, I don't think I have ever seen Chemical Process

treat a well other than if I happened to be treating a well on one location and they were on another, I might observe them tied into a well, but I have never gone and watched them treat a well.

Mr. Lyon: I would like to offer this advertisement—this article—if it is an advertisement, I suppose all these articles are written for the purpose of stimulating business, your Honor—I would like to offer this article of the Chemical Process Company, which I have identified, which was published in the Oil & Gas Journal of May 19th, 1938. The witness' Exhibit 327 was published the following September. I offer this to show that similar advertisements, similar articles had been published by others before the witness' article was published.

Mr. Owen: I object to the exhibit.

The Court: If they support theirs by testimony, and if they brought the data sheets in, why—

Mr. Lyon: I am not offering this to prove the facts stated. But I am offering to prove that such an advertisement was run by a competitor—that such an article was written and published in the same magazine before their article was.

Mr. Owen: I object to that as irrelevant and immaterial, your Honor.

The Court: I will let you mark it and put it in. I do not know what use I can make of it. We will call it DX-332.

(The document in question was thereupon marked Defendant's Exhibit No. 332.)

The Witness: The Hugoton field that that article talks about is entirely separate from the Texas Panhandle gas field. It is approximately 90 miles distant. It is a slightly different producing formation, different structure. The Hugoton field is, if I remember correctly, slightly deeper.

In these treatments which are set forth on Exhibit 329, we employed in acidizing those wells, either AD or A, I don't know which. I don't know what the material was that constituted the inhibitor.

Referring to those wells in Kansas in September, 1936, which are listed on Exhibit 331, I was not there when those jobs were done. All I know about that is what I found in the records, except that I happened to be in Kansas during September of 1936, and I knew that we were having this type of work done. I was not personally present on those particular jobs that are included on this list. I don't know of my own knowledge about these times. I took them off some records in Tulsa. I have not had custody of those records since 1936; that hasn't been my job, to keep those records. All I know about what inhibitor was used in those 97 jobs that are referred to on Exhibit PX-331 is what I told you before.

The Court: What are these numbers that are omitted from PX-331? You started in and I find 1802, 3, 4, 5, and 1806 are missing. A. That would be either some other type of formation or some other type of treatment, that is other than Arbuckle dolomite. We are trying to compare this on one particular formation so that the wells would be more or less uniform.

By Mr. Lyon:

Q. You go down to No. 1831, and then the next number is 1848; there were 15 jobs between those numbers; what were those jobs? A. I don't know.

The Court: There are individual ones omitted. 1821 isn't there. A. Oh, yes, lots of them.

The Court: 23. All the way along they are omitted.

By Mr. Lyon:

Q. What do you mean that these are consecutive? A. They are consecutive Arbuckle dolomite wells. There are all kinds of producing formations in Kansas, and we just picked one particular producing section so it would be more comparable.

The Court: When did you select those? A. Since this trial started last July.

The Court: If you used other kinds, what kind of showing would you make? A. I have no idea, your Honor. I asked the office in Tulsa to send me approximately 100 con-

secutive dolomite treatments during this period. I could not answer that question.

I do not know that these omitted ones are not dolomite treatments. I requested this and this is what they sent me. I asked them for approximately 100 consecutive dolomite treatments. The Arbuckle dolomite is noted for its low initial permeability. I do not think that these treatments on that dolomite show an extreme example of taking a long time to get the acid to penetrate the formation and leave the tubing. I think it is a good representative showing of tight wells that we encounter in treating in several areas. As to whether this is unusual, this is as high as any. I can't answer definitely. It is high, yes. It is high. But you will notice here that the range goes from fifteen minutes—I believe I am correct in that—

The Court: Have you got a copy of your letter in which you asked for what you wanted? A. I telephoned.

The Court: Did you tell him what you were trying to prove and what the other side was claiming, so he would kind of know what he was looking for? A. In this conversation I told him I wanted approximately 100 consecutive dolomite wells, and I explained to him that I wanted the records themselves so that I could compute the treating time.

By Mr. Lyon:

Q. Didn't you want him—didn't you tell him you wanted to get a selection that would give you an average time of about seven hours? A. No, I did not.

Q. Well, these columns that are headed time, total time in hours that the acid was in tubing, or total acid—total time acid was in tubing in hours, that doesn't mean that the total amount of acid was in the tubing that length of time, does it? A. In order to figure that, you have to have some index point. And that is where—the index was taken as the bottom of the tubing, and the time was figured from the time that the acid was lowered to the bottom and until it was flushed out of the tubing. That means that that one particular portion of the tubing was in contact with the

acid for that period of time. As to whether that means that all of this acid that was used in that operation was acting on that point of the tubing for that full length of time, it means that that point was in contact with the acid for that period of time. I do not know how to explain it in any other way. Your acid is moving down the tubing, and that point was in contact with the tubing. 1089 gallons of acid was employed in these jobs, on the average, and the average tubing depth was 3211 feet. As to how much acid that tubing will hold it all depends on the size of the tubing. I can give you the figures for this, that is, the 3-inch tubing holds 8 barrels per thousand feet; the 2½ inch tubing holds 5.7 barrels per thousand feet; the 2 inch tubing holds 4.8 barrels per thousand feet. There are 42 gallons in a barrel, and in that depth for 2½ inch tubing, it would be about 19 barrels, and that figures out about 1550 gallons. You could put 1500 gallons in a 2½ inch tubing that deep.

I have no idea what these times would be if I had these other omitted treatments here, had those included in the average. It might be higher, or it might be lower. As to what those other wells were that were omitted, all I know is that we were treating the formation known as the Chat, and we were treating the Viola, the Simpson, and the Mississippi Lime, and several other formations. We then used practically the same type of pump that we now employ.

By Mr. Lyon:

Q. I notice Mr. Chapman says in his write-up, Defendant's Exhibit 332:

Reading: "Although the pumps used in acid work are extremely efficient with regard to high volume and high pressure, operators generally favor the multi-pump hookup. On large acid shots, two or more pumps are used to inject the acidulated fluid into the wells. Recently a well was treated in Young County, Tex., with 20,000 gallons of acid. This acid charge was followed with an oil load of 230 bbls. Ten pumps were connected and delivered fluid simultaneously. The overall treating time on this well for the acid and oil load was 59 minutes." Now, have you done the

same thing in your work? A. I have never hooked 10 pumps up. The most I have ever used was three pumps.

Q. Well, what would be the average time that the acid would be in the well—I mean in the pipe in these 97 jobs reported on PX-330, if you omitted the ten per cent of the jobs which were the highest jobs? A. Well, there are some figures here on the back; 18 treatments were 12 hours or over, or 14.75 per cent of the total; 35 treatments were 6 hours or over, or 26.68 of the total.

Q. Well, that doesn't add up to anything; I say suppose you just take—how many of these treatments are above 25 hours, let's go through; you have said the average is 7, let's go through, there is one at 53, No. 1, one at 33, that will be 2, one at 29 would be 3, one at 55 would be 4, one at 36 would be 5, and one at 43 would be 6, one at 27 would be 8, another 27 would be 9, one at 29 would be 10, one at 31 would be 11, one at 46 would be 12, one at 31 would be 13, one at 33 would be 14. Now, I suspect if you take those 14 out of that that you have averaged in with those 97, your average time in this thing, instead of being 7 hours would be under an hour. Just look at that and see if you don't think so? A. Well, it is obvious that it would reduce it, but I don't know—

Q. Most of these figures run around, some of them half an hour and some of them one hour and one hour, one hour?

The Court: One fifteen minutes.

By Mr. Lyon:

Q. Yes. Now, if you would take these fifteen out of here, or fourteen out, what kind of a time are you going to get? A. Well, I would have to total it up and divide it out in order to answer that question correctly. Offhand, it looks like you would reduce down to in the neighborhood of 3 hours.

Q. Well, we can all do that, I suppose. Now, you don't know whether the actual times of treatment for these wells, intermediate wells, or intermediate treatments, that are not reported on this sheet, are longer or shorter than those that are reported? A. No, I don't know.

These omitted wells in this series which is reported on PX-330 were in different formations, assuming they carried out my request. I asked for Arbuckle dolomite wells, for the reason I gave you a moment ago, it is noted to be of extremely low permeability initially. As to what formations were treated in the treatments that are omitted in the series that is noted on this Exhibit PX-330, I stated that a moment ago, that they would possibly include the Simpson and the Viola and Chat and Mississippi limestone. The Chat formation will treat a little bit easier than the dolomite. It is a little more highly reactive, and while the well may be tight to start with it shows a fairly rapid decrease in resistance to flow after the treatment progresses. The Simpson will vary depending on the locality. It may be the Simpson formation will be harder to treat than a dolomite, but it is highly variable. The Mississippi limestone is another highly variable. Some of those wells are extremely low initial permeability, and don't increase in permeability very rapidly as you progress with the treatment. The Viola is in the same class as the Chat, namely, that it increases.

By Mr. Lyon:

Q. You have referred to the cost of a tubing job as maybe being about $85. That would be high for many tubing jobs and low for others, wouldn't it? A. That is right.

Regarding the price that the operator has to pay for an ordinary acidizing job, the minimum price for a 500-gallon job is $175. I believe that that was the price in 1936. For a 1,000-gallon job the price is $250. That includes the base service price, and then after you use higher gallonage, the price goes down proportionately. After you have used 1,000 gallons, the next 1,000 does not cost as much. For a 2,000-gallon job it is $250 for the base service charge, for 1,000 gallons, and then 18 cents a gallon thereafter for the additional acid up to 5,000 gallons. An approximate figure for the average amount of acid on the jobs that are performed by our company, I would say would be between 3,000 and 4,000 gallons. A typical job

of acidizing that is done by our company is not on an old well, that is producing maybe one or two barrels of oil a day, for the purpose of increasing it to three or four barrels a day. The trend has been in recent years to acidize new wells on completion. However, we still acidize quite a few old wells.

Q. It would be safe to say that you would not be in business, you couldn't afford to operate if what you were trying to do and the only business you had was trying to increase old wells that were down to one or two barrels a day, or three or four, up to maybe three or four times that? If that were the only possibility in the wells you would not be in business, would you? A. The answer is obvious that you wouldn't. It is a matter of economics there, and you have to qualify that by assuming the price of the oil is low.

Q. In other words, people couldn't afford to spend $300 or $400 for an acidizing job on the kind of wells that I mentioned? A. Well, it is purely a matter of economics, and if you can get a five-barrel increase in production that will stay up and maintain a five-barrel increase in production for a long period of time, then it is possible that that might pay a rather high rate of return on a relatively low investment. In other words, there is lots of people will invest $200 to get $5.00 a day back for a considerable length of time.

Q. Well, you couldn't depend on that kind of wells to run your business, could you? That is obvious? A. Well, I think the answer is "no" to that.

I do not intend by my testimony here about the cost of pulling a string of tubing, that the judge should understand from my testimony that an acidizing job is prohibitive if it is necessary to pull a string of tubing in connection with the acidizing job. Our acidizing jobs sometimes involve pulling a string of tubing, depending upon the type of treatment. Our acidizing treatments where we use an acid jet gun require the pulling or the reinsertion of a string of tubing. An acid jet gun is a tool that we have

developed to impinge acid at high velocities against the formation, and take advantage of the erosion effect which you get from impinging the acid at high velocities in conjunction with the chemical effect that you get. The acid jet gun consists of a metal tube that has jets placed in it, 1/16th of an inch jets placed in it, 120 degrees apart, and around the barrel, one foot apart, up and down the barrel.

In using the type of tool I described it is necessary to make a special tubing run to get the tool in and to remove the tool it is necessary to pull the tubing out, but to eliminate that procedure we have developed a jet gun that we run inside the tubing and eliminate that. We did use the tool making special tubing runs commercially and charged for it and did quite a business with it, but it proved to be awkward and so we developed this other one.

As to what other types of acidizing operations where you have to pull or run a string of tubing, if you are going to use a packer to confine your acid to a certain section, if the packer wasn't a part of the well before hand, you would have to pull the tubing and put a packer on. Relatively few of the treatments are made that way. It is not an uncommon thing to do in the business of our company. It is done a good many times over the course of a year.

Q. And in all those cases you have to run a special string of tubing and remove the tubing at the end of the acidizing operation? A. It is not a special operation—it is just the tubing with a packer on it.

That is all the situations, types of acidizing jobs, done by our company in which we have to make a special tubing run that I can think of right now, other than the kind where the operator wants to clean out his well before acidizing, but we do not have anything to do with that.

Q. Well, isn't it perfectly obvious to you that if there was no other way of doing it, that acidizing would still be worthwhile, or worth enough to your customers to warrant their making a special tubing run? A. Why, in the developed state that it is now, I would say "Yes."

Q. Isn't it true that in oil field operations the common practice is, for one reason or another, to pull the tubing in the well every few months, irrespective of any acidizing; I mean even if there is no acidizing involved? A. Well, that of course depends upon the field conditions or well conditions. In fields that have paraffin troubles, why, they will pull tubing; sometimes they have to pull the tubing to remove the paraffin. They certainly do pull tubing and replace it occasionally in wells when they do not pump right.

RE-DIRECT EXAMINATION

I stated that I took up my duties as station manager at Borger, Texas, and the Texas Panhandle, some time in July of 1937. I do not recall that Chemical Process Company had treated any gas wells with acid in the Texas Panhandle territory prior to my going there in July of 1937 as station manager. I knew that they were operating in the Hugoton area, which is removed eighty or ninety miles from there. Our first treatment in that field using this method, according to my tables, was May 10, 1937.

When you use the jet gun in acid treatments, you must pull the tubing and put on the gun, run it back in, pull the tubing and take the gun off. The gun is so constructed that you can produce fluid if you want to leave it in the well. You have got to make two round trips to recover the gun.

HEITHECKER STIPULATION

(Offered on behalf of plaintiff.)

It is stipulated by and between counsel for the respective parties that if R. E. Heithecker were called by plaintiff and sworn as a witness he would testify as follows:

I am a resident of Bartlesville, Oklahoma, and my address is care of the Bureau of Mines in that city. My education and experience include a Bachelor of Science degree in Mechanical Engineering from Purdue University, in June, 1924, employment in the production, refining, gasoline and purchasing departments of Empire Companies (now Cities Service Company), Bartlesville, Oklahoma, from July 1, 1924, to October 1, 1926, and employment by the United States Bureau of Mines continuously since October 2, 1926.

The Bureau of Mines was established by Organic Act of Congress (36 Stat. 369) approved May 16, 1910, effective July 1, 1910, and amended by an Act (37 Stat. 681) approved and effective February 25, 1913. An Act (40 Stat. 469) approved March 3, 1915, authorized the Secretary of the Interior to establish and maintain mining experiment and mine safety stations under the Bureau of Mines. In 1917 the Secretary of the Interior designated that one of the experiment stations should be devoted exclusively to petroleum and natural gas, and in 1918 the Petroleum Experiment Station was established in Bartlesville, Oklahoma.

My work with the Bureau of Mines has been in accordance with the provisions of the above acts and has included assignments as follows: In Laramie, Wyoming, from October 2, 1926, to July 1, 1927; in Bartlesville, Oklahoma, from July 1, 1927, to December 1, 1928; in Carlsbad, New Mexico, from December 1, 1928, to June 5, 1930; in Shreveport, Louisiana, from June 5, 1930, to March 15, 1933, and in Bartlesville, Oklahoma, from September 1, 1933, to the present. My work under said assignments has been on

problems relative to Petroleum and Natural Gas, and for a while on the drilling of potash wells in West Texas and New Mexico.

I am the author of Bureau of Mines Reports of Investigations No. 3251, published October, 1934, entitled "Engineering Studies and Results of Acid Treatment of Wells, Zwolle Oil Field, Sabine Parish, La.," and No. 3445, published April, 1939, entitled "Effect of Acid Treatment upon Ultimate Recovery of Oil from some Limestone Fields of Kansas."

As stated in the acknowledgments of these reports, the contained data were collected by me and under my supervision from the records of oil companies, acid treating companies and state oil commissions, including reports of production filed by oil producers in accordance with the requirements of Federal and State Statutes and Executive Orders. Before publication the reports were read, criticised and approved by engineers and officials of oil companies, acid treating companies and State Oil commissions as well as by the engineers of the Bureau of Mines, and the statements contained in both said reports are true and correct to the best of my knowledge and belief.

Mr. Conner: I offer in evidence as PX-69 the report of investigations by Mr. Heithecker which is No. 3445.

(The report of investigations No. 3445 referred to was thereupon marked as Plaintiff's Exhibit 69.)

Mr. Conner: Likewise I offer in evidence as PX-70 the report of investigations No. 3251 by Mr. Heithecker.

(The report of investigations No. 3251 was thereupon marked as Plaintiff's Exhibit 70.)

Mr. Lyon: We object to those, your Honor, on the ground they are hearsay and incompetent as proof of the statements of fact contained in the reports. They seem to be based on information obtained by Mr. Heithecker from other parties, and the other parties are not here to be cross-examined. They contain many matters of opinion, as well as purported statements of fact.

The Court: I think I should stick pretty closely to the

rule as to hearsay. All things of that kind ought to be considered with great care, in this court and all courts. So it doesn't come here in this court with any absolute presumption that they are right, I will tell you that.

The Court: I will admit these exhibits. I don't accept them as binding on this court as to what they say.

PX-69, Bureau of Mines Report on "Effect of Acid Treatment upon the Ultimate Recovery of Oil from Some Limestone Fields of Kansas," published in April, 1939, is in part as follows:

"INTRODUCTION

"In Kansas, almost every oil well drilled into a limestone formation is treated with hydrochloric (muriatic) acid upon completion. This is done to increase the potential capacity of the well and thereby increase its 'daily allowable' production (see p. 9), to shorten the time required to produce the recoverable oil, and to increase the quantity of oil recovered ultimately from the reservoir. The porosity and permeability of limestone formations seldom are uniform throughout the proved area, consequently the production capacities of completed wells vary considerably. Acid treatment of wells tends to increase production capacity and to equalize potential capacity." (Page 3.)

"If offset wells already have been treated with acid, new wells usually are treated to protect the property on which they are drilled against drainage. Even though competitive conditions do not exist in a field, it is generally assumed that the higher 'allowable' resulting from acid treatment will justify the additional cost of completing a well with acid." (Pages 3 and 4.)

"Acid treatment of wells also may be credited with extending the productive limits of some limestone fields in Kansas. Edge wells, which showed only small, non-commercial quantities of oil, have been completed as large oil wells after acid treatment, either alone or after being shot with nitroglycerin." (Page 4.)

"Acid treating marked an advance in the producing history of limestone fields of Kansas; in fact, many old limestone fields that almost had reached their economic producing limit were 'rejuvenated' and their capacity to produce increased several times. In the Fairport field (Russell and Ellis Counties), for example, production had declined to a daily average of about 10 barrels per well, and it was unprofitable to continue to produce many of the wells. After the wells had been treated with acid, the production per well averaged over 30 barrels per day for a year, even though the production was party curtailed through proration restrictions. The rejuvenation of the Arbuckle limestone wells of the Eldorado field, Butler County, is another example of the benefits derived from acid treatment. Many wells that had produced for 13 to 15 years and had about reached their economic limits were rejuvenated through the use of acid and continued to yield large quantities of oil." (Page 4.)

"Limestone structures that had been tested by drilling and found noncommercial were completed later as commercial oil-producing formations through the use of acid. The original development of the Kansas City limestone at Valley Center, Sedgwick County, yielded very few commercial wells, although enough oil showings were noted during drilling to deeper levels to indicate that oil was present. Evidently the low permeability of the Kansas City limestone prevented many of the wells from becoming commercial producers from this formation. After the deeper reservoir had been depleted of its economically recoverable oil, many wells were plugged back to the Kansas City formation and were made good producers by the use of acid." (Page 4.)

"Hydrochloric acid was used to treat oil wells in Kansas for the first time in October 1932. Treating programs were soon inaugurated by various oil companies; by the end of 1934, 944 wells had been treated and by the end of 1937, 5,824 wells. The total number of acid treatments given to wells in Kansas by the end of 1937 was 8,070, because many

wells had been treated more than once. These treatments consumed approximately 12,750,000 gallons of acid. The cost of the service to the operators is estimated at about $2,500,000." (Page 4.)

"ACKNOWLEDGMENTS

"The writer wishes to acknowledge the interest and assistance of the acid-treating service companies and of many oil companies for the generous use of their files on the acid treatment of wells in Kansas.

"Production statistics of individual wells, groups of wells, leases, and entire fields were compiled from oil-company records and from the reports of the Kansas State Corporation Commission. Well-completion records for the State were taken from the Oil and Gas Journal.

"This investigation was made under the general supervision of R. A. Cattell, chief engineer, Petroleum and Natural Gas Division; N. A. C. Smith, supervising engineer, Petroleum Experiment Station; and under the immediate supervision of W. B. Berwald, senior petroleum engineer, Bureau of Mines. C. F. McCarroll, C. R. Bopp, W. F. Krueger, and E. M. Tignor, of the Bureau of Mines, assisted in compiling the production statistics and treating records. The illustrations were traced by R. C. Wright and R. M. Himmelright.

"The writer is indebted to the following for constructive criticism of the report: L. C. Morgan, Morgan Acid, Inc.; B. M. Kingston and M. E. Chapman, The Chemical Process Co.; C. E. Clason, Halliburton Oil Well Cementing Co.; John G. Staudt and P. E. Fitzgerald, Dowell Incorporated; W. H. Burke and C. H. Keplinger, Shell Petroleum Corporation; A. W. Walker, Stanolind Oil and Gas Co.; E. O. Bennett, Continental Oil Co.; A. J. Lewis, Central Petroleum Co.; W. B. Lerch, Phillips Petroleum Co.; Sam Harlan and N. M. Hutchinson, Cities Service Co.; E. L. Rawlins, Union Producing Co.; E. G. Dahlgren and J. H. Page, State Corporation Commission of Kansas; Marvin

Lee, Petroleum Geologist, formerly with the State Corporation Commission of Kansas; and W. B. Berwald, H. C. Miller, N. A. C. Smith, C. C. Anderson, Charles B. Carpenter, H. D. Nichols, and C. F. McCarroll, all of the Bureau of Mines.

"The investigation was carried on in cooperation with the Kansas State Corporation Commission." (Pages 5 and 6.)

"SCOPE OF REPORT

"To ascertain the effects of hydrochloric acid upon the ultimate economic recovery of oil from limestone reservoirs, it was necessary to investigate the effects of acid upon the oil reservoirs from old, depleted, or almost depleted fields, individual leases, and groups of wells." (Page 6.)

"Studies were made of the production records and production-decline curves of the wells in the Fairport field, Kansas, and one 80-acre lease in that field was studied in detail. The records of three groups of wells in the Eldorado field were examined to estimate production trends before and after acid treatment. The wells were producing from different horizons, and from the estimates of production trends the net effects of the acid on oil recovery were calculated. The records of wells in the Kansas City formation at Valley Center also were studied. Many wells were plugged back from a deeper pay, and the upper horizon was treated to obtain commercial production. Production records of the Shutts field also were examined." (Page 6.)

"Acid-treating records from the various acid-service companies operating in Kansas and those from most of the oil companies that treated some of their own wells were tabulated and classified. It is believed that the records of more than 95 per cent of the oil wells treated in the State to the end of 1937 were available for tabulation." (Page 6.)

"ACID TREATMENT OF WELLS IN KANSAS

"Kansas oil wells were first acid-treated to increase production late in 1932, and the early treatments were very successful. Extensive acid-treating programs soon were initiated by many operators, both in old and in flush producing areas, and at present acid treatment of wells has become so general that few wells are completed in limestone formations without its use." (Page 10.)

According to the records of acid treatments, 5,824 wells in Kansas were given a total of 8,070 treatments to the end of 1937. In all, approximately 12¾ million gallons of acid were used. * * *" (Page 10.)

"FIELD STUDIES

"The use of acid has increased the production rate of many new wells that produce from limestone formations in Kansas, but it is seldom possible to forecast ultimate yields and to demonstrate that acid treating has increased them. For new wells, however, that would have been nonproducers if they had not been acid-treated, the entire recovery may be classed as increased yields. Other wells have been plugged back to formations that previously had been tested and found noncommercial and then treated with acid. Production from such well also may be classed as increased recovery." (Page 12.)

"Oil production for the (Fairport) field reached a minimum in May 1933 shortly after the initiation of acid treatment, when 36,456 barrels of oil were produced from 123 wells, an average of 10 barrels per well per day. In November 1933, just 6 months later, the field reached a new production peak of 140,490 barrels of oil from 125 wells, an average of 37 barrels of oil per well per day. Since then the output has declined, although additional wells were drilled and several wells that had been abandoned temporarily were put back into production. In June 1938, 145

wells produced 59,869 barrels, an average of 14 barrels per well per day." (Page 14.)

"ACID TREATMENT

"The first acid treatment of an oil well in the Fairport field was made in January 1933. Its success led to the treatment of other wells, and by the end of 1933, 95 wells had been treated. Second 'shots' of acid were given to only four wells during 1933, but during 1934 many wells received second and third treatments of acid. By the end of 1937, 260 acid treatments had been given to 175 wells, one well having been treated five times. A summary of acid treatments of wells in the Fairport field is tabulated in table 3 and shown graphically in figures 4 and 5." (Page 15.)

"STUDY OF ACID TREATMENT ON AN 80-ACRE LEASE IN THE FAIRPORT FIELD

"The beneficial results of acid treatment on wells that had been abandoned or that were about ready for abandonment is shown by the study of an 80-acre lease in the Fairport field. Because of its favorable position on the producing structure, this lease probably is one of the best of the field. Eight producing wells were completed on the lease between June 1924 and February 1926 with a pattern of 10 acres per well." (Page 15.)

"In 1932, the year previous to acid rejuvenation, the lease produced 12,622 barrels of oil, an average daily output per well of 4⅓ barrels. The daily average production of oil per well increased to over 7 barrels in 1933 and to 22 barrels in 1934, then declined to 12 barrels in 1935 and to 6½ barrels in 1936. It increased to slightly over 7 barrels per well in 1937. The quantity of oil produced in 1934 compared to that in 1932 represented an increase of over 400 per cent." (Page 15.)

"* * * At the time of production test before acid treatment, 1 well was temporarily shut in and the others showed a capacity of only 2 to 7 barrels of oil daily. After acid treatment the wells tested 30 to 108 barrels of oil a day. The first well treated on the lease tested 2 barrels of oil daily before treatment and 108 barrels after treatment on January 22, 1933. No other wells on the lease were treated until November 1933, so the increase in production of oil during most of 1933 probably was due to the increase from this well. Acid treatments in other wells on the lease in November 1933 and in the early months of 1934 increased the lease output to over 5,000 barrels of oil per month for about 1 year before a decline began. In November 1934 the lease produced 6,736 barrels of oil, a daily average per well of 28 barrels. During this period, the entire field output was curtailed through proration restriction. The 24-hour potential for the lease during the greater part of 1935 was 253 barrels but dropped to 83 barrels in December. In June 1936 it was raised to 107 barrels; later in the year it was lowered to 75 barrels, holding that figure until proration was lifted in August 1937." (Page 17.)

TABLE 4.—Acid Treatment Data on 80-Acre Lease[1/] in Fairport Field, Russell County, Kans.

[1/] Courtesy Central Petroleum Co., Tulsa, Okla.
[2/] No test, well had been shut in.
[3/] Increased to 90 barrels per day after 2 weeks.

(Page 18.)

"The indicated decline of oil production of the lease was rapid from February, 1935, to July, 1935. The percentage allowable for the Fairport field was reduced monthly from approximately 75 per cent of the potential rating in March 1935 to 22 per cent in October 1935. In spite of this decline, the production of the lease from July 1935 to July 1938 ranged from 1,033 to 2,518 barrels of oil monthly, which was more than it produced during the year 1932 before the wells were treated." (P. 19.)

"The cumulative production of oil at the end of 1932 was 613,277 barrels for the 80-acre lease—a recovery of 7,666 barrels of oil per acre. At the end of 1937 it was 775,325 barrels—a recovery of 9,690 barrels of oil per acre. Taking into consideration the rate of decline during the period 1927-1932, it has been calculated that by the end of 1937 the total production would have been approximately 655,000 barrels of oil if acid had not been used. Therefore, acid treatment of the wells may be credited with a net gain of at least 120,000 barrels of oil for the lease to the end of 1937, or 1,500 barrels per acre more than would have been possible under ordinary methods of production." (P. 19.)

"EFFECTS OF ACID TREATING IN FAIRPORT FIELD

"The effects of well rejuvenation due to acid treatment are evident in the oil-production figures for the Fairport field. The total cumulative oil production at the end of 1932 was 7,956,263 barrels, and the well average had dropped to 12 barrels per day. If acid had not been used it is doubtful whether any of the 'temporarily abandoned' wells would have again produced oil or whether there would have been any additional drilling in the field. Considering the rate of oil-production decline from 1929 to the end of 1932, it was estimated that the quantity of oil that would have been produced from 1933 to 1937 would have been approximately 2,450,000 barrels. The actual production through the 5-year period 1933-37 was 4,956,082 barrels,

making a net increase of approximately 2,500,000 barrels of oil. If it is assumed that no new wells would have been drilled or old wells returned to production after 1932, when acid treatment methods were introduced, the increase of 2,500,000 barrels for 125 wells is approximately 20,000 barrels of oil per well to the end of 1937. It was also estimated from the production-decline curve for 1933-37 that by about 1940 production will have declined to the average for 1932 but will not reach the older extended decline curve (1929-32) until later. From these decline curves it was estimated that during the 5-year period 1938-42 approximately 1,000,000 more barrels of oil will be produced than if acid had not been used in the Fairport field. This quantity added to the 2,500,000 barrels makes a total increase of approximately 3,500,000 barrels to the end of 1942. Considering 3,600 productive acres in the Fairport field, this quantity represents an increase of approximately 1,000 barrels of oil per acre due to acid treatment." (Pages 19, 20.)

"ACID-TREATING INVESTIGATION IN THE ELDORADO FIELD

"The investigation of acid-treatment records in the Eldorado field did not include all the treatments by the different companies in all the producing horizons of the field because not enough data were available for such a study. However, the records of 266 treated wells were made available for study. These produced from three zones—the Arbuckle (Siliceous) Viola-Wilcox, and Lansing limestones." (Page 22.)

"OIL PRODUCTION

"The estimated production records of 138 wells producing from the Arbuckle (Siliceous) limestone formation which were treated with a total of 229 treatments (an average of 1 2/3 treatments per well) were tabulated and plotted. * * *" (P. 23.)

"Using the rate of production decline from 1924 to 1932, graphic calculations showed that from 1933 to 1937 approximately 667,000 barrels of oil would have been produced if acid had not been used. As 2,457,000 barrels of oil were produced during this 5-year period, there was an increase of 1,790,000 barrels of oil due to acid treatment of the 138 wells to the end of 1937, an average net increase of approximately 7 barrels per day per well over the 5-year period." (Page 23.)

"A large number of wells in the Eldorado field produce from both the Viola limestone and 'Wilcox' sand." (Page 24.)

"The records show that 77 wells producing from the Viola-Wilcox formation were treated 106 times with acid—an average of 1⅓ treatments per well." (P. 24, 25.)

"As a result of acid treatments of wells in the zone, the average production per well increased rapidly during 1933 from 330 barrels per month in February to 690 in December. From the peak reached in 1934, production began to decline gradually. It was estimated graphically, that approximately 1,185,000 barrels of oil would have been produced from this group of wells during 1933 to 1937, inclusive, assuming normal decline of production rates. However, as 2,324,530 barrels of oil were produced during this period, there was a net increase of approximately 1,140,000 barrels to the end of 1937, an average net increase of approximately 8 barrels per day per well over the 5-year period." (Page 25.)

"Forty-nine wells producing from the Lansing formation and two wells producing from the Kansas City limestone (which in the discussion are classed with the Lansing) received 91 treatments, an average of 1 4/5 treatments per well." (Page 25.)

"Using the rate of oil-production decline during 1930-32, graphic calculations showed that from 1933 through 1937 approximately 446,000 barrels of oil would have been produced if the wells had not been treated with acid. As 915,782 barrels of oil were produced during the 5-year inter-

val, the net increase of approximately 470,000 barrels to the end of 1937 resulted from the acid treatment of the 51 wells, an average net increase of approximately 5 barrels of oil per day per well over the 5-year period." (Page 26.)

"SUMMARY OF ACID TREATING IN THE ELDORADO FIELD

"Apparently acid treatment of wells in the Arbuckle (Siliceous), Viola-Wilcox, and Lansing limestone formations in the Eldorado field has increased the ultimate economic recovery of oil from these formations. It was estimated that at the end of 1937 1,790,000 more barrels of oil were produced from the Arbuckle wells than if the wells had not been treated with acid. By the end of 1942 these wells will have produced an estimated 2,690,000 barrels of oil in excess of their estimated production without acid treatment—a net increase of 19,500 barrels per well from 138 wells. This represents approximately 2,400 barrels per acre." (Page 26.)

PX-70

PX-70, Bureau of Mines Report No. 3251, entitled "Engineering Studies and Results of Acid Treatment of Wells, Zwolle Oil Field, Sabine Parish, La.," is in part as follows:

"ACKNOWLEDGMENTS

"Grateful acknowledgment is made to J. A. Shaw, director, N. V. Kinsey, former field agent, and C. P. Dunbar, all of the Louisiana Department of Conservation, as well as to the oil companies and their personnel, who have contributed well records, production data, and geological information. Credit is due the following men for their interest and assistance in the various phases of the work: R. T. Hazzard, G. W. Schneider, W. C. Spooner, H. D. Easton, Wayne Jones, S. A. Thompson, C. L. Moody, R. L. Gay and

associates, H. E. Sullivan and assistants, E. B. Hutson, and R. D. Norton. Thanks are extended to the Standard Pipe Line Co. for production statistics and to the Gulf Refining Co. of Louisiana and the Ohio Oil Co. for well elevations.

"Acknowledgment is made to Dowell, Inc., and to the Ricou Corporation for their interest and cooperation in supplying valuable information and records showing the results of acid treatment on production. H. K. Shearer, engineer and geologist of Shreveport, La., supplied production data and information on the results of treating wells with acid, especially those operated by the Pelican Natural Gas Co." (Page 1.)

"The report was criticized by H. C. Fowler, R. A. Cattell, and H. B. Hill, of the Bureau of Mines; R. T. Hazzard, Gulf Refining Co. of Louisiana; and C. L. Moody, Ohio Oil Co. The part of the report regarding acid treatment was criticized by H. K. Shearer, Pelican Natural Gas Co.; by N. A. Best, Dowell, Incorporated; and by Ludwig Schmidt and John M. Devine, of the Bureau of Mines." (Page 2.)

"GENERAL STATEMENT

"The Bureau of Mines began an engineering study of the Zwolle oil field in June 1930 at the request of the operators and of the Louisiana Department of Conservation. Following the usual procedure in making reports on other fields geological and production data were collected. Special attention was given to obtaining information which might indicate the conditions controlling accumulation of oil in this chalk-rock field. Information also was obtained on development methods and production practices." (Page 2.)

"The pay formations in the Zwolle field are favorable to treatment with acid because of the character of the reservoir rock, which consists of chalks, marls, and limestones that dissolve readily in an acid solution. Many wells with small initial production or with favorable shows have been reconditioned by acid treatment and completed as com-

mercial producers. Treatment of these wells with acid apparently has opened and enlarged existing, minute channelways connected with oil-bearing cavities in the chalk which readily give up the oil through the newly opened drainage channels." (Page 27.)

"PREPARATION OF ACID OR SOLVENT

"Hydrochloric acid of approximately 15-percent strength, to which certain inhibitors had been added to prevent corrosive action on well equipment, was used for treating wells in the Zwolle field. The raw acid, of 19.2° B. (1.1526 specific gravity) and 30-percent strength was shipped to the field station in rubber-lined tank cars. The inhibiting chemicals were added and mixed at the field stations while the acid to 15 percent was being diluted; the resulting solvent, of 1.07 specific gravity was stored in steel tank cars or tanks.

"The corrosive activity on metal equipment of the acid solution when properly mixed with inhibitors has been studied in detail and discussed in published articles.* For proper protection of well equipment the acid should be inhibited sufficiently to allow storage in steel tanks with a minimum of corrosive action. In treating the average well in the Zwolle area the solution is in contact with well equipment a relatively short time, and the complete operation requires only about 2 hours. Proper inhibition is a safety measure and protects the equipment against unforeseen delays which may arise during the treatment of wells. (P. 28.)

"GENERAL PROCEDURE FOR TREATING WITH ACID

"The same general practice was followed by the different contractors in treating wells in the Zwolle field, namely, the solution was pumped into the formation near the bottom of the hole through a string of pipe. In pumping wells the acid solution was pumped down the tubing after removing the sucker rods and standing valve. In other wells either the drill pipe or a string of tubing was used. The procedure is described as follows:

"The casing and tubing (or drill pipe) were filled to the top with oil; the acid pump, mounted on an automobile truck, was then connected to the tubing and the solvent pumped down the hole. When the gage on the acid pump or tubinghead indicated a slight pressure, the valve on the casinghead was 'cracked' to allow the oil to 'bleed' from between the casing and the tubing. A measured amount of oil equivalent to the volume of the tubing plus the volume of the open hole from the bottom of the well to a determined point below the casing seat, was allowed to bleed from the valve; the valve was opened enough to keep the pressure from building up more than a few pounds per square inch, as indicated on the pressure gage. When the predetermined amount of oil had been bled off the valve was closed and the complete acid charge pumped into the bottom of the well. A pressure of 600 pounds per square inch was built up in some of the wells. The speed of the pump was regulated to prevent the pressure from building up higher than 600 pounds per square inch, although the pumping equipment was capable of developing pressures up to 1,500 pounds per square inch. For example, the amount of oil that could be bled from the casing was approximately 16 barrels (672 gallons) in a well 2,500 feet deep, with the casing set at 2,300 feet and equipped with a string of 2-inch tubing. Sixteen barrels is equivalent approximately to two-thirds of the acid charge." (PP. 28, 29.)

"The charge of 1,000 gallons was followed by 10 to 50 barrels of oil, which was pumped down the conductor pipe to displace the solvent and act as a flushing agent to clean the walls of the tubing. Some excess oil was forced into the formation, thus driving the solvent ahead of it. It was the general practice to allow the acid to remain in contact with the formation 48 hours before a production test was made."

"Pressure gages were placed generally on both the tubing and casing-heads. The gage on the tubing in one well under treatment showed a pressure of 120 pounds per square inch compared with a pressure of 375 pounds per square inch on the casing-head. On another well the pressures observed were 400 pounds on the tubing and 650 pounds on the casing. The differences in pressure between tubing and casing recorded in the two wells were 255 and 250 pounds per square inch, respectively. These figures represent approximately the difference in pressures between the 2,500-foot fluid column of acid solution (1.07 specific gravity) inside the tubing and the oil column (0.818 specific gravity) behind the tubing. The pressure at the bottom of the hole was of the order of 1275 pounds per square inch in the first well mentioned and 1,550 pounds per square inch in the second. The gage pressures varied considerably at the different wells, and higher pressures were required in the wells drilled through tight or unbroken strata than in those completed in porous or broken formations. The average time required to pump a 1,000-gallon charge of solvent ranged from 30 minutes to 2 or 3 hours, depending upon the pressures necessary to force the acid back into the formation. Siphoning of the acid solution from the acid truck into the well was observed during the second treatment of the Supreme Oil Co., Pruitt well 1, in sec. 30, T. 8 N., R. 11 W., where a charge of 1,000 gallons was run into the well in twelve minutes." (P. 29.)

"In a letter to the writer H. K. Shearer, engineer and geologist of the Pelican Natural Gas Co., has described in detail acid treatment and results of the treatment of the

Pelican Natural Gas Co., Louisiana Long Leaf Lumber Co. well 16, in sec. 10, T. 7 N., R. 11 W." (P. 29.)

"This well was completed at a depth of 2,627 feet on November 2, 1932, and the casing was set at 2,438 feet. The production for the first day was 60 barrels, then the average daily production ranged from 8 to 12 barrels until December 8, when the well was shut down preparatory to treatment with acid. The rods and standing valve were pulled. The casing and tubing were then filled with 71½ barrels of oil. Sixteen barrels of oil were bled from the casing while the solvent was being pumped into the tubing. The casing pressure 'built up' to 250 pounds per square inch while the acid solution was being pumped into the well, but no tubing pressure was recorded. Following the acid charge of 1,000 gallons, 12 barrels of oil were pumped into the tubing. During this operation a pressure of 150 pounds per square inch was recorded on the tubing, while the casing pressure remained constant at 250 pounds per square inch. After a relatively short time the pressure on the casing and tubing dropped suddenly, suggesting a partial vacuum at the wellhead, as the acid solution flowed into the formation." (PP. 29, 30.)

"The production test began at 3:45 p. m. December 12, about 48 hours after the acid had been pumped into the well. During the first 1½ hours the well pumped 33 barrels; this was followed by 154 barrels in 4½ hours and 376 barrels in 12 hours. The production for the next 24 hours was 666 barrels. The complete production history of this well from the date of completion to January 1, 1934, is given in figure 11." (P. 30.)

"On December 28, 1933 the accumulated production from this well was 110,987 barrels, of which only 336 barrels was produced before acid treatment on December 10, 1932. Assuming that the well would have continued to produce an average of 8 barrels daily until December 28, 1933, it would have produced 2,848 barrels, in addition to the 336 barrels, or a total of 3,184 barrels without acid treatment. The difference between 110,987 barrels and 3,184 barrels is

107,803 barrels, an amount that reasonably may be credited to acid treatment." (P. 30.)

"The increase in production of this well after acid treatment apparently had no appreciable effect on the production of the offset wells. The location relative to nearby wells is shown in figure 11. The unusual increase in production after treatment suggests that a channelway was opened by the acid to an undrained and distinct oil-filled cavity or porous zone." (P. 30.)

"The history of acid treatment of C. H. Tuttle, Byrd No. 3 well, in sec. 7, T. 7 N., R. 10 W., is of interest. The owner and Charles Frink, field representative of Dowell, Inc., gave the writer an account of the treatment. The well was completed September 1932 at a depth of 2,727 feet. The 6-inch casing was set at 2,424 feet. After it had been equipped for pumping the production was approximately 1 barrel of oil per day. The well was treated by the owner with 100 gallons of raw hydrochloric acid without an inhibitor in an attempt to increase production. The raw acid was poured into the tubing and followed by about 50 barrels of oil. A gas pressure of about 60 pounds per square inch was held on the well for approximately 5 days. The treatment resulted in an estimated increase of 8 to 10 barrels per day. In attempting to treat the well later with inhibited acid the tubing was found to be damaged so badly by the treatment with raw acid that it was impossible to pump the inhibited acid into the well under pressure. Some of the acid, however, was forced to the bottom of the hole, and upon bailing some increase in oil was noticed." (P. 30.)

"A new string of 2-inch tubing was run and the well treated the third time. The casing and tubing were filled with oil. The bleeder valve at the casinghead was opened when the acid pumps were started. After an amount of oil equal to the volumes of the tubing and the open hole up to a point near the casing seat had been bled from the casing the valve was closed and the remainder of the acid pumped into the well under pressure. The pressure at the pump immediately built up to 225 pounds, with pressure of 460 pounds per square inch at the casinghead. The acid pump,

was run at full speed while pumping in the remainder of the charge; the pressure at the tubinghead increased to 275 pounds and that at the casinghead to 510 pounds. After approximately three-fourths of the charge had been pumped into the well the pressures dropped suddenly to 125 pounds on the tubing and 360 pounds per square inch on the casing. Following the acid 45 barrels of oil were pumped into the well to flush the tubing and drive the solvent into the formation. The pressures equalized at 300 pounds per square inch on both the tubing and casing heads when the well was closed in for 48 hours. Upon opening for a production test the well began to flow. At the end of the first 12 hours it was producing 38 barrels per hour through a one-eighth-inch choke with 175 pounds back pressure. The choke was adjusted to obtain a production of approximately 200 barrels per day. The 'closed-in' pressure was 700 pounds per square inch. The production from this well declined rapidly." (PP. 30 and 31.)

"RESULTS OF ACID TREATMENT

"An analysis of the production data covering 134 acid treatments in 113 wells showed that the oil production was increased in 62 wells for 30 days or more and that the records of 29 of the wells showed an increase in production of 100 per cent or more for a 30-day period or longer. Forty-one wells, with a combined production of 1,055 barrels per day before treatment, showed a production of 3,902 barrels per day, immediately after treatment, and 2,974 barrels per day after 30 days. The total production of the 41 wells, 30 days after treating, was 282 per cent of the amount before the acid was used. Ten wells had a combined production of 71 barrels per day before treatment, 1,782 barrels per day immediately after treatment, and 1,512 barrels per day (21 times the production before treatment) at the end of a 30-day period. The results of 134 acid treatments are given in table 12." (P. 31.)

* * * * *

"CONCLUSION

"The acid method offers favorable possibilities for reviving oil production, especially in unprofitable pumping wells, and as a 'last chance' in testing 'oil showings' in newly drilled wells. At least a dozen wells in the Zwolle field have been equipped for pumping and placed upon production following the acid treatment that otherwise probably would have been abandoned as noncommercial wells."

"The additional cost of treating a newly drilled well, if warranted by oil showings, does not add materially to the total cost. To January 1, 1934, 623 wells were drilled in the Zwolle area; of this number 361 or 58 per cent were dry holes. Oil showings were recorded in many of these dry holes, some of which might have been treated successfully by acid solution. The seemingly complex reservoir conditions and the irregular occurrences of the oil in the marl and chalk formations preclude definite statements as to the results that might have been obtained in the treatment of the dry holes."

"Although the percentage of oil-well completions in the Zwolle field has remained low since the introduction of acid treatment in December, 1932, the ratio of the number of oil wells completed to the total number of tests drilled has increased from 39.5 per cent for the 13-month period before December 1, 1932, to 47.6 per cent for the 13-month period after December 1, 1932."

"It is possible that the lack of success in some examples of treatment may have resulted from insufficient amount of acid to dissolve the 'limy' deposit on the liner, which in some instances has ranged from one-fourth to three-eighths inch in thickness. It may be advisable to condition wells which are making water for a period of time before treating by pulling the liner and cleaning out the calcareous deposition and sludge material that may have collected in the bottom of the hole before acid treatment, so that the chemical action of the acid will become

more effective in opening new drainage channels or establishing better flow conditions in the old channels after this conditioning."

"In a few wells outstanding results have been obtained by treating with acid. The somewhat spectacular increase in production from these wells has been the stimulus for the general application of the method. It has been used at some time in the majority of the wells."

"At least 150 wells were given 190 acid treatments during the 13 months ended January 1, 1934, at a cost of about $50,000 to the operators. Based on an estimated production of 604,000 barrels of oil due to acid treatment, the return was approximately 12 barrels of oil per dollar expended. During this period the range of the posted price of crude oil was from $0.25 to $1.01 per barrel; and the average, weighted on a daily basis, was $0.66." (P. 35.)

MILLER STIPULATION

(Offered on behalf of plaintiff.)

It is stipulated by and between counsel for the respective parties that if H. C. Miller were called by plaintiff and sworn as a witness, he would testify as follows:

I am a resident of San Francisco, California, and my address is care of the United States Bureau of Mines in that city. I am Senior Petroleum Engineer with the United States Bureau of Mines at San Francisco, and have been connected with said Bureau continuously for the past

sixteen years. I am a graduate of the Michigan College of Mines, now known as the Michigan College of Mining and Technology, and have Bachelor of Science and Engineer of Mines degrees from said college.

I was sworn and testified as a witness at one of the hearings held before a sub-committee of the Committee on Interstate and Foreign Commerce of the House of Representatives of the Seventy-sixth Congress of the United States, held at Washington, D. C., on November 6, 7, 8 and 10, 1939. The following statement appearing at pages 369 and 370 of the Official Report of said hearings, printed by the United States Government Printing Office for the use of said committee, correctly summarizes my said testimony:

"Almost every well drilled into a limestone formation is treated with hydrochloric acid at some time during its pro .ucing life. In areas where daily allowable production per well is based upon the well's capacity to produce and operators desire high initial production rates so that their allowables will be maximum, acid treating usually is part of the well-completion process. In old producing areas, treating wells with acid is for the main purpose of increasing the quantity of oil recovered ultimately from the reservoir. For that reason, wells often are treated with acid at frequent intervals throughout their producing lives.

"Acid treating has had a far-reaching effect on the petroleum industry in that it has effected a complete change of attitude toward limestone production. The spread of development into such limestone areas as western Kansas, Michigan, Illinois, and northern Louisiana may be ascribed in large measure to the success of acid treating processes. Many wells drilled into limestone formations in those areas have been commercially productive of oil and gas only as a result of acidizing. In the newly developed Illinois Basin, for example, many wells drilled into the McClosky formation—an oolitic limestone of varying porosity—failed to show as much as a drop of oil until the formation had been treated with acid. Acid treatment of wells also is credited with extending the productive limits of

many oil fields in which edge wells incapable of producing commercial quantities of oil have been completed as paying oil wells after acid treatment. Furthermore, many fields in limestone areas that had almost reached their economic producing limit have been rejuvenated and their capacity to produce oil increased by treating them with acid.

"Acid treatment of wells to increase the productivity and ultimate recovery of oil and gas is now generally accepted as standard production practice in Michigan, Kansas, Ohio, Illinois, Kentucky, Oklahoma, Texas, and Louisiana, where oil is found in reservoirs of calcareous and dolomitic rock. In some of these areas acidizing has replaced well shooting; or, where the productive limestone formations are very dense, acid treating is used in combination with shooting to increase the production of oil and gas from wells.

"According to Heithecker,[1] acid treating has caused marked increase in the ultimate oil recovery of some old and nearly depleted fields of Kansas, owing to cleaning-out action of the acid at the face of the limestone, enlargement of the small drainage channels, and probably penetration of the acid into previously undrained porous strata. Estimates of greater ultimate oil recovery of various groups of wells in Kansas show increased oil recovery of 10,500 to 21,700 barrels per well, and the increased recovery per acre is estimated at 1,000 to 2,400 barrels of oil; all this has been accomplished by the additional cost of only a few hundred dollars per well for acid and treating service.

"Although it is known that 1,000 gallons of 15-per cent hydrochloric acid will dissolve about 1,800 pounds or 11 cubic feet of limestone rock, there is no definite rule to govern the quantity of acid to be used for treating an oil well. In some wells a single treatment of 1,000 gallons of acid has been beneficial in increasing the rate of flow of oil into the well and in others, according to Heithecker,[2]

(1) Heithecker, R. E., Effect of Acid Treatment upon the Ultimate Recovery of Oil from Some Limestone Fields of Kansas: Bureau of Mines Rept. of Investigations 3445, 1939, p. 41.

(2) Heithecker, R. E., Work cited in footnote 98, p. 5.

as much as 24,000 gallons of acid (volume equivalent to three large railroad tank cars) have been used during stage or multiple treating, the first charge usually being 4,000, the second 8,000, and the third 12,000 gallons.

"The practice of acidizing wells has grown phenomenally in the past five years, and at present about 10,000 wells are treated annually, requiring approximately 25,000,000 gallons of acid.[3] The rapid development of acid treating in recent years may be ascribed to the development of means for minimizing the corrosive action of the acid on casing in the well, improved technique by contract service agencies, and far-reaching results in increased oil production.

"Acid follows the path of least resistance in a well and sometimes enters depleted or thief zones and stimulates the flow of water into the wells. As it is desirable to confine the action of the acid only to the oil-bearing formation organic gels sometimes are used to control and adapt the treatment to special well conditions. This is accomplished by blanketing or plugging with organic gels the formations that acid is not to contact. The organic material is mixed with a type of bacteria to form a colloidal suspension that is pumped into the well ahead of the acid. Within one-half hour the suspension jells, and the well then is acidized while the troublesome formations are protected by the jelly plug. Within 24 to 48 hours, depending on the temperature in the well, the jellylike substance is consumed by the bacteria and liquefied so that it can be bailed, swabbed, or pumped from the well."

The statements contained in the foregoing summary of my testimony before the House Committee were then true and still are true, to the best of my knowledge and belief.

Mr. Lyon: Now, if Your Honor please, one of these special features that he refers to, this jellifying material and all of that, it doesn't seem to me the testimony given

[3] Kiessling, O. E., Rogers, H. O., and others. Technology, Employment and Output per Man in Petroleum and Natural Gas Production. WPA National Research Project, in cooperation with the U. S. Bureau of Mines, Report No. E-10, July, 1939, p. 150.

by this man before this Committee in Congress is admissible in this case here. We have had no opportunity to cross examine.

Mr. Conner: If Your Honor please, we were placed in the position of calling this witness, which we agreed to do, and which we would still do. Counsel, as of May 3, 1941, entered into this stipulation, signed by Mr. Babcock and myself, that he would so testify if he was called. Now they complain of the lack of ability to cross examine.

The Court: I will let it stand. I recognize if he were here I would be asking him well, how much does that inhibitant do? What would happen if you didn't have it? But he isn't here and I can't do it.

Mr. Wilber Owen: I don't know whether Your Honor noted this statement in the testimony of this man Miller. He said: "The rapid development of acid treatment in recent years may be ascribed to the development of means for minimizing the corrosive action of the acid on casing in wells, improved technique by contract service agents, and far-reaching results in increased output."

The Court: If he were here, I would ask him what he meant by "may be." Whether he means he may have been told that, whether it isn't true, or whether it should be ascribed to that. I don't know. I would ask him, any way, if he were here. I think that is a big thing in the lawsuit, gentlemen.

ERLE P. HALLIBURTON,

a witness called by plaintiff, testified as follows by deposition:

DIRECT EXAMINATION

I reside at 19 Berkeley Square, Los Angeles, California, and am general manager of the Halliburton Oil Well Cementing Company. I have been connected with the defendant company since its organization in 1924 and have been its president all of that period. John C. Halliburton is my brother.

The office of the defendant company has been located at Duncan, Oklahoma, at all times since its organization. I would say that the oil industry was responsible for the organization of the Halliburton Oil Well Cementing Company, and that I promoted the organization of that company. At the time of the organization of the company, I owned a controlling interest in the stock, and have at all times either owned or controlled a majority interest in the stock.

I have taken an active interest in the operations of the company at all times since its organization and have been in as close touch with its operations as one individual could. The company was primarily organized for the purpose of cementing and servicing oil wells. Additionally, we controlled wild wells, furnished a general pumping service with our equipment, worked on wild wells and fishing jobs. By wild wells, I mean wells that got out of control, such as those that blew out. By cementing, I mean the use of cement to seal off formations encountered in the drilling of oil wells, the plugging back of wells, and squeezing the formations of wells with cement.

The Halliburton Oil Well Cementing Company has never owned or drilled any wells, or produced any oil. The company's business is rendering the services I mentioned to others who owned and operated the wells and, as time has passed, we rendered additional services.

I, as an individual, had interests in the oil business prior to the date of the organization of the Halliburton Oil Well Cementing Company. Before the organization of the defendant company I engaged in cementing oil wells, and acted in a consulting capacity as an engineer, and drilled a dry hole or two for myself. Before the organization of the defendant company I had owned some small interests in oil wells.

I was engaged in the cementing of oil wells for seven or eight years prior to the organization of the defendant company, both as an individual, as a partner and as an employee of the Perkins Oil Well Cementing Company. So I was pretty thoroughly familiar with the oil well industry and the oil producing industry prior to the time that the defendant company was organized, and had actually worked in the oil fields in California, Texas, Oklahoma, Arkansas, and Louisiana. Some of these oil fields were lime and some were sand. The wells in Oklahoma were lime. I do not believe that at that time any lime formations had been opened up in Louisiana. There had been lime wells drilled in Texas but not in the fields in which I had worked.

My work in the cementing business brought me in touch with the production end of the oil business to the extent that I had put wells on production, but had never really been connected with the actual production of oil. I had worked around and on wells from the time that they had started until they were put on production; that is, began to produce oil commercially. These were wells on which I did cementing, and I have gone in and killed wells where the water broke into the well that had been on production and cemented these wells, that is, shut the water off and then supervised the drilling of the well to put it back on production.

Subsequent to the organization of the Halliburton Oil Well Cementing Company I organized the Steen Drilling Company that drilled a few oil wells. This company operated in Texas and Louisiana, and I don't remember just what official position I held, but I think that I was presi-

dent. The Steen Drilling Company was organized in 1930 or 1931 and was a Delaware corporation. It was a stock company and I owned control of the stock. This company is not now in existence, as it was discontinued about four or five years ago after operating for some three or four years. E. A. Steen was vice president and Phillip Shumway was secretary-treasurer, and I think I was president of the company. This company drilled a few wells in Louisiana, but their principal operations were in east Texas, and we also drilled wells in south Texas; I think the company drilled one well at Port Lavaca, Texas. The company drilled perhaps forty or fifty wells altogether. I would not know the character of the producing formations in the territory where this company drilled. In east Texas, I know the formation was sand. The company did its own drilling and I don't remember that they contracted with others for the drilling of any wells.

I have been connected with another company engaged in the production of oil, Erle P. Halliburton, Inc., which was incorporated about 1933 or 1934. Erle P. Halliburton, Inc. owns production and took over the Steen Drilling Company's production. This company started in the production of oil maybe a year or two after its incorporation. It did not do any producing of oil prior to the time it took over the Steen Drilling Company. It may have drilled a well or two in Oklahoma in 1933 or 1934. I think that about 1933 we drilled some wells at St. Louis, Oklahoma, and I think that it took over the Steen Drilling Company some time after that. The oil wells at St. Louis, Oklahoma, were limestone wells.

Erle P. Halliburton, Inc., has been engaged in the production of oil continuously since its drilling of the wells in the St. Louis, Oklahoma, district. This business has not been very extensive. I have been president of Erle P. Halliburton, Inc. since it was organized. My wife has been a vice president, R. J. Wilbern has been a vice president, John Halliburton has been assistant secretary-treasurer, and James Coe Halliburton has been a vice president. I

have been active in the control of the operations of the Steen Drilling Company and Erle P. Halliburton, Inc. I have been at the head of the business. Sometimes I am afraid I did not keep in as close touch with the business as I should have, but I did endeavor to keep in close touch with the business. Erle P. Halliburton, Inc. is now producing oil in the East Texas field. I think that is the only place that we now have any production. We contracted the drilling of a few wells in Oklahoma, Kansas and Texas. We do have a little production around Houston, Texas, in what I believe they call the Liberty Field.

By Mr. Owen:

Q. In your early experience as an oil producer, what if any method did you follow in attempting to restore production of a well which had been a paying producer, and which had fallen below a point where it would pay? A. It would depend upon the condition of the well and the nature of the formation being produced, as to what you would do, or what was causing the production to decline.

Q. Prior to 1932, did you of your own knowledge know of any instance where the production of a well in lime formation had been increased by any kind of treatment, after its production had decreased for a time? A. You mean the use of acid in the well?

Q. I mean any kind of a treatment that you know of, of your own knowledge, which was applied to a well to increase its production, in lime formation, from lime formation, prior to 1932? A. You mean chemical treatment or mechanical treatment, or what kind of treatment?

Q. Oh, any kind of treatment that you know of. A. Yes, I have re-drilled wells, lots of them, prior to that time.

Q. Just what would you do in re-drilling them? A. Sometimes drill them deeper to a lower horizon, and sometimes plug them back and drill down and shut the water off.

Q. Were any of those in lime formation? A. Some were, yes.

Q. Do you know of any other treatment that was applied to oil wells producing from lime formation, for the purpose of increasing their production? A. Yes.

Q. What were the other methods you have known of? A. I have known of shooting methods.

Q. Explain that. A. Well, take a lime formation and shoot it with gelatin, nitroglycerine, break the formation.

Q. And was that a common practice prior to 1932? A. Yes, I had seen it done prior to that.

Q. Can you name any other method known to you to have been applied to oil wells for the purpose of increasing their production from lime formation, prior to 1932? A. I had heard of methods, but I had had no personal contact with doing it myself.

Q. You have named all those that you had any knowledge of? A. No, not all that I had any knowledge of. As a matter of fact, I had heard of the use of acid prior to 1932; in fact used acid in a well prior to that time.

Q. When did you first use acid in a well prior to 1932? A. Either in December 1919 or January 1920.

Q. Did you do that yourself, in your own operations? A. I did it under contract for E. H. Royer, in the Hewitt Field in Oklahoma.

Mr. Lyon: If your Honor please, if I remember correctly about that, Mr. Halliburton had no records of that particular transaction, and it was related to getting out drill pipe or tools that had been stuck in the well and using the acid to cut that limestone, or whatever it was, that would stick in the pipe or tools, and as we have so many record cases in our evidence, proof of that with full records, we didn't think it was necessary or there was any use of developing just an oral recollection of that, because we have so many of the same things in our evidence.

The Court: That explains why you didn't ask him about it, and I am satisfied.

Q. Have you named all of the methods known to you to have been used on an oil well for the purpose, or with a view to increasing its production, from lime formation, prior to 1932? A. No, I have known of flooding and vacuum, putting vacuum on the formation. I had also heard of putting heating agents, either chemicals or steam, to

dissolve the paraffin and open up the formation for increasing production.

Q. You have named several. Flooding was one. What do you mean by flooding? A. In which you run water into one well and drive the oil to other wells.

Q. What was another one that you named? A. Putting a vacuum on the sand, with vacuum pumps.

Q. That is on sand formation? A. Well, on lime, or any well where vacuum would work.

Q. And how would you do that? A. Well, seal a well up tight at the top, with tubing in the well, and take the production out through the tubing, and maintain a vacuum in the casing, outside the tubing.

Q. What was one of the others that you named? A. I named the use of heat to dissolve paraffin and clean a well out.

Q. Just how was that done? A. Sometimes chemicals were used, and in some cases run steam into the well.

Q. When you used chemicals it was with the view of having or producing heat from chemical reaction in the well? A. Yes.

Q. Do you say that the use of one or more of these various methods you have mentioned was common among oil producers prior to 1932? A. In some fields, shooting was common, and in some fields different methods. You take wells that paraffined up, it was common practice to remove the paraffin in some manner.

Q. Would it be correct to say that the particular treatment which promised the best results in a particular field was the one used there? A. Well, of course different operators would try different things. Of course some producing zones gave up the oil rather freely and the wells never gave any trouble; and then there would be wells in a field where maybe one out of a dozen gave a lot of trouble, and the other wells didn't give any trouble.

With respect to the oil fields in which I have operated either directly or through my companies, it would be hard to say what the average cost of drilling a well would be.

Up to the present time, I have spent anywhere from $3,000 or $4,000 up to $150,000 on a well. With such an investment in a well, it was a natural thing for any operator to do whatever he could to increase or restore production of oil.

I think about 1933 was the first time the Halliburton Oil Well Cementing Company acidized a well. I don't know exactly who we acidized the first well for, and I don't think there was any record kept on the first wells we acidized. I think the first well we acidized was in Burkburnett in 1933. I am not sure as to that date.

Q. Do you know who owned it? A. I don't remember now who owned it.

Q. And you have no record of that treatment? A. No, I don't have any record.

Mr. Owen: Mr. Babcock, has the company any record of that treatment?

Mr. Babcock: Yes, you have got a copy of it. It is referred to in the Chamberlain-McPherson interference. My recollection it was July, 1933, and it was the King Royalty.

The Witness: Yes, that is right.

Not having been on the job and not knowing the nature of the formation, I wouldn't know about the first oil well producing from a lime formation which the Halliburton Oil Well Cementing Company treated with acid for the purpose of increasing its production. For me to state this would be purely hearsay because I didn't go out on any of these jobs.

By Mr. Owen: Will you refer to such documents or reports as you may have, relating to acidizing treatments of oil wells by the defendant company during the year 1933, or the year 1934, or at any earlier date, and point out the first one in which the defendant company gave an acidizing treatment to an oil well which was producing from lime formation, for the purpose of increasing its production?

Mr. Babcock: I have here some acidizing tickets and invoices which have come out of the file of the Halliburton

Oil Well Cementing Company. I do not know whether these are the first—whether these tickets are on the first well done by the Halliburton Oil Well Cementing Company or not. These (indicating) are all our records that I have been able to find up to, I believe, May 1935.

Mr. Owen: And will you state how many different jobs those represent?

Mr. Babcock: Well these invoices are attached to tickets Nos. 1004, 1005, 1006, 1007, 1008, and 1009, and the earliest date is that of ticket 1004, which is March 2, 1935.

By Mr. Owen:

Q. I hand the documents to the witness and ask him to examine them and state which of them relates to an acidizing treatment of an oil well in a lime formation, for the purpose of increasing its production? A. These documents do not state the kind of acid used, or the nature of the formation that was being acidized, but I assume that all of them were lime formation. One of these apparently was not intended to increase production, but was for freeing stuck drill pipe.

Q. Which number is that? A. It is ticket No. 1006. Tickets Nos. 1004 and 1007 also refer to treatments for the recovery of stuck drill pipes.

Ticket No. 1005 shows that the formation was siliceous lime. Ticket 1008 does not seem to disclose the nature of the formation, but I would assume it was a lime formation that was acidized to increase its production. Ticket No. 1009 reports the treatment of a well which apparently was of a limestone formation. I would assume that the formations of the wells referred to in tickets Nos. 1005, 1008 and 1009 were limestone formations. I have no knowledge of these treatments aside from what appears on the acidizing tickets. I think that Joe Verser would have knowledge of these treatments, as I notice his name appears on all three of the tickets Nos. 1005, 1008 and 1009. He would have knowledge of all three of these treatments and the fact that his name appears on them indicates to me that he was present at the treatments. Ticket No. 1005 is the earliest

and is dated March 11, 1935. Ticket No. 1008 is dated May 25, 1935, and ticket No. 1009 is also dated May 25, 1935. These tickets say they used acid and I would assume that it was hydrochloric acid. None of the wells referred to in tickets Nos. 1005, 1008 and 1009 were owned or operated by me or any of my companies.

I think that the Erle P. Halliburton, Inc., records are located in the Houston, Texas, office and not in this office, and that the Steen Drilling Company records are located here, at Houston, Texas, and at Los Angeles, California. I have no personal knowledge concerning any purchases of hydrochloric acid made by either the Steen Drilling Company or Erle P. Halliburton, Inc., from Dowell, Incorporated. I do not know whether or not the Steen Drilling Company or Erle P. Halliburton, Inc., purchased acid from Dowell, Incorporated.

Prior to the treatments of wells reported in acidizing tickets 1005, 1008 and 1009, I think we pumped hydrochloric acid into wells to free stuck tools and drill pipe, but I don't think we have any records earlier than these tickets where we put hydrochloric acid into limestone formations to increase production, and I don't know of any earlier records.

Mr. Owen: And counsel, I understand, doesn't know of any.

Mr. Babcock: None other than you already have. There is a report on that St. Louis well in that same interference file there which you already have.

Mr. Owen: Can you refer to that one, Earl?

Mr. Conner: Here it is, August 1, 1934.

At this point PX-19, 20 and 21, Halliburton Oil Well Cementing Company acidizing tickets Nos. 1005, 1008 and 1009 and the data attached thereto, were offered and received in evidence.

By Mr. Owen:

Q. I show you a purchase order of Erle P. Halliburton, Inc., No. 1234, a typewritten letter dated June 16, 1934, addressed to Dowell Incorporated, Shreveport, Louisi-

ana, and signed in typewriting "Jack Halliburton" and a letter on Halliburton Oil Well Testing Company stationery dated July 22, 1934, addressed to L. A. Prince, Dowell Incorporated at Midland, Michigan, and signed "Erle P. Halliburton, Inc., by Harry E. Hanson," and ask you to examine them and state if you know what they refer to. A. Well, one of the documents is a purchase order, No. 1234, for 1500 gallons of acid, Barr No. 2; I think that was in Louisiana. The other two documents are letters stating where the charge should be made for the purchase of acid. Apparently Dowell Incorporated acidized the Barr No. 2 well with the acid for the Steen Drilling Company.

I do not know who owned those wells, whether Erle P. Halliburton, Inc., or Steen Drilling Company owned them. I think perhaps Erle P. Halliburton, Inc. owned the wells and the Steen Drilling Company drilled the wells for Erle P. Halliburton, Inc., under a drilling contract and Dowell Incorporated did the acidizing job for Erle P. Halliburton, Inc. Jack Halliburton was not working for Erle P. Halliburton, Inc. I think he was working for the testing department at that time. That was just a partnership, Erle P. Halliburton Company instead of Erle P. Halliburton, Inc.

I think that Dowell Incorporated acidized that well on which the acid was used, but I have no personal knowledge of that fact, as I was not on the job. The basis on which I state that Dowell Incorporated acidized the well is because of the purchase order. The order says a 1500-gallon acid job, and I would assume that Dowell Incorporated did a little more than furnish the acid; they must have furnished some equipment with which to pump the acid into the well.

I have examined a purchase order on the stationery of Erle P. Halliburton, Inc., No. 4618, and it appears to be a purchase order for acidizing a well. The order was issued to Dowell Incorporated at their Shreveport district and was signed by Jack Halliburton, and my testimony regarding this purchase order would be the same as that regarding the other order No. 1234, to which I have referred. This last order, No. 4618, looks like the Burkitt No. 3 well. It

indicates that the acid was purchased from Dowell Incorporated for use in connection with the treatment by Dowell Incorporated of one of our wells. I have examined three documents on the stationery of Dowell Incorporated entitled "Bulk material sales receipt," these being receipts Nos. 2081, 2320, and 4513. No. 2081 indicates that we purchased a thousand gallons of acid from Dowell Incorporated. No. 2320 would indicate that we purchased 100 gallons of acid from Dowell Incorporated and bulk material sales receipt dated December 16, 1934, No. 4513, would show that Erle P. Halliburton, Inc., purchased 200 gallons of acid from Dowell Incorporated. I don't know what the acid indicated in these purchase orders was used for. The orders do not give the well number. I should imagine that the acid was used in acidizing some well some place. In the case of such a small quantity of acid as 100 gallons, the acid may have been used to get cement out of a pump.

Here is an Erle P. Halliburton, Inc. purchase order, No. 4509, Dowell Incorporated's order No. 2320, which would indicate that the acid was used at the Barr No. 2 well, and apparently Dowell Incorporated acidized that well.

Mr. Owen: The purchase order No. 1234 and the two letters attached thereto are offered as PX-23, 24 and 25; the purchase order No. 4618 is offered as PX-26; the receipt for acid, No. 2081 is offered as PX-27; the purchase order No. 4509 and the receipt attached thereto, No. 2320 are offered as PX-28 and 29, and the receipt for customer's order No. 4513 is offered as PX-30.

The Witness: I recognize the signatures on these exhibits and they are those of Jack Halliburton, who was connected with Erle P. Halliburton, Inc. at that time.

I have examined what purports to be an agreement between Steen Drilling, Inc. and Dowell Incorporated, and it is apparently an agreement between Steen Drilling, Inc. and Dowell Incorporated, whereby Dowell Incorporated is to acidize two wells located in Sabine Parish, Louisiana. This agreement was signed by Jack Halliburton on behalf of Steen Drilling, Inc. Jack Halliburton was apparently sign-

ing agreements for the company at that time and I guess he was authorized to do this.

(The agreement was offered and received in evidence as PX-31.)

I have examined what purports to be an agreement between Steen Drilling, Inc. and Dowell Incorporated dated April 20, 1934, and it looks like an agreement to have Dowell Incorporated acidize wells for Steen Drilling, Inc. in Louisiana. The agreement is signed by Jack Halliburton on behalf of Steen Drilling, Inc., and I recognize his signature.

(The agreement was offered and received in evidence as PX-32.)

I have examined another agreement dated April 20, 1934, between Steen Drilling, Inc., or Erle P. Halliburton, Inc., and Dowell, Incorporated, to which is attached a carbon copy of a letter dated July 2, 1934, from Dowell, Incorporated, to Steen Drilling, Inc. This is apparently an agreement to employ Dowell to acidize ten or more wells located in Louisiana, Oklahoma, Kansas, Texas, and New Mexico, within twelve months for Steen Drilling, Inc., or Erle P. Halliburton, Inc.

Mr. Lyon: You mean this is to take the place of PX-32, dated April 20th?

Mr. Owen: That is the fact. PX-32 says ten wells in Sabine Parish, Louisiana, and was with Steen Drilling Company alone. And this other was substituted and made with Steen Drilling or Erle P. Halliburton, Inc., and instead of confining it to Louisiana it includes these other states.

The copy of letter from Dowell, Inc., to Steen Drilling, Inc., was offered and received as PX-33, and the substituted agreement was offered and received as PX-34.

Mr. Lyon: Was the contract ever performed, Mr. Owen?

Mr. Owen: Yes, it was.

The Witness: I have examined what purports to be another agreement between Erle P. Halliburton, Inc., and Dowell, Incorporated, for the treatment of a well. This ap-

parently was an agreement entered into between Erle P. Halliburton, Inc., and Dowell, Incorporated, for acidizing a well in the St. Louis field in Oklahoma, and was signed on behalf of Erle P. Halliburton, Inc., by Paul Halliburton.

At this point carbon copy of a letter from Dowell, Incorporated, to Steen Drilling, Inc., dated July 22, 1934, was offered and received in evidence as PX-35, and the agreement last referred to between Erle P. Halliburton, Inc., and Dowell, Incorporated, dated May 10, 1934, for the acidizing of one well in Pottawatomie County, Oklahoma, was offered and received in evidence as PX-36.

The Witness: Halliburton Oil Well Cementing Company is not denying that Dowell acidized wells for Steen Drilling, Inc., for Erle P. Halliburton, Inc., for Gulf, and for a lot of companies.

The first acidizing of wells, in limestone formations for the purpose of increasing their production that I knew of on what we might call a continued commercial basis was information that I secured from different engineers in Tulsa, Oklahoma, about what the Pure Oil Company was doing. Then, soon after that, I heard The Dow Chemical Company was acidizing wells. After that I believe that Mr. Plummer of the Pure Oil Company called me and wanted to know if I wouldn't go into the business of acidizing wells.

I don't remember that I knew just where the Pure Oil Company wells were located. I knew of the use of hydrochloric acid on lime formation, and I had heard it discussed for several years even prior to that. But in these discussions, it was thought that it would be too expensive for the results obtained. I do not know that the first information that I had of actual acid treatments of oil wells was in connection with wells owned by the Pure Oil Company. The first wells that I heard of being actually treated with acid belonged, I think, to the Gypsy Oil Company. I believe an engineer working for them by the name of Wright was down here on some mud problem, and we discussed it. I talked with him personally about the use of acid. I think he said that through the Mellon Institute, the Gulf and

Gypsy Company or some of their affiliated companies had done some experimenting on acidizing.

I would not know the exact date of the first actual information I received regarding the acidization of wells by The Dow Chemical Company or by Dowell, Incorporated, but I would say that this was perhaps in 1933 or 1934. I certainly would have known about it whenever and if they advertised it. I kept in touch with what was going on in the way of developments in the oil industry and a lot of things that were not developments.

I knew that oil wells owned by companies in which I was interested as controlling stockholder had been and were being acidized by The Dow Chemical Company or by Dowell, Incorporated. I think I knew that we acidized a few wells along in 1934, but I do not know to what extent, and I think I knew that we had employed Dowell to do this work, but I didn't discuss the details of the work with the field organization. On the first job or two I did make an effort to ascertain the details regarding these treatments and the results of the treatments.

Mr. Owen: I have here a number of other papers relating to oil wells which were acidized by Dowell, Incorporated, either for Steen Drilling, Inc., or Erle P. Halliburton, Inc. In order to shorten this portion of the deposition, I will identify these documents, and hand them in their entirety to the witness, and ask him to state what he cares to regarding them.

The Witness: A. The documents would indicate to me that Dowell did acidize the wells, about the dates indicated by the documents.

Mr. Owen: I will ask counsel whether any question will be made regarding the fact that these wells were treated by Dowell for Steen Drilling, Inc., or Erle P. Halliburton, Inc., as indicated in these documents PX-Nos. 37 to 66 which have been identified.

Mr. Lyon: We will waive further proof of these facts, subject to either party having the right to correct the record, if the necessity for any correction appears.

(Thereupon PX-37 through PX-66 were offered and received in evidence.)

Q. Did you know on August 1, 1934, what Dowell inhibited acid was, or did you know anything about it? A. I had known for a long time that hydrochloric acid could be inhibited, and naturally I knew what they were attempting to do.

My first experience with the use of inhibited acid was with the Southwest Shipbuilding Company in 1916 or 1917. We used inhibited acid in cleaning steel castings in San Pedro, California.

I don't remember that I made any effort to ascertain what inhibitor was used in the Dowell acid. I do not know whether or not we had the Dowell acid analyzed in our laboratory.

Mr. Lyon: As I understand it, Mr. Owen, there is no issue in this case that the defendant employed inhibited acid up to some time in January, 1936.

The Witness: I am president of both Erle P. Halliburton, Inc., and Halliburton Oil Well Cementing Company. Some of the holdings of the Halliburton Oil Well Cementing Company are in the name of Erle P. Halliburton, Inc., and I think some of the holdings are in my own name. I would not remember what proportion of the stock of the Halliburton Oil Well Cementing Company is owned by Erle P. Halliburton, Inc., but Erle P. Halliburton, Inc., owns most of the stock in the Halliburton Oil Well Cementing Company. I have at all times owned or controlled a majority of the stock in the Halliburton Oil Well Cementing Company.

I would say that George Hoisington had supervision and charge of the acidizing department when the defendant company first went into that business, and I think that the responsibility of the field operations was gradually shifted onto the shoulders of Charles Clason.

GEORGE T. HOISINGTON,

a witness for plaintiff, testified as follows, by deposition:

DIRECT EXAMINATION

My business address is 1212 Union National Bank Building, Wichita, Kansas, and I am district superintendent for The Halliburton Oil Well Cementing Company. I supervise all of the work this company does in my particular district, that is, cementing, acidizing, well logging, formation testing, dump bailer service, sales, flooding and accessory equipment used in and pertaining to all of the above services.

I have been with The Halliburton Oil Well Cementing Company since April, 1924, and have been working on acidizing since about January, 1935. The Halliburton Oil Well Cementing Company first offered a service of acidizing wells sometime, I would say, in the last half of 1934. As far as I know, this service was first offered commercially, on a revenue producing basis, in my district, that was in January, 1935. It may have been before that, but I do not know whether we had any revenue producing jobs before that or not.

My first acidizing job was run for either the Olson Oil Company or The Empire Oil and Refining Company. I do not recall which. I was treating wells for the oil producing companies, and at that time was in charge of The Halliburton Oil Well Cementing Company's acidizing service in Kansas.

If the period when The Halliburton Oil Well Cementing Company first offered acidizing services on a commercial basis dates from the delivery of the equipment specifically designed to do that work, then I was in charge of that service when it was first offered and that was in my district. At the time this service was first offered, it consisted of offering to deliver the hydrochloric acid and

the equipment to put it in the well. We offered a treater, a helper, the equipment and the amount of acid requested by the customer. On the first two or three jobs, we used just straight fifteen per cent hydrochloric acid, with Mr. McPherson's surface tension reducer, as he referred to it at that time. At that time, I used no inhibited acid. During the time that I was in charge in Kansas I used inhibited acid after, I think, the second or third job which was about January and February 1935. The inhibitors used, as I recall, were Nep 22 and Murodine. I believe I purchased the Murodine from Thompson-Hayward Chemical Company, and the other came on request from Duncan, Oklahoma.

We would use the indicated amount of inhibitor that would be required by the volume of acid that we were running. You have a certain proportion of inhibitor in the amount of acid run. In other words, you use twice as much inhibitor in two thousand gallons of acid as you use in one thousand gallons of acid. I do not recall the indicated amount of inhibitor. The inhibitor was mixed with the acid at the time it was loaded out from the storage station.

We used these inhibitors up until the Circuit Court of Appeals handed down the decision in Denver, in the case of The Dow Chemical Company vs. Williams Brothers Well Treating Corporation, which was about 1936. I used the inhibitors, Nep and Murodine, in my district in Kansas from early in 1935 up to 1936, and those are the only inhibitors I recall using during that period.

By Mr. Conner:

Q. Mr. Hoisington, I show you here PX-19, 20 and 21 which purport to be treatments of wells made by the defendant company, and ask you to examine them and tell me if you have ever seen them before. A. I checked all the signatures of each of these. In the treatment of the wells reported in these reports, fifteen per cent hydrochloric acid was employed. I personally did not have anything to do with the treatment of these wells. I recall doing the initial solicitation and discussion and had most of the conversa-

tions with Mr. Hilligoss. These wells were treated in the state of Kansas, which was my district. It was inhibited acid. The inhibitor was either Nep 22 or Murodine. We used an inhibitor on all treatments, and didn't think anything of it, up until the Circuit Court of Appeals' decision was handed down in Denver. There were one or two jobs run, possibly three, in which no inhibitor was used because we did not have it on hand and the customer did not think it was necessary.

Q. Mr. Hoisington, I again show you PX-19, 20 and 21, and ask you to state whether or not an inhibitor was used in those treatments to your knowledge. A. I rather think that it was.

Q. What is your knowledge of the situation as to whether an inhibitor was used in those wells or not? A. It was our policy to use an inhibitor.

Q. And that was your practice at that time? A. At that time, yes, sir. When we would take a thousand gallons of acid out to a location to treat a well with, we used an inhibitor and our surface tension reducer. That constituted an acid treatment when the job was completed.

Prior to the treatments recorded in PX-19, 20 and 21, the earliest of which treatments is dated March 2, 1935, The Halliburton Oil Well Cementing Company to my knowledge on one or two occasions made treatments with uninhibited hydrochloric acid when we did not have any inhibitor. I am quite sure it (inhibitor) was not used on the first job we run.

JOE KINNARD VERSER,

a witness for plaintiff, testified as follows, by deposition:

DIRECT EXAMINATION

I live in Wichita Falls, Texas, and have been employed by the Halliburton Oil Well Cementing Company since September 4, 1923. I have worked for the Halliburton Oil Well Cementing Company in their acidizing department.

By Mr. Owen:

Q. I show you PX-19, 20 and 21, and will ask you to examine them and state whether or not you had anything to do with the acidization of those wells? A. This Hilligoss well, yes, sir, I treated this well.

The Witness: I also treated this Oko Oil and Gas Company well (referring to PX-21). My name is signed to some of the papers on each of the three exhibits. The Hilligoss well was treated first. It was treated March 11, 1935; we used a thousand gallons of acid of fifteen per cent solution. I did not place any inhibitor in the acid used in this well. I do not think we placed any inhibitor in the acid on either of these other two treatments. At that time we were not using an inhibitor. I am sure we were not. I know we did not on this one (indicating PX-19). I do not know where we bought the acid. It was shipped in a car and I unloaded the car. I do not believe it was Dowell acid.

In this next treatment (indicating PX-20) we used a thousand gallons of fifteen per cent uninhibited acid. We used the same type of acid for quite a while. We were using the penetrant in raw acid. I do not know where the acid came from. It came to us in a tank car. I examined the tank car and it had a rubber lining. I remember that the tank car in which the first shipment of acid was received was also lined with rubber.

In the third treatment (PX-21) we used the same kind of acid, that is fifteen per cent uninhibited hydrochloric

acid with McPherson's penetrant. I believe all the acid for both of these tickets (PX-20 and 21) came in the same car, I am pretty sure, because they were run right along the same time, because we had only one tank.

I recall what inhibitor was used at a later date. The first inhibitor we used was Nep 22, that is a trade name; I do not know what the chemical is or its composition. I do not know where we bought it. Mr. Hoisington attended to that, he bought it through Duncan, Oklahoma, or bought it himself, I do not know. The next inhibitor we used was Murodine, but I do not know where we bought it. I do not know how long we continued to use one or the other of these inhibitors, because I stayed in the acid department only until about June or July of 1935 and then transferred to the cementing department.

CHARLES E. CLASON,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I have been employed in the Duncan main office of the Halliburton Oil Well Cementing Company since May 20, 1935. My title has at all times been Superintendent of Acidizing. When I entered the employ of the defendant company it was already engaged in the business of acidizing oil wells. I don't know that they had any orders for

acidizing on hand at that time. I think they had a job the day after, although I was not there. It was up in Kansas, and I was in Duncan. They had in stock acidizing materials at that time. They had muriatic acid or hydrochloric, in a storage tank, and that so-called reducer, and I believe they had some of that Nep compound inhibitor. I don't remember, but it seems to me they had some there in their pump house, at Hutchinson, Kansas. After I went with them they used that as an inhibitor for a time, and then Murodine. They used Nep possibly two months after I went with them and then they switched to Murodine. From hearsay, they used Nep as an inhibitor before I entered their employ. They stated that they had some on hand there. It was carried in stock at that time. I think I saw a drum there that had some in. Probably 50 or 52 gallons, whatever the standard is. It was a liquid. We continued to use what they had on hand, and did not buy any more. We then started using Murodine because it was easier to obtain, as we got it right in Wichita, Kansas, from Thomas and Hayward.

Before I went to work for the defendant, I worked for the Dow Chemical Company twenty years in Midland, and then I think it was about the time I went to Kansas that they organized the subsidiary unit of Dowell, Incorporated. That was in November, 1932. Regarding my duties with the Dow Company immediately prior to the organization of Dowell Incorporated, I was in the acidizing work here in Midland County. I was one of the first to get into that work with the Dow Company. I witnessed some of the early treatments of wells using the Grebe-Sanford acidizing method in Michigan, before I went to Kansas.

When I went to Kansas, I was in charge of Dowell's treating station, and continued in charge of that station for about two and one-half years, roughly. I left the employ of the Dowell Company about May 12th or 14th, along in there some time, 1935, and entered the employ of the defendant on May 20, 1935.

I am familiar with the construction of the steel tanks

used by defendant for transporting acid to the wells to be acidized. The sketch which was made by Mr. J. J. Edwards during the taking of depositions in June, 1939, in this case, looks about the way they would if you looked down inside the top. In the upper figure marked Figure 1 the eight squares marked with an X, are lead plates and they are brazed or soldered to the bottom of the tank. I believe the custom is before those plates, which I think are about 30" square, are put into the tank, they weld a strip of steel or take a strip of steel and braze the edges of these plates to that strip of steel. Now, that is rather a fussy job, attaching that lead to the iron, lead burning, there are a lot of fumes concerned. That can be done in the open. Then when they come to here (indicating) it is a simple matter to spot weld the steel to the steel. The lead plates are put in at the Halliburton shops. We buy steel tanks and then equip them with these lead plates. This line marked A-A' shows the dividing line between the two compartments of the tank, which are not connected so that the acid can go from one to the other. One can be filled and the other empty. These other cross lines between the lead plates probably represent baffle plates. From the bottom they come up eighteen inches, I should say. Possibly a little more. They are to prevent undue slopping of the acid in transportation.

I know something about the electrical treatments that are given to these tanks before they are put into service. We found that when a new tank was put into operation there is a certain amount of current flow until the tank becomes polarized. Now, this current flow results in a deposition, I think, possibly, of lead. At least, it looks like it. I have never analyzed it. But, at least, there is some action there and the tank becomes polarized. Now, that is at the expense of the plates in the tank, and the action comes at the point of contact of the lead and steel. Well, now, naturally, a bare new tank, there is going to be a lot of action there at the start when the acid is put in, when polarization takes place. Now, to alleviate the using

up, you might say, of those lead plates to the extent of where it loosens them, we hung some lead strips in the acid and connected a battery with it to actually deposit this, and thereby not have a job in a very short time of replacing those lead plates. We found that then they would last for a great length of time.

Mr. Lyon: What did you do with the acid that you employed in that polarizing operation? A. That was usually—it may be used, and it might—may have done two things. They have used that acid when it was strong acid, but they have had instructions that it isn't necessary. You could use a weak solution, two or three per cent, and throw it away.

By Mr. Owen:

Q. You mean they have used that acid, used in the polarizing operation, for treating wells? A. That particular tank load could have gone in a well.

In the polarizing operation, we drop down in the manhole of the tank a lead plate which we connect up to the plus side of a battery. The direction of the current flow is from the lead into the acid to the steel and back to the other pole of the battery. The other pole of the battery we connect to the steel tank, as illustrated in figure 2 of this sheet, Mr. Edwards' sketch. I have seen them use for this purpose an ordinary 80 ampere battery such as used to go in Fords. They would let it run down completely. You could see it taking some lead off the lead strip, and that lead goes onto the sides of the steel tank inside. We do that preliminary treatment to prevent too much attack on the lead strips, which were previously placed in the tank. That action comes on the point of contact there.

Mr. Owen: I will offer a photostat of this pencil sketch which was made by Mr. Edwards as PX-71.

(The sketch referred to was thereupon marked PX-71.)

The Halliburton Company stopped acidizing wells shortly after the decision of the Circuit Court of Appeals in the Williams case. That was perhaps in January of 1936. At that time I knew of the Chemical Process Company.

They were in the business previous to that time. I did not know what kind of acid they were using. Previous to that time, January, 1936, I think pretty near everyone used inhibited acid.

Mr. Lyon: Are you testifying you had any knowledge? A. No, that is just an opinion. I don't know.

PX-186, which is entitled Howco Method of Protecting Tubing and Casing against corrosion while acidizing a well, and which bears the date March, 1937, on the title page, was published quite a little time after defendant started acidizing again. I think this was the first published announcement, but I think they had actually started in business before this was published. I think it was in June, 1936, they started using that Menaul method.

During that period from January to June the Halliburton Oil Well Cementing Company was out of this acidizing business entirely, for this purpose.

CARL A. NICHOLAS,

a witness called by plaintiff testified as follows, by deposition:

DIRECT EXAMINATION

I am 31 years old and employed by the Halliburton Oil Well Cementing Company as a treater. I supervise acid treatments of wells made by that company, and, at present, am located in the Salem oil field in Illinois where I have

been since about the first day of May, 1939. I have been employed by Halliburton since December of 1936.

From April 20, 1938, until February, 1939, I was stationed at Mt. Pleasant, Michigan and worked for the Halliburton Oil Well Cementing Company in the capacity of a treating engineer in charge of acidizing oil wells. My job was that of supervising the acid treatments given to oil wells by Halliburton, and I checked the field and also solicited business. The Halliburton Oil Well Cementing Company, at Mt. Pleasant, Isabella County, Michigan, maintains an office with a telephone listing and a treating station from whence they acidize oil wells.

At the time I was located at Mt. Pleasant, Halliburton had two combination units, which handled both acid and cementing, and equipment for transporting acid to the wells. At Mt. Pleasant, Michigan, Halliburton also had two acid storage tanks which were located just back of the Sun Oil Company's bulk plant, right across from the Isabella County Railway yards on the north side of town. These storage tanks were made of wood and had a capacity of 250 barrels each.

As to the various services and materials which Halliburton offers to the petroleum industry in connection with acidizing oil wells, I am familiar only with those services and materials that I used. I am familiar with the type of acid used by Halliburton and know that hydrochloric acid of 15 per cent is used when acidizing oil wells. I obtained all of my experience as an acid treating engineer after having come to work for the Halliburton Oil Well Cementing Company.

I am considered to be an experienced treater and am sent out to a well and given full charge of treating that well. As a rule, I do not have any assistance in treating a well other than truck drivers who drive the trucks to the well location and do the necessary work of hooking up various pipes and pumping the acid into the well. I supervise the job.

When I was located at the Mt. Pleasant Station of the

Halliburton Oil Well Cementing Company, I had occasion to treat wells in Ogemaw, Arenac and Gladwin Counties, Michigan. When treating wells in these counties the acid employed would come from Halliburton's station at Mt. Pleasant, Michigan. To my knowledge, I never treated any wells in these counties wherein the acid did not come from Halliburton's storage at Mt. Pleasant, Michigan. In treating an oil well, as a rule, I would be present when the transport tanks were loaded with acid from the storage tanks. In treating a well the first thing we would do would be to get our truck drivers together and then load the acid transport tanks with acid. Water was always first loaded into the acid transport tank, and then 20 per cent Baume acid was added to this tank from the storage tanks at Mt. Pleasant.

Then, of course, we had to make the trip to the well location and after that, the first step in treating the well would be to load the well hole with oil. Then, you would proceed with your acid treatment by putting your acid into the well. The usual procedure is to bleed off oil until you have your formation covered with acid and then you close in the well and force the acid into the formation. The tubing and open well hole is flushed with oil so that all of the acid is forced into the formation. Pressure is used in order to force the acid back into the formation. When we arrive at a well to treat it, we would have a truck with a pump mounted on it, and the truck would be pulling a trailer containing an acid transport tank.

The truck driver or drivers and myself make all necessary pipe connections to place the blanket, acid and oil in the well hole. Employees of Halliburton make these connections, and operate the pump to put the blanket, oil and acid into the well. All operations relative to treating a well with acid are done by Halliburton employees, and when anyone other than myself does any work in connection with treating a well, that work is done under my instructions and supervision.

Part of the hydrochloric acid used by the Halliburton

Oil Well Cementing Company in treating oil wells in Michigan came from the Pennsylvania Salt Manufacturing Company at Wyandotte, Michigan, and the rest of the acid came from the General Chemical Company at Norwich, a suburb of Chicago, Illinois. The acid was shipped to us in rubber-lined tank cars. Part of the time I unloaded the acid from the tank cars and put it into the Halliburton storage tanks and part of the time some of the other employees of the company performed this operation. I checked the unloading of this acid, and when a tank car of acid was received I was responsible to Mr. Edwards for its unloading. As a rule, when a tank car of acid was received at Mt. Pleasant it was unloaded that same day, and put into the storage tanks. That was our usual practice. When we used this acid to treat wells, it was diluted with water.

The formations from which the oil wells in Michigan produce oil are limestone and dolomite. I know the action that hydrochloric acid will have on calcium carbonate and on typical limestone formation. The action is such that the acid will consume a certain percentage of the calcium carbonate, and that is the reason we used hydrochloric acid in treating these limestone formations in Michigan. By pumping the acid into the formation under pressure you merely open channels in the limestone which are formed by the acid spending itself on the formation. Whether or not it is necessary to allow the acid to remain in the formation any length of time depends entirely upon the formation. Some formations are fast reacting when subject to the acid and some react slowly. The length of time that the acid is allowed to remain in the formation sometimes varies from an hour to several hours.

When I received the acid from the manufacturer, I made no tests or analyses of it. When I took it out of the storage tank prior to putting it into the transport, no tests or analyses of the acid were made at that time, nor were any tests or analyses made at the time it was put into the transport tank and before it was put into the well. When the acid was taken out of the storage tank and prior to

putting it into the acid transport tank or after it was put into the transport tank but before putting it into the well, I usually tested the acid with a hydrometer to check it to see if it was 15 per cent strength treating acid. The only tests I made at any time between the time I received it from the manufacturers and the time it was used in acid treating a well was merely a test made with a hydrometer to determine the strength of the acid. With respect to the materials employed in treating wells in the counties of Ogemaw, Gladwin and Arenac, Michigan, no tests were made of these materials just prior to putting them into the well. I did not save any samples of these materials. There were some instances where the operator saved samples of the acid. What he did with them I do not know. I made no tests or analyses of the acid while it was being retained in the storage tank at Mt. Pleasant, Michigan. To my knowledge, no samples of that storage acid were retained and I never retained any specimens of that acid and saved them. It has never been my practice to make such tests and to take such samples while the acid was being retained in the storage tanks at Mt. Pleasant, Michigan, and I never saw or heard of anyone doing it.

I am familiar with and know the construction of the equipment employed by the Halliburton Oil Well Cementing Company in acidizing wells. The acid transport tank is a steel tank and is built on a trailer. Those used in Michigan are constructed with two compartments of 500 gallons each and have baffle plates crosswise and lengthwise in each compartment. These tanks have lead plates bonded in them, and there is a dome in the tank for filling it. The tank has a suction manifold with two connections, one leading to each of the two interior compartments. I believe there are four lead plates bonded to the bottom of each interior compartment of these transport tanks. I do not know the exact size of these plates. I believe they are about 30 inches square, and that there are eight in all in each transport tank. These plates are about one-eighth inch in thickness.

When treating an oil well with acid, aside from the pipe connections that extend from the pump or acid tank to the well tubing, there is another connection which comprises a heavy electrical bronze cable, one end of which is connected to the acid transport tank and the other end to the well tubing or casing.

I have acid treated better than 100 wells in Michigan and they were all treated by me while working for the Halliburton Oil Well Cementing Company. When we first went in the acidizing business at Mt. Pleasant, Michigan, the original acid transport tanks were there before I arrived. Some Ford transports arrived at Mt. Pleasant after I was there and they had tanks on them for transporting acid.

Before utilizing these tanks for transporting acid, they were electrically polarized and there was one or two of these tanks that came to Mt. Pleasant, Michigan, that had not been electrically polarized. These tanks were polarized by using 15 per cent acid and extending lead strips down into the acid. These lead strips I refer to are additional to the eight lead strips which are bonded to the bottom of the tank compartments. The additional lead strips are put on a wooden frame that sets across the dome of the tank, and they are connected to the tank through a storage battery which is then allowed to lose its charge in that process. Now, as to what happens there, I would not be able to tell you. I merely followed instructions as to what was to be done. I helped position these additional lead strips in the tank. Only a portion of these additional lead strips was immersed in the acid, but they were not in contact with the walls or top side of the tank, but in contact with them only through the battery. By means of wires, I helped to make the connections connecting the battery up with these additional lead strips on the inside of the tank. I saw this done. We used an ordinary six-volt storage battery.

When I would treat or supervise the treatment of wells in the counties of Ogemaw, Arenac or Gladwin, Michigan, I would make a record and report of that treatment to the Halliburton office in Mt. Pleasant, which consisted of a

data sheet, in the form of a work order. This was always made out before the acidizing job was done and was signed by the operator or the well owner's representative. We kept an acidizing ticket as a record of the well treatment. The acidizing ticket showed the time involved in making the treatment and the pressures required or actually used in forcing the acid into the formation. The acid ticket further would show that the well was treated by the Halliburton Oil Well Cementing Company, would give the date of the treatment, the address of the party or well owner for whom the treatment was made, the position or location of the well as to the lease, well name, section, township, range, state, county and pool, where such information was available. The acidizing ticket also gave the time that our equipment arrived at the well, together with the numbers of the equipment to identify it, the distance of the well from the station making the treatment, the amount of oil used in treating the well, the number of pumps used in placing the acid, oil and blanket or other material used into the well, and also indicated on this ticket was the time when the acid was placed in the bottom of the well.

The table entitled "Pressure Record" appearing on the acidizing ticket is for the insertion of figures in the time column to show the length of the treatment. This column will indicate any changes made in the treatment with respect to the volume of fluid and the pressure required to force it into the well. Any time there is a change in the pressure or change in the directions of treatment in any way, that is recorded on this record. Under the headings "Time," "Vol. acid in," "Casing" and "Tubing" (the last two headings under "Pressure") at any given time show the amount of acid in the well at that time. The next column to the right shows the pressure on the casing and on the tubing, together with the amount of acid in the well. The acidizing ticket further shows the amount of oil used to flush the well and the pressure on the casing and on the tubing at the end of the treatment; and the ticket further shows the materials used and the charges made therefor by the Halliburton Oil Well Cementing Company.

At the bottom of the acidizing ticket appears the word "treater," at which place the Halliburton treating engineer would, as a rule, in his handwriting, insert the name or names of the Halliburton men helping him. Over the line marked "Owner of well or agents" the well owner or his agent signs his name. The acidizing ticket is further filled out to designate which of the Halliburton treating stations is rendering this acid service. The well owner or his agent is given a copy of this acidizing ticket. It was my practice while employed by the Halliburton Oil Well Cementing Company at Mt. Pleasant, Michigan, and when making acid treatments to fill out such a record as I have been discussing, which record is entitled "Acidizing Ticket."

I have examined the acidizing ticket No. 6581 of the Halliburton Oil Well Cementing Company, and this ticket is a report on a well which I treated. The well was treated for the Chapman Oil Company, April 27, 1938, using a thousand gallons of penetrating acid and 4 gallons of blanket. The well treated was the State Well No. 2 located in Midland County, Michigan. I was the treating engineer in charge of acidizing this well, and this well was treated for profit. I have also examined acidizing ticket No. 6583 of the Halliburton Oil Well Cementing Company, and this record indicates that bean powder and blanket were used in treating the well listed in this report. I have also examined the acidizing tickets Nos. 8184, 8185, 8188 and 8196 of the Halliburton Oil Well Cementing Company.

Mr. Owen: Your Honor, these last tickets are the treatments that are involved concerning which infringement is charged.

Mr. Lyon: I didn't quite understand the statement of Mr. Owen. What is there in particular about these four tickets?

Mr. Owen: These are the tickets which relate to the treatments from which the samples were taken upon which the charges of infringement are based.

Mr. Lyon: We are going to object to any evidence in regard to those treatments, the samples, if they are relied

upon to establish infringement because their position is—I don't think it is contested—that those wells were acidized and the treatment performed with the consent of the plaintiff. Of course at the plaintiff's instigation, and the plaintiff cannot sue, and Halliburton is not liable as an infringer for carrying out Weber's request, or what Weber had been authorized to do by the Dow Company. We object to the evidence of those wells. I don't think you deny that the Dow Company authorized the Weber Company to hire Halliburton. We object to that. I don't think you deny that the Dow Company authorized the Weber Company to hire Halliburton to perform those treatments.

Mr. Owen: I am perfectly willing to state to the court just what took place. Plaintiff had for some time endeavored to secure evidence of just what the defendant was doing, just what it was using. The manner and nature of this business is such that they had no means of ascertaining when the Halliburton Company was to make a treatment. They couldn't get that information from the Halliburton Company. They had no means of knowing when or where Halliburton was to make a treatment, and therefore, in order to secure samples of the materials that were being used by Halliburton, the representative of The Dow Chemical Company, or of Dowell, I don't know which, arranged with the Weber Oil Company to secure a certain number of treatments from the Halliburton Oil Well Cementing Company and to take samples of the materials used which were to be delivered to plaintiff, and that was done.

The Court. Who paid for the job?

Mr. Owen: So far as the transaction between Halliburton and the Weber Oil Company was concerned, the Weber Oil Company paid for it, although the Dow Company reimbursed the Weber Oil Company but Halliburton didn't know that.

Mr. Lyon: How do you consider that an infringement?

The Court: The plaintiff gets something that is infringed in the trade, and goes around and buys things, I suppose, to catch the claimed infringing defendant, and I

have never had that question raised before. I suppose they could say in all those cases, a bolt or nut claimed to be infringement made by the defendant, and they get some retail fellow out in the country somewhere to order it.

Mr. Conner: If Your Honor please, at this time it seems that defendant finds itself in this position, that here they are in Mt. Pleasant, they have a place of business, they are acidizing wells, they are accepting such business, they are trying to get this business. Now, merely because they treat wells for these particular people, they maintain under that circumstance,—and we get evidence of what they are doing, that that is not infringement; but, you must not fail to see that they are taking all the acidizing business they can get, and doing the same thing on each and every well.

This thing of treating a well is a very hard thing, usually. I don't know how much business they get, but in order to get evidence of the infringement,—it is not a material thing, it is not solid, it is a method claim, and in order to get evidence whether they are infringing or not we have to be right there and watch every single step they take, and how they do it, and what they do it with.

We arrange for these treatments. We ask Weber, will you get some treatments from Halliburton. Does Halliburton have to take those treatments or not? All they do is accept that business in their normal course of their everyday operations.

The Court: I was trying to say, but I was interrupted, it is just the usual thing that I get in all cases. This is the first time I have ever had this question raised as to whether most of them prove the infringement. If there is any difficulty at all they get some people that are engaged in business out around that are friendly to the plaintiff, the patent owner, to order some of these things. I don't suppose when we come to an accounting, perhaps, that they include that at all. I don't know. But, they do the same thing in criminal cases.

Mr. Conner: I want to get in here there is no such

thing here as entrapment. There is no question of entrapment.

The Court: They don't claim entrapment. We are right in this building. We will say this building and every other post-office building is built with peek-holes so that they can watch the clerks, and the clerks all know it, but in spite of that once in a while they are so tempted by a letter they see money in, they take it. They haven't the right to send those things through the mail, put temptation in their way; they haven't a right to go and coax somebody that isn't violating the law to become a violator. Then you get over into the inducement, and I never liked the word, because I always understood you always had the right of setting a trap, and they do it in criminal law. They set a trap. And, they fall through it if they are regularly in the business. They do it with bootleggers. You could go to a man who is making moonshine and coax him to go and make you some, and offer him good money, and he goes. The officers of the law do that. That is putting temptation in the way of an honest man.

But if he already is doing the thing, and you just try to get proof of what he is regularly doing, then I understand you have a right to do it. You didn't do this different because they did not specifically ask you, as I understand it, to put certain things into it and do it in a particular way.

Mr. Lyon: Well, they asked us to put the blanket in.

The Court: What?

Mr. Lyon: They asked that the blanket be put in for one thing. I haven't finished my explanation of my point, if you please, if I could.

In the first place, there is a principle that jurisdiction in the Federal Court cannot be established by collusion, and in this case the Halliburton Company is not an inhabitant of the State of Michigan or of this District. In order to establish venue in this case, the defendant, as I understand it, relies upon these particular four wells—or the plaintiff does. And, to prove infringement, Halliburton Company

not being an inhabitant of this district, it can only be sued if it has a principal place of business here, which it has, and has infringed here.

The Court: Yes.

Mr. Lyon: Now, then, to prove that infringement, which is denied in the answer, the plaintiff relies on the collusive transaction here between this Weber Oil Company and the other oil company, the Petroleum Investors, Incorporated. And they say, "Here, Halliburton, you have infringed because you have treated these wells for these companies."

Now, that couldn't have been an infringement unless the Petroleum Investors Company and the Weber Company were infringers. The work orders which are here in evidence under which this work was done provide as follows, typed on each one:

"Also it is necessary in work of this nature to depend largely on indicated conditions in a well and there being natural uncertainty as to measurements and variations of formations to be treated it is expressly agreed—" these were signed by these oil companies and Halliburton— "—first, that Halliburton Oil Well Cementing Company makes no guarantee of the effectiveness of the materials to be used in the treatment of the well nor of the results of the treatment.

"B. That it shall not be liable for any injury or damage to the well growing out of or resulting from the treatment of said well or from the use of said equipment in doing said work.

"C. Halliburton Oil Well Cementing Company only agrees to furnish the materials here on order and any equipment suitable for placing said materials in said well and two operatives to assist in performing the work under the supervision of the owner of the well or his representative."

So, unless the owner of the well, the man for whom the work was done, was an infringer, Halliburton can't be a contributory infringer or joint infringer. You can't be a

contributory infringer unless you contributed something to such infringement, or you can't be a joint infringer unless there was another joint infringer, and in this case these oil well companies were authorized by the Dow Company to do this very job. They had their permission.

This isn't a question of entrapment. We are coming down to the question of whether or not this is a legal venue of these four cases, if they can be used to establish venue here, because they were by collusion. And if Your Honor hasn't read it I would suggest you consider the decision of Judge Westenhaver in Southern Textile Machinery Company vs. Wovenright Knitting Company, 44 Federal Second 234, a decision he wrote in 1925 under this venue statute in patent cases, dismissing the case because there was collusion in establishing the venue. The plaintiff went in there and colluded with the person to establish the sale in that district.

The Court: How about this line of reasoning, though: The proof already shows that they probably have treated 100 wells in this jurisdiction here. Now, then, they analyze only four wells, and your objection, if you are limiting it to that question of collusion—but how about taking that as very good circumstantial evidence of the fact that all of those wells that you have been treating here were of that kind?

Mr. Lyon: Well, my objection is based on this, Your Honor, because I asked Mr. Owen what he relied on those four wells for, and he said those were the four he was relying on to establish infringement.

The Court: But I realize that he relies on those four, and then I don't know whether he does or not, but I would assume that circumstantial evidence as to the others—in other words, suppose I found against you all the way through and you finally got around to the accounting, the court wouldn't stop with an accounting as to only those wells they analyzed, but they would use that as circumstantial evidence of what was done in the other cases, I think.

Why not use that in the same way as to this? I don't

see as they are limited to the four wells they have analyzed. That is all they have analyzed and from that they draw certain conclusions. You take—oh, I don't know whether I can think of a good example or not, but we have it all the while. We go into- -well, take the ordinary bootlegging case, you go in and they see them selling drinks right along, they watch them for a while, and they are selling drinks. They go in and they buy only one drink, but you reach the conclusion that they are bootlegging to the others because of what the one got. He will ask for the same thing, the same thing he hears them ask for.

Mr. Lyon: I see Your Honor's point all right, but I don't see what it is going to lead us to, because the proofs so far as they have disclosed in the preliminary depositions in this case, I can't tell whether they charge that on these four wells something was added to these acids, some minerals were put in the acid or some inhibitor put in. They present certain analyses of the acid before and after. Now, we asked them if they wanted to stipulate if what was done on those four wells was typical and representative of what was done on the other wells they were treating in Michigan, and they refused to stipulate.

Mr. Owen: No, we didn't have any such proposition, and I am perfectly willing to stipulate to that.

The Court: They certainly can't get any stronger conclusion unless they prove something.

Mr. Lyon: If they are going to contend that on those four wells somebody put something in the acid, which we say we did not do, and those jobs were done at their request, the evidence shows, for instance, that in connection with the well for the Petroleum Investors, one of the four they rely on, that as a matter of fact the Dow Company had a man there in the field who told them what they wanted done, and directed the treatment of the well as to the putting in of the blanket, and so forth, and the Halliburton people thought he was a representative of the Petroleum Investors, but he was a Dow man.

If they are going to rely on any finding of iron or

copper or anything else in these acids, we are not willing to stipulate, and I don't think the court should infer from that that there would be such things in the other wells, as they say that that proves that somebody put something, some copper or some lead or something into the acid.

If they are willing to take our statement that no such thing was done, why then, of course, we are not so much concerned about this point, but what we are concerned about at this point is that if they are going to argue that something peculiar, something beyond what we admit we did here in these four wells occurred, they are going to rely on these four wells and their analyses on these four wells to establish their infringement, we want to reserve the point that those four wells are not infringing wells.

The Court: Well, I will overrule the objection, and you have got your exception to it, and whether I have got circumstantial evidence that leads to some certain conclusion or not, I will have to wait until I have heard all of the evidence and all of the circumstances and every other kind of evidence. But I think that fully protects your record and I will let them go ahead. I will overrule the objection.

Mr. Owen: I would like to state this for the record, Your Honor, that the plaintiff is relying upon what we found in the acids from these wells, and what the defendant did in treating those wells, as representative of the treatments that they were giving throughout this district, and that if the acids of which we took samples, and those particular treatments, are infringements, we will contend that all of the other treatments made during the same period, by the defendant company, in this district, were also infringements.

The Court: I will hear the proofs. They probably will be telling me about what was done there, and how it was done, and what was done in other places, before they are through. Anyway, I will hear the testimony.

You may go ahead.

The Witness: I have examined the acidizing tickets

Nos. 6581, 6583, 6585, 6587, 6589, 6592, 6594, 8161, 8167, 8176, 8184, 8185, 8188, 8196 of the Halliburton Oil Well Cementing Company, and these tickets are reports on wells which I acidized or which were acidized under my direction, as a representative of the Halliburton Oil Well Cementing Company. I was the treater in charge of acid treating all of these wells referred to in the above tickets. These wells were treated in the State of Michigan from the Halliburton Oil Well Cementing Company's Mt. Pleasant station. The wells which were treated and reported in the acidizing tickets Nos. 8184, 8185, 8188, and 8196 were treated by the Halliburton for the Weber Oil Company. These wells were located in Ogemaw County, Michigan. There is data on these tickets which indicates whether or not we employed pressure in connection with placing the acid in the well. The pressure indicated on these tickets shows the pressure it took to pump the acid into the formation. I put the acid back into the formation, or rather, I endeavored to put it back into the formation. So far as I know, the data on these tickets truly represents all of the facts relative to the actual treatment of the well. These tickets also give the location of the well and the materials employed in treating it. The acid was forced into the well by the application of pressure and the well was closed in so that the acid could not come out of the well. I do not remember exactly how long the acid was allowed to remain in the well, but it stayed there a few hours possibly. The acidizing tickets do not indicate how long the acid stayed in the well.

Acidizing ticket No. 8188 shows that a two-stage acid treatment was given to this well and that after the first stage was finished the acid was allowed to stay in the well for a short time. I would not attempt to say how long the acid stayed in the well, and the acidizing ticket does not indicate this. As indicated on the acid ticket No. 8188 between the time of 11:38 a. m. and 2:30 p. m. the acid was allowed to stand in the well a while, and then the well was swabbed and cleaned up. The second stage of the treat-

ment then proceeded, commencing at 2:30. After the second stage of the treatment, the acid was allowed to stand in the well for a while, but how long I could not say. This was done under the supervision of the superintendent of the Weber Oil Company and he took care of that himself. He told them how long to leave it set and how long to swab it. This acidizing ticket No. 8188 reports on a three-stage treatment.

I have examined aciding ticket No. 8184 of the Halliburton Oil Well Cementing Company and, to my knowledge, this ticket is a report on the first well acidized by Halliburton for the Weber Oil Company. At the bottom of the ticket appears the name W. L. Steelman, whom I contacted with respect to this well, but I do not know exactly when. He was in charge of this Stella Wilcox well. I treated the Stella Wilcox well as indicated on these acidizing tickets on two different occasions, namely, on August 2 and on August 5 of 1938. I can not tell by reference to these tickets whether or not this well had been acidized before. I would have been told by the well operator, as part of my knowledge preparatory to treating the well, if the well had been previously treated. I cannot say whether that well was acidized by anyone else prior to August 2, 1938, when I acidized it for the first time.

When treating the Weber Oil Company's Wilcox well on August 5, I used 2000 gallons of acid and 25 barrels of oil to flush the acid and with which to push the acid back into the formation. When I finished treating this well, the acid was allowed to remain in the well for a short time. I do not know how long. To get the acid out of the well, the well was swabbed by the Weber Oil Company.

By Mr. Conner:

Q. At your completion of acidizing that well on August 5, could the satisfactory acidization of that well be effected without swabbing or withdrawal of that acid? A. What I can't understand is what you mean by that. It has got to come out.

Q. The acid must come out of the well in order to

satisfactorily acidize that well, is that correct? A. Here is the thing, the well has to be produced. And in order to produce it, you are going to have to remove the fluid. When they go in there to produce a well, as far as whether the treatment is successful or not, the time that is left before it is put on production is probably immaterial as to the results of the treatment.

Q. You stated as far as you knew this well had never been acidized before? A. I could not say. I don't remember and I could not tell by looking at this ticket here.

Q. Then, as acidizing treating engineer, when you finished the acidization of that well, as reflected by that ticket, for the Stella Wilcox on August 5, what if any instructions did you give Mr. Steelman, as the operator, relative to putting that well back on production, with respect to the withdrawal of any spent acid or fluids in the well before the well could be produced again and production from that well put into the production lines or tanks? A. Well, to my knowledge I gave him no instructions, because I worked under his instructions on those jobs, and in this particular case there, Mr. Steelman told me what he wanted done, instead of me making any suggestions. However, had it been against the ethics of treating or anything, I probably would have made some suggestions, but in this particular case I gave him none that I know of.

Q. You testified that you have treated some 200 or more wells, is that correct, with acid? A. Yes, sir.

Q. Now, is it now necessary, after putting the acid into the well and forcing it back into the formation with oil, and after the well had been shut in for a period, to then remove the spent acid or fluids from the bottom of the well before the well is put back on production? A. In most cases, yes, sir.

Q. All right. When you were treating a well for an operator, who had never had a well treated before, did you not instruct the operator as to what should be done in order to put that well back on production? A. I merely gave him suggestions of what other operators have done. After

all, either the operator or some representative of his usually has some knowledge of the acid business.

Q. Then, removal of the spent acid is a necessary step to the acidization of a well, is it not? A. Surely.

Q. This spent acid must be removed, is that correct? A. In lots of cases you don't get your spent acid back.

Q. But if it is there and can be gotten back, it must be removed before the well is producing again, is that correct? A. Some wells are put right on production without removing this spent acid.

So far as I know, the acidizing tickets that I have referred to are the most complete records relating to the treatments of the wells reported in these tickets, I made all of the entries recorded in these tickets and, to my knowledge, they are true. I did not retain any specimens or samples of the materials employed in treating the wells recorded in the acid tickets Nos. 8184, 8185, 8188 and 8196. I do not know whether anyone else in my organization retained any specimens or samples of the materials used in treating these wells. I made no tests or analyses of any of the materials employed in treating the wells identified by these four tickets, and I do not know whether anyone else in my organization made any tests or analyses of these materials. I did not make any tests or analyses, and so far as I know, none of the other employees of Halliburton made any tests and analyses of the particular materials used in treating these four wells.

Neither I nor anyone else in my organization, to my knowledge, made any tests or analyses of the materials used in treating the wells referred to in the other acidizing tickets, and neither I nor anyone else in my organization, to my knowledge, retained any samples or specimens of the materials employed in treating any of these other wells.

Q. Did I not understand you to state that after you and your crew had finished operations of putting the acid in the well, that you, in some instances and on some occasions, made suggestions to the operator relative to what should then be done with the well in order to put it back

on production? A. There are some cases when the operator and his employees are not familiar, and I merely suggest policies followed by other companies and their employees.

Q. What are those suggestions you made on those cases? A. That would depend entirely upon the situation to be covered.

Q. What suggestions of any type have you made to the operators under those conditions? A. Well, that would be awfully hard to say. I could not go back and recall them.

Q. Can't you give an example of such a situation? Did you not tell him what should then be done with the well in the event he did not know of it, in the instance we are now speaking of? A. No, sir, I would not want him to use my word as authentic.

Q. Can you give us no examples of such suggestions as you stated you have made to operators in such cases? A. No, I could not, for the simple fact that most operators have their own ideas about that. I can't recall any instance, where I told them a set rule or gave them any instructions to follow.

Q. You do know, though, that in order to satisfactorily conclude the acidization of a well, that the spent acid, if it is there and be removable, must be removed, do you not know that to be a fact? A. Surely, it should be removed. I know that from practice.

Q. And you do know, as a matter of fact, that the spent acid is removed, be it removable from a well after it has been acidized, whether you acidize it or anyone else, is that correct? A. Here is the thing, a lot of wells are put on production and that acid water is removed right along with the production. They do not make any attempt to clear up that acid water before they put it on production.

Q. When spent acid is removed from a well, do you know what operations are performed to get it out of the well? A. It is usually swabbed.

Q. Will you explain how that acid is gotten out of

the well by swabbing? By that, I mean how is the spent acid gotten out of the well by swabbing? A. After the operator determines the shut-in period, and after he leaves it shut the length of time that he had decided upon, I presume you know what a tubing swab is; well, they merely swab that tubing down until they have swabbed sufficient fluid to carry out the spent acid. In some cases they, of course—most cases, the spent acid is noticeable when it comes back, and after that spent acid has been swabbed back, they then proceed to put the well on production.

Q. Then you are familiar with the methods of removing spent acid after acidizing? A. Surely.

CROSS EXAMINATION

When I am treating a well for the Halliburton Oil Well Cementing Company, right after I have put the acid in, that is, after I have pumped the acid into the well, I then pump the flushing oil in the well right behind the acid. After that, I am finished with the treatment.

RE-DIRECT EXAMINATION

By Mr. Conner:

Q. You stated that after you have finished putting the oil in on top of the acid and place the acid, that you are then through with the acidization of that well, is that your statement? A. That is correct.

Q. What will keep the oil in the tubing and in the casing? Are there any closures made by way of valves? A. There is always a tubing gate on the tubing.

Q. Is that tubing gate closed? A. The tubing gate is closed until we have broken off our connections, then the operator, it is up to him whether he wants to go ahead, let that come back immediately, or whether he wants to let it remain in that well for some length of time. It is immaterial.

Q. Is there also a tubing gate on the casing—would

it not be necessary to have the tubing gate on the casing closed to keep the acid and oil in place? A. That is right.

Q. Then, when you break your connections from the tank and tubing to leave, before you can do that, the tubing gate on the tubing must be closed first, must it not? A. Yes, sir.

Q. Now, it is necessary, is it not, to close that tubing gate and close the casing gate valve in order to keep the acid in position? A. That gate is merely closed after we finished treatment, for us to break away connections.

Q. I am not asking who closes it, but I ask you, is it not a fact that it is necessary to have the casing shut in and the tubing shut in after you have put that acid and oil in the well? It is necessary to have those two valves closed in order to keep the acid and oil in its proper place and effect acidization in the well? A. That is very true, but after the acid is pumped in there, there are some formations that it is complete the minute that acid is pumped in the formation. It is the general practice in lots of places that the operators remove that as soon as it is pumped in. There is no shut-in period.

Q. When there is a shut-in period, is it not then necessary to keep those valves, namely, on the tubing and casing, closed? A. That is right.

Q. When you are pumping oil into the well on top of the acid, there is this connection between your pump and the source of oil and the tubing, of some sort, is that not right? A. That is right.

Q. Now, you have put in sufficient oil, as you have computed it to be necessary, and you are to break your connections, go on home and eat dinner, who, as a matter of fact, unhooks your connection from the well? A. Usually my employees, those under my supervision, sometimes the employees of the operator.

Q. Then, who closes the valve on the tubing before the connection is broken? A. That is either one of the operator's employees or myself and crew.

Q. Then, in some instances it could be yourself or one

of your helpers who does close the valve on top of the tubing? A. It is possible, but we are working under the instructions of that operator.

Q. You said, though, did you not, that sometimes you did that? A. That is right.

Q. Is that also true with the valve on the casing? A. It is.

Q. It is already closed, is it? A. It is already closed.

Q. In connection with the stage treatment, for instance, a two-stage treatment, is the acid left in the well any length of time, when the acid is put in in the first stage? A. Well, that all depends upon the operator, whether he wants to let it stay or swab it right out.

Q. Assuming you are treating a well in two stages, and doing it all in one day, when the first batch of acid constituting the first stage is put in the well, do you withdraw that first batch? A. In some cases the operator does, in some cases he does not.

Q. In the cases where the operator does not withdraw it, who does withdraw it? A. It is usually the operator or one of his men there. On stage treatments, usually the first stage is considered, you know, kind of immaterial as to leaving it stand and it is usually swabbed right back out.

Q. Now does the operator know it should be swabbed back out if you don't tell him to? A. Well, now, that is the operator's business. Here is the thing, nearly every operator, especially any operator that has any production at all, has a man that he depends on for that purpose.

Q. Well, acidizing is your business, is it not? A. That is right.

Q. Isn't that two-stage acidization of the well one of the services you offer? A. That is right.

Q. One that you recommend under certain conditions? A. Well, of course we could recommend it, very true.

Q. You do give two-stage treatments? A. That is right.

Mr. Owen: Then we will put the large bunch, beginning with 6581 in as Exhibit 17, twelve tickets.

And the four tickets which are not a part of the large bunch will be offered as Exhibit 18, four tickets.

(The tickets referred to were thereupon marked Plaintiff's Exhibits 17 and 18, respectively.)

The Court: That is right. And the objection goes to PX-18 and I overrule it and admit it.

PAUL G. SHELLEY,

a witness called by plaintiff, testified as follows by deposition:

DIRECT EXAMINATION

I live at Midland, Michigan, and have been in the employ of The Dow Chemical Company as a research chemist since October, 1936. My work has to do with oil production in general, but especially with acidizing development, developing techniques, and methods and solutions used in acidizing wells. The majority of it has been laboratory work, but I would say at least 25 per cent of it has been field work.

I am familiar with the methods of acidizing oil wells to increase production by using hydrochloric acid and I have observed acid treatments given to oil wells located in most of the Michigan oil fields, Greendale, Porter, Allegan, West Branch, over west of Grand Rapids, and also down in Clay

County, Illinois, and in Louisiana. I have treated a dozen or two or more wells with acid to increase their production.

I have witnessed the Halliburton Oil Well Cementing Company acid treat wells owned by the Weber Oil Company, the Stella Wilcox Well No. 3 treated on August 5, 1938, the Robert Zahn Well No. 2 treated on August 19, 1938, and the Crawford Well No. 5 treated on September 10, 1938. These wells were located in Ogemaw County, Michigan, and were all given acid treatments by the Halliburton Oil Well Cementing Company. I was present and observed the treatment of all of these wells.

With respect to the Wilcox well which was treated on August 5, 1938, I went over to the well about seven o'clock in the morning. The driller, Stanley Hamilton, was there. We swabbed the well a few times. I found out at that time they had a packer set, a pipe which was about at the pay—about 2600 feet deep, I believe. About 8:30, I guess it was, the Halliburton men came to the well. The treater, Carl Nicholas, came in a coupe with the Halliburton name on it, then there was an acid truck and trailer, carrying 2000 gallons of acid, also a Halliburton piece of equipment that came at the same time, driven by a driver whose name I believe was Harold Aspin. Nicholas asked, as soon as he got there, to see if the well was swabbed dry; he checked the annular space, opened up the casing head, poured a little water in it, found it was full, plugged it up and made the connection. Then they made connections from this part of the pump to the tubing head, connected up the cable from the truck to the tubing head. The first thing they pumped about 10 gallons of some stuff that they called blanket into the tubing and then immediately followed that with acid, and continued to pump acid until they had pumped the entire 2000 gallons into the well. The first part of the acid, about 1500 gallons, went in on vacuum; the last 500 pressure started to build up and they had about 600 pounds pressure on the tubing. Then when the acid was all in, they switched to oil and pumped I believe 25 barrels of oil in that well as a flush. That went in at 600 or 700 pounds. When that was

done the treatment was over and Mr. Nicholas advised that they leave it shut in for an hour or so. The Mr. Nicholas I refer to was a Halliburton treater and he was in charge of the job. Mr. Nicholas advised either J. E. or W. L. Steelman that the well be shut in for a while. I was present and heard the conversation. I don't remember exactly what Mr. Nicholas said, but that is what he advised and that is what they did. During the treatment of this well, I was present the entire time; also present were J. E. Steelman, W. L. Steelman, Stanley Hamilton, and the two Halliburton men, Nicholas and Aspin.

With respect to the Robert Zahn well which was treated by Halliburton on August 19, 1938, I did not witness the entire treatment of that well. As I remember it was a sort of three-stage affair and I saw only the first stages of it. I was present when the Halliburton men put acid into the well. I went over to the well in the morning. Ralph McCannon was a driller on that well. Pretty soon the Halliburton boys came to the well. Nicholas came in a Halliburton coupe; a couple of other fellows I had never seen before came in the Halliburton coupe. I later found out their names were Anthony and Swain. The acid came in a Halliburton truck and trailer, 2000-gallon capacity outfit. It was driven, I believe, by a fellow by the name of Campbell. They checked the casing, annular space again, put a gauge on it, hooked their cable up from the truck to the well head, and pumped about three gallons of this blanket in first and immediately followed that with 250 gallons of acid. Then they followed that with oil. I believe they pumped about 11 barrels of oil on top of that. They got up a little pressure getting the last of that oil in. Then they recommended that the well be shut in for over the noon hour is what it amounted to. About one o'clock they came back and directed McCannon and me to start swabbing the well, which we did, and swabbed it down to about as dry as we could get it, hooked the pipe back on to it, pumped in about 500 gallons of acid, and flushed the tubing again with oil to the tune of about 12 or 14 barrels. Just about that stage of

the game is when I left. I stayed there possibly for a little bit of the swabbing. A swab is a little rod with rubber cups on it you run down the well. You run it down on a cable, goes through the fluid and when you pull it back out it has valves in it which close and this raises the column of fluid in the well. It is about the same as either producing a well or getting the fluid out of it. During the treatment of this well, W. L. Steelman was present most of the time and J. E. Steelman was present off and on, and that was also true with respect to the Wilcox well. There were conversations between the Halliburton representatives and the Weber Oil Company representatives which had to do with putting the well back on production. Mr. Nicholas made about the same suggestion as before, namely, that the well be left for a period of time, about an hour, as I recall, before they started swabbing again. He made that statement either to the driller or W. L. Steelman, I don't remember which, but I do recall that such a statement was made by Nicholas.

I was present during the entire time that the Weber Oil Company's Crawford Well No. 5 was being treated by Halliburton on September 10, 1938, and I observed the treatment. I went over to the well about seven or seven-thirty in the morning, and Ralph McCannon, the driller that had been on the Zahn well, was over there, and also a fellow helping him, and shortly after that W. L. Steelman came to the well. We changed the casing head and hooked the thing up so it was ready to be treated. Shortly after that Nicholas came to the well with his Halliburton coupe. Then he and Mr. Steelman left the well and went back to try to get the truck and trailer out of the mud, which took them until about ten-thirty. Finally they got it over there and they hooked the pump up to the well head, and hooked a section of the pump to a tank of oil sitting there about 100 feet away from the well, and started to pump oil into the tubing with the casing open. This well didn't have a packer. They continued to pump oil until the well was full, as evidenced by oil coming out of the casing head. That took about 41

barrels of oil. Then they mixed their blanket, or else it was already mixed—I don't remember specifically on this well —and pumped about 10 gallons of blanket into the tubing. They followed that with 450 gallons of acid and then they shut down for about five minutes, according to Nicholas, to let the blanket drain out and get down to the bottom of the well; then pumped another 10 gallons of acid to fill up the space in the well over the pay formation, all this time circulating oil back to the casing head. I forgot to mention they had a line from the casing head back to the oil storage tank. They continued to pump acid at a very slow rate with about 200 or 300 pounds on the tubing, with about 700 or 800 pounds on the casing, until they had pumped the entire 2000 gallons of acid into the well. Then they went back on oil, flushed the tubing with about 12 or 14 barrels of oil on top of the acid. At the end of that pumping, the pressure on the tubing and casing was equalized to about 700 pounds. The 450 gallons of acid was of such volume that it was calculated to just fill the tubing. I don't know exactly what the depth of the tubing was, but it was somewhere around 1600 feet, and that is close to the volume of acid it takes to fill the tubing at that depth. At the conclusion of this well treatment, Mr. Nicholas said he would leave the well set there a couple of hours and then put it back onto production. This statement was made to Mr. Wesley Steelman or Mr. McCannon. I cannot remember which, but I was present when Mr. Nicholas made this statement.

In the treatment of all three of these wells, the blanket was introduced into the bottom of the well. It was put into the tubing ahead of everything else and was pumped to the bottom. The blanket was put into the well in each instance before the acid, and that is true of all three treatments.

While present observing these three treatments, I noticed that Halliburton had an electrical cable hooked up in each instance. I don't believe I mentioned that on the Crawford well, but during the pumping of the 450 gallons of acid I was talking about, they got the cable out, and strung it to the tank and connected it to the tubing head. Such a

connection was made at some time or another during my stay at all three of these well treatments. This connection consisted of about one-half inch copper cable with rubber insulation. The cable connected the tubing head to the tank, so far as I could see, and it was also connected to something on the tank. That is, one end of the cable was connected to the tank, and the other end to the tubing head. Of the men I have mentioned, Nicholas, Swain and Campbell were Halliburton representatives, while J. E. Steelman, W. L. Steelman and McCannon worked for the Weber Oil Company. I am able to remember the exact details of the treatments of these three wells because just as soon as I came away from a treatment I wrote it up while it was fresh in my mind, and I have had access to those notes to keep my memory fresh.

The way in which I happened to be present during the treatment of these wells, the Wilcox, Zahn and Crawford, was that Mr. Conner asked me to go to these jobs and see if I could find out what was going on, to watch the treatments and get samples of the materials put into the wells if possible. Apparently through Mr. Conner's arrangement, I made contact with J. E. Steelman, the Weber superintendent in that district, and it was all right with him so I went out to the wells. I was present during the treatments of these wells for the purpose of observing the treatments and obtaining samples.

I obtained samples of acid used in treating the Crawford well on September 10, 1938. Before Halliburton started to pump any acid into this well Mr. Steelman brought a couple of one-gallon stoneware jugs over to the well and asked Nicholas if he would fill them up for his father, J. E. Steelman. The jugs sat around there for a while. During the period when they were circulating their tanks to mix some of the ingredients they put into the acid, they opened up a little auxiliary suction line on the pump and drained the acid into the jugs. Along towards the latter part of the afternoon J. E. Steelman came over to the well, picked up the jugs, and took them away. I saw

J. E. Steelman obtain that sample of acid. I saw the whole thing; everything that happened. Later I obtained possession of the acid sample. After the treatment was over, I went to J. E. Steelman's house where he had taken the jugs of acid. There I met E. C. Hardy, a Dowell engineer, and in Hardy's presence Mr. Steelman turned the jugs of acid over to me. I split the sample of acid into four samples which I put into half-gallon glass-stoppered bottles and proceeded to seal the samples and to label them as to what they were and where they came from. I wrote the labels out myself and they bore my signature as having witnessed the taking of the sample. I think Mr. J. E. Steelman also signed the label as having taken the sample and probably W. L. Steelman as having witnessed that, but I cannot be too sure. The labels stated that the contents were samples of hydrochloric acid which were obtained from the Halliburton trucks on the treatment of the Crawford Well No. 5, treated September 10, 1938, and that the contents were samples of the materials put into the well by Halliburton. The containers into which these acid samples were put were two one-gallon stoneware jugs, and when the samples later that day were turned over to me by J. E. Steelman, they were in exactly the same containers as when he took them, namely, one-gallon stoneware jugs. After receiving these samples and putting them in four half-gallon glass-stoppered bottles and labeling them, Mr. Hardy and I brought them to Midland, Michigan, and got in touch with Mrs. Rose Gilroy of Mr. Campbell's office. She came to the office and opened up the vault and locked the samples in it. That was done on the same day, September 10, 1938.

When the Weber Oil Company's Zahn Well was treated by Halliburton on August 19, 1938, I also obtained samples of the acid used by Halliburton in treating this well. At J. E. Steelman's house we again met Mr. Hardy and I proceeded to transfer the acid into half-gallon glass-stoppered bottles and sealed and labeled them. I labeled these samples as being hydrochloric acid obtained from the truck tank of the Halliburton acidizing truck on August 19, 1938,

during the treatment of the Robert Zahn Well No. 2. I signed that label myself, I think, as having taken the sample. W. L. Steelman was there at the time we got the sample and he witnessed it. This acid sample which was obtained when the Zahn well was treated was in my possession all the time. I requested the sample, saw it taken, and had it in my possession all the time.

When the Weber Oil Company's Wilcox well was treated by Halliburton Oil Well Cementing Company on August 5, 1938, we obtained samples of the acid used by Halliburton in treating this well. In this instance J. E. Steelman brought his two one-gallon stoneware jugs over to the well and asked Nicholas if he would fill them up. They were filled right out of the Halliburton tank on the truck. That was before they had ever pumped any acid into the well. This was in the morning. I can't remember who took the samples away, but they were taken to J. E. Steelman's house and transferred to glass bottles, sealed and labeled, the same as the others. In both cases, I think it was the Halliburton driver who took the acid sample out of the Halliburton tank. Either W. L. or J. E. Steelman, I don't remember which one, transferred the acid samples from the well site over to J. E. Steelman's house, where I then put the samples into bottles and labeled them as hydrochloric acid obtained from the Halliburton truck on August 5, 1938, and being the same as the material furnished by Halliburton and put into the Weber Oil Company's Wilcox well. I signed the labels and one or the other of the Messrs. Steelman also signed them.

The samples obtained on August 5, Mr. Hardy and I brought to the office of The Dow Chemical Company at Midland, Michigan, and turned over to Mrs. Rose Gilroy, who locked them in the office vault in our presence. In each instance, the bottles used were brand new bottles which we had procured from the stock room in the Dow Plant. They were new bottles and absolutely clean. I know that the stoneware jugs in which the samples were obtained at the well were clean because I washed them out every time I used them.

With respect to the samples obtained on August 5, 1938, when the Halliburton Oil Well Cementing Company treated the Weber Oil Company's Stella Wilcox No. 3 well, I transported those samples to Midland, Michigan, on that date and I believe I turned them over to Mrs. Rose Gilroy. Likewise, when the Weber Oil Company's Crawford Well was treated on September 10, 1938, by Halliburton Oil Well Cementing Company, I transferred those samples to Midland, Michigan, on that date and likewise turned them over to Mrs. Rose Gilroy. On August 19, 1938, when the Halliburton Oil Well Cementing Company treated the Weber Oil Company's Robert Zahn well and I obtained samples of the acid used, I transferred these samples to Midland, Michigan, and that night locked them in Building 280 at the Dow Plant, and on August 29, 1938, I deposited these samples in the vault of The Dow Chemical Company's office at Midland, Michigan. At that time I think I turned them over to Mrs. Rose Gilroy. It was in the daytime and Mr. Conner and I took them over to the vault. When samples were obtained from the Zahn, Wilcox and Crawford wells, I saw that the samples were deposited in the main offices of The Dow Chemical Company at Midland, Michigan.

I had something to do with samples of materials which were marked Nos. 14 and 20. These were samples that were brought to the office in glass jars. I do not know exactly when these samples were brought in, but one set had a date on the label of August 18, 1938, and the other set bore on the label the date of December 6, 1938, I believe it was. They were samples of hydrochloric acid, which, according to the labels, had been obtained from the north and south storage tanks of the Halliburton Oil Well Cementing Company's station at Mt. Pleasant, Michigan. These labels were signed by Mr. Day and Mr. Forsman. There was a total of four samples, two marked August 18, 1938, and two marked December 6, 1938, coming from both the north and south tanks on each of these days. I transferred these samples into glass bottles so that they could be sealed, and relabeled them and signed the labels as having made the

transfer. I do not recall anything about who may have brought the samples to the Midland office. I simply relabeled them. The label I applied to these bottles carried my signature. The data which I put on these labels I obtained from a sticker on the jar in which the sample was originally contained and which identified the sample. So far as I know, Mr. Conner gave me those samples for the purpose of rebottling and relabeling.

CROSS EXAMINATION

When the Wilcox and Zahn wells were treated, a packer was employed. I know that because it was common knowledge that there was a packer on these wells. The packer was on the tubing and the acid went below the packer, so that if the packer held in these Wilcox and Zahn wells, the acid would not come in contact with the casing pipe. The first 1500 gallons of acid went in pretty fast, but the last 500 gallons went in slowly. I would say that the acid was in contact with the tubing at least an hour. In the only treatments I saw on the Zahn well, the acid would not have been in contact with the tubing over an hour or two.

Two sets of the acid samples obtained came directly from the Halliburton truck tanks. The other set of acid samples was taken when they were circulating. They had used Klersol, and had circulated the tank for at least five minutes and were in the process of mixing Klersol into the truck or trailer tank. Somebody said this would be a good time to get the sample. They opened up the drain. This was on the Crawford well.

By Mr. Babcock:

Q. I want to know whether the sample would be truly representative of what Halliburton hauled out to the well or whether it would be contaminated by, say, some of the oils, mercaptans, or other things in the well? A. There is no question of that in my eyes. Two of the samples came out of the tank, the other acid sample came out of circulation

from the bottom of the tank. There would be no possibility for any contamination of any sort.

We used the same stoneware jugs each time. The first time we used them they were brand new, and as we finished transferring the acid from them we washed them out good, stoppered them, and put them away until we got ready to use them again. Whether they were rinsed again I do not know. These stoneware jugs had never been used for anything else in their lives from the time they were new until they got into this deal. I do not know whether the samples of acid I took were samples of inhibited acid or not. I had nothing to do with the testing of this acid.

In the Wilcox, Zahn and Crawford wells, oil was being produced from the Dundee formation in two of these wells, and I am not sure whether it was being produced from the Dundee or Traverse in the other. I believe it was from the Dundee formation in all of them. The Traverse formation is also limestone. Previous to the three well treatments to which I refer, Halliburton Oil Well Cementing Company had made one other well treatment for the Weber Oil Company that I know of.

The Messrs. Steelman that I refer to are father and son, and I would definitely say that they were oil men. The Weber Oil Company's driller probably knew something about oil. I do not think that Mr. Nicholas had to instruct the Weber Oil Company's representatives with respect to treating these wells. I think Mr. Nicholas offered information as a suggestion which the Weber men were perfectly willing to follow. Even though they are oil men, it is sort of general practice for most oil men, especially smaller outfits, to pretty nearly accept the recommendations of the acidizing or service company as to what they are going to do to a particular well. My impression is that they feel like the service companies know more about treating their well than they do, from the service end of it.

Q. How do you regard the statements of Nicholas as to how long the well should remain shut in after the acid was introduced, as to what he thought to be the best practice? A. Well, it was a little more than that, although I

feel, absolutely, if either of the Messrs. Steelman had had any instructions from Weber Oil Company, they probably would have followed those in preference to Nicholas' suggestions. Nicholas made the statements in such a way it appeared he intended the well to be shut in as he said.

This conversation between Nicholas and the Weber Oil Company's representatives took place at the Zahn well, between the stages of treating it. It was noon and they all left and went to lunch during the shut-in period. The second time Mr. Nicholas suggested that the Zahn well be shut in, I was there and it was during the second shut-down period of the Zahn well treatment. I stayed there and just started to swab the well when Mr. Steelman came and said, "Let's go." On the Crawford well the treatment was all over and they left. I left too. The well was necessarily shut down because it would take them longer than that to run the rods into the well and get the well to produce. They didn't start to do that immediately.

I have no knowledge of what happened on any of these wells after the acid was placed into the well and after Halliburton left except in the case of between the stages of the treatments on the Zahn well. I don't know what happened on the other wells. On the stage treatment of the Zahn well, the acid was forced into the formation, withdrawn, and then a new batch of acid was forced in and withdrawn. The spent acid was removed at the end of the first stage by swabbing the well for about an hour until we couldn't get any more fluid out of the well. I do not know how much spent acid we got out of the well. Mr. McCannon of the Weber Oil Company and I did the swabbing.

When the Weber Oil Company's Stella Wilcox well was treated August 5, 1938, by the Halliburton Oil Well Cementing Company, the acid in the tank was not circulated or stirred up, and we got the sample of acid out of the truck tank in the morning, before Halliburton had pumped any acid into the well.

By Mr. Babcock:

Q. So, in your opinion, there couldn't have been any

contamination, no mixture of acid? A. No, not in that case, or any of them, but specifically it wasn't possible for anything to be in that jug that wasn't in the tank. There may have been oil in the tank they had gotten somewhere else—I don't know anything about that, but so far as the acid that went into the well it was the acid that Halliburton brought to the well.

Q. Did you look into the tank? A. I think so, yes.

Q. But you don't remember whether there was any oil on the surface of the acid or on the walls of the tank? A. Well, I just can't be absolutely sure about it. I just didn't have that in mind at the time. There probably was skim oil on it. You can hardly find a tank that there isn't skim oil on it.

Q. Is it customary in these acidizing jobs to circulate oil through the tanks sometimes? A. Well, sometimes it is customary to get oil in the tank, sometimes in the pumps. You pump oil to flush your pump out after you finish, flush the tubing, and then flush the pump. You drain it but if you are trying to establish the fact there is the possibility there may have been oil in the tank, the answer to that question is yes. It is impossible to keep all the oil out unless you bring the acid all in glass jugs. There was nothing taken from this treatment except the material that got into the jug.

Q. On the Crawford well was the same pump and same tubing used to circulate the acid that was used in the treatment to pump the oil? A. Same pump.

Q. Same tubing too? Part of the same tubing? A. No, they usually hook another hose on the side of the tank, circulate it. They make pipe connections from the well.

When the Weber Oil Company's Zahn well was treated by Halliburton Oil Well Cementing Company on August 19, 1938, the acid samples were obtained in the interval between the two stages of treating this well. The acid sample was given to me by one of the Halliburton men, upon request, who took it from the manhole of the Halliburton truck tank. On this well we did not swab any oil or acid back into the

Halliburton truck tank. We did not circulate the acid back into the Halliburton tanks. We didn't circulate anything back into the Halliburton tanks. The procedure on the Zahn well was to pump 3 gallons of blanket into the well, which was followed by 250 gallons of acid, then followed by about 10 or 12 barrels of oil. The well was then shut down for a while after which it was swabbed, but we swabbed back into the Weber Oil Company's lease tank. It was not a matter of circulation, it was a matter of cleaning the well out to get the spent acid back by swabbing it out. The spent acid went into the Weber lease tank. Then, on the second stage of the treatment of this well, more blanket was put in, about 5 gallons of blanket and 500 gallons of new acid and we did the same thing over again. The oil that followed the acid went back into the Weber lease tank. (Witness refers to notes.) On the second stage of this treatment we did exactly the same thing. A sample of the acid was taken between the two stages. It was then taken out of the Halliburton truck tank. Never had there been any opportunity for anything to get into the Halliburton truck tank at all. In other words, the material in the Halliburton truck tank didn't have any opportunity to be contaminated with anything that had been in the pump because nothing circulated from the pump back into the Halliburton truck tank. This Zahn well was the instance where I asked the Halliburton man to get the acid sample out of the Halliburton tank.

With respect to the acid sample obtained when Halliburton treated the Weber Oil Company's Crawford well on September 10, 1938, the sample was taken before any acid was pumped and during a period of circulation. Whether it was taken before or after pumping oil I would not know. (Witness refers to notes.) The acid sample from the Crawford well was taken after the oil had been pumped. This sample was taken from the pump after we had finished pumping oil and had circulated the tank. A blanket was also used in this treatment. The blanket was put into the well and then followed with acid. There was no packer

in this Crawford well; the well hole was filled with oil prior to the treatment, and we forced the oil into the well to place the blanket into position and circulated the oil back into the lease tank by means of the Halliburton pump. Then, with the Halliburton pump, we pumped oil from the lease tank into the well tubing until the casing, tubing and all of the well was full of oil. Then, I think it was that we started mixing up the acid, but I cannot be too sure of that until I check. (Witness refers to notes.) Yes, we finished pumping oil and then mixed chemicals and circulated them with the Halliburton pump. This circulation consisted of taking suction out of the bottom of the Halliburton tank and running the acid through the Halliburton pump and back into the Halliburton tank it came from.

RE-DIRECT EXAMINATION

As to how long the acid was in contact with the tubing during the treatment of the Crawford well, four hours would be within 20 per cent right. I would absolutely say, with respect to all the acid samples I obtained, that there is no doubt but what the samples were absolutely representative of the material that went into the oil wells. Had I not taken the samples of acid coming from the Halliburton tanks, that same acid would have been put into the oil wells.

RE-CROSS EXAMINATION

By Mr. Babcock:

Q. In the Crawford well, it's a cinch, as far as I can see, what went into the well from the Halliburton tank wasn't only some acid but also some oil that came out of the well, isn't that true? A. Well, that's possibly true, yes. There might have been a little oil left in the pump.

Q. I am only speaking of a little, but it's a cinch some oil that was circulated got into there? A. Yes, you open up the drain, there is some oil that sticks in the pump, a little oil held up over the valves. It would be silly to maintain the acid was absolutely completely oil-free.

JOSEPH E. STEELMAN,

a witness, called by plaintiff, testified as follows by deposition:

DIRECT EXAMINATION

I live at West Branch, Michigan, am an oil field superintendent for the Weber Oil Company of Bay City, Michigan, and have worked for them since July 30, 1933. My duties include superintending the drilling and producing of crude oil for the Weber Oil Company, and I have charge of the Weber Oil Company's wells in Ogemaw County, Michigan, and elsewhere.

It is the practice of the Weber Oil Company to have its wells treated with acid and this work has been done by Dowell Incorporated and Halliburton Oil Well Cementing Company. The Weber Oil Company owns and operates in Ogemaw County, Michigan, wells known as the Wilcox No. 3, Zahn No. 2 and the Crawford No. 5. My records show that Halliburton Oil Well Cementing Company acid treated the Stella Wilcox Well No. 3 on August 2 and August 5, 1938, the Robert Zahn Well No. 2 on August 19, 1938, and the Crawford Well No. 5 on September 10, 1938.

On August 5, when the Stella Wilcox Well was acid treated by Halliburton, Paul Shelley received from me samples of the acid used in treating that well. The acid sample was taken out of the tank by one of the Halliburton men, I believe, and handed to him. I took the samples to my garage so that they wouldn't be broken or destroyed at the well and gave them to Paul Shelley. He took the samples from my garage, which was not probably more than an eighth of a mile from the well, and it was there at my garage that I gave the samples to Shelley.

Again, when Halliburton treated the Zahn well on August 19, we obtained samples of the acid used. I took the sample home to take care of it until Shelley came and got it. In each instance when I took the sample from the well

to my house, the sample did not leave my possession until I gave it to Mr. Shelley. From the time that I obtained the samples at the well and took them to my house and turned them over to Shelley, I did not add anything to them and they did not leave my possession.

I have in my possession records which will show the production of the Wilcox well before it was acidized on August 5, and also its production after it was acidized. I will give the production figures in feet and inches and also the rate of barrels to the foot, and you can do the actual figuring. On July 28 the Stella Wilcox made 1 foot 1 inch of oil in a 100-barrel tank that we estimate makes 10 barrels to the foot. On July 29 it made 1 foot even in a 100-barrel tank. On July 30 it made 1 foot. On July 31 it made 1 foot. August 1 there was no production for the reason that we had to run tubing to use in acidizing the well. On August 2 we swabbed a foot of oil, that is before you start putting the acid in. On August 3 the well made 5 feet 1½ inches in a 100-barrel tank. On August 4 it made 4 feet. On August 5 it made 3 feet 10 inches. Of course, as all acidizing men know, that figure on August 3 contained a lot of acid in there and water. August 6 production shows 10 feet 6 inches in a 100-barrel tank. August 7 shows 5 feet 8 inches. There is a blur on my record for August 8, but it looks like the well made 2 feet 3 inches. On August 9 it made 4 feet 1 inch. On August 10 all the production shows here is 2 inches in a 500-barrel tank. Now, get the difference because that 2 inches here is in a 500-barrel tank. August 11 it doesn't show any production. That is the end of the production records for that well because on August 12 they pulled the rigging down. The production records show that as a result of acid treating this well the production was increased probably by two-thirds for at least thirty days.

I have similar records showing the production of the Zahn Well No. 2, which was acidized by Halliburton on August 19, 1938. These records begin on August 6, on which date the well made 3 inches in a 100-barrel tank. On

August 5 the well made 5 inches. On August 6 it made 6 inches. August 9, 6 inches. On August 10, it made 2 inches. August 11 it made 5 inches. August 12 it made 2 inches. August 13, 4 inches. August 14, 4½ inches. August 15 it made 4 inches, and August 16 the same amount. That is the end of that period of production because we had taken down the well rigging. I have production records here that show the well was treated on August 19, 1938. The record for August 20 doesn't show any production at all. The record shows that for August 21 the production was 3 feet 2 inches, which also includes part of 1 foot 11 inches of oil put down into the well when acidizing it. The next production record I have for this well is for August 23, showing the well produced 3 feet 11 inches in a 100-barrel tank. On August 24 the production is 2 feet. There was no production on August 26 because we were pulling the tubing and taking the packer off and rearranging the pumping equipment. The next production record I have for this well is on August 15, 1938. I have no production records for this well for September as we were constructing a new tower on that well at that time and we had quite a delay. I have production records on the Zahn well which show its production after it was put on the pump. These records start with October 15, 1938, and show that on that date the well made 10 inches in a 250-barrel tank. On October 16 it made 7 inches in the same tank. October 18 it made 4 inches. October 19, 5 inches. October 20 it made 3 inches. October 23, 2 inches. October 25, 1 inch. October 26, 4 inches. October 27, 3 inches. October 28, 5 inches. October 29, 4 inches. October 30, 3 inches.

I also have production records on the Crawford Well No. 5 which show its production before it was acidized on September 10, 1938. On September 1 this well made 10 inches of oil in a 100-barrel tank. On September 2 it made 10 inches. September 3, 11 inches. September 5 it made 1 foot 5. September 6, 8 inches. September 7, 8 inches. September 8, 3 inches; we were running tubing that day. September 10 the well was acidized and we used about 5

feet of oil from a 100-barrel tank. On September 11 the well made 4 feet 1½ inches in a 500-barrel tank. September 12 the well made 3 feet in a 500-barrel tank. September 13 it made 2 feet 6 inches. September 14 it made 1 foot 9 inches. September 15, 2 feet 2 inches. The records then show the well was closed down for want of tank room.

I was present at intervals during the treatment by Halliburton of these three wells. I was at the well part of the time, what time I could spare from my daily routine duties. To the best of my memory, I was present at the conclusion of the treatments. I have many other duties in this field and on the days these wells were treated I divided my time. But I was present at least part of the time. I don't recall any conversations at the conclusion of these treatments between myself and the Halliburton men who were treating the well which had anything to do with putting this well back onto production. I don't recall hearing anything out of the ordinary whatsoever, maybe just some suggestion about how to fix the line or something. At this time I don't recall any suggestions or discussions with the Halliburton men about what next to do to the well, about bringing it back to production.

CROSS EXAMINATION

As to the kind of packer we used, it was just a rubber expanded Larkin wall packer. Halliburton did not do anything to protect our tubing from corrosion, so far as I know. If they did, I did not know what it was. I don't know how they could do anything to protect the tubing. To my knowledge, they never any of them do. Halliburton has not acidized any wells for the Weber Oil Company other than these three. I recall how I happened to select Halliburton to acidize these three wells. It was at the request of Dowell Incorporated. Also, we were interested to know if Halliburton's treatment would be any better. We are always looking for improvements.

WILLIAM S. DAY,

a witness called by plaintiff, testified as follows, by deposition:

DIRECT EXAMINATION

My address is Mt. Pleasant, Michigan, Route No. 4. I am district manager for Dowell Incorporated, whose business is that of acidizing oil wells. My territory covers Michigan, part of Ohio and Canada.

The Halliburton Oil Well Cementing Company is located in Mt. Pleasant, Michigan, and their business is also that of acidizing oil wells. That company did have two wooden storage tanks at Mt. Pleasant. They have one steel storage tank now. I saw the wooden storage tanks of Halliburton's up until about six or eight months ago. I have seen these tanks on several occasions; they were located on North Franklin Street and contained hydrochloric acid. I know this because on two different occasions I got samples out of them. These tanks set right alongside of each other, one north, and one south, which I refer to as the north and south tanks.

The first occasion I obtained samples from these tanks was on August 18, 1938. I took the samples to my office, labeled them, locked them up, and brought them to the office of the Dow Chemical Company at Midland, Michigan, where I gave them to Mr. Conner. I labeled the acid as being taken out of Halliburton's tank on that date and I had the date on the sticker. I also designated whether the sample came from the north or south tank to identify the tank to which the sticker referred. I signed the labels.

I obtained other samples from both these tanks on December 6, 1938. I disposed of these samples in the same manner as the first. These samples contained labels the same as the first samples and I signed the labels.

In each instance the sample of acid I obtained from each tank was about two or three quarts. Whatever sam-

ples I took from these tanks I delivered to Mr. Conner at Midland, Michigan. When I obtained these samples Warner Forsman, bookkeeper in our station office at Mt. Pleasant, was with me each time, and he was with me each time I delivered the samples to Mr. Conner. When I obtained these samples on August 18, 1938, and December 6, 1938, I got the samples in a new clean glass jug.

CROSS EXAMINATION

These wooden tanks had no oil around them or anything in them besides acid. They were just hydrochloric storage tanks of 250 barrel capacity. When we (Dowell) come back from the well and have not used all of the acid in our truck tank, we never pump it back into our storage tank. My recollection is that these Halliburton tanks had no oil around or in them at any time I took the samples.

I got the samples through the manhole cover in the top. No Halliburton men were there, if there had been I would have asked them for the samples.

RE-DIRECT EXAMINATION

I recognize the top picture of PX-168 as being the Halliburton storage tanks located at Mt. Pleasant, Michigan. The storage tanks depicted in that picture are the same ones from which I obtained samples on two different occasions.

WARNER FORSMAN,

a witness called by plaintiff, testified as follows, by deposition:

DIRECT EXAMINATION

I am district office manager for Dowell Incorporated at Mt. Pleasant, Michigan. I have been employed by Dowell for approximately four years. Dowell is engaged in oil well acidizing and cementing.

The Halliburton Oil Well Cementing Company have an office at Mt. Pleasant, Michigan, and are also engaged in the business of acidizing wells. On numerous occasions I have seen the Halliburton storage tanks located on North Franklin Street. I recognize the top photograph in PX-168 as being a picture of the Halliburton acid storage tanks I refer to. These tanks contain hydrochloric acid. I know this because they are similar to Dowell's tanks which are used for the same purpose. I have seen Halliburton's trucks load acid out of these tanks and we have also obtained samples from these tanks. There are two tanks. I would identify them as north and south, as one tank lies directly north of the other. I have obtained samples from both tanks on two occasions. The first was on August 18, 1938, the second on December 6, 1938. On each occasion I obtained approximately three-quarters of a gallon of acid from both the north and south tanks.

When the samples were taken, they were immediately identified as to which tank they were obtained from and they were delivered to The Dow Chemical Company at Midland, Michigan, to Don Conner. The samples were identified by labeling each sample with respect to the location of the tank. We marked the first sample we obtained in August N-14 and S-14. They were labeled over here and we signed our names to the labels indicating the tank from which each sample was obtained.

On August 18, 1938, I got a sample from both the north and south tank and these samples were put in separate con-

tainers. The labels showed the dates on which the samples were obtained and bore the signatures of W. S. Day and Warner Forsman. Similarly in obtaining the samples on December 6, 1938, each bottle was labeled in a like manner and bore my signature and that of Day. After obtaining these samples on both occasions they were brought to Dowell's office, and delivered to The Dow Chemical Company's office within ten hours from the time they were obtained and delivered to Don Conner.

CROSS EXAMINATION

Q. How did you obtain these samples? A. They were obtained in a clean glass jar.

Q. I mean did you get them out of the top of the tank? A. Yes.

Q. Who climbed up on top of the tank? A. I guess I did.

Q. Did you put old clothes on? A. I was working around the garage. I was asked if I wanted to go down the street. I said yes. I didn't have any clothes for it.

Q. What do the tanks look like? A. Wooden storage tanks.

Q. Any oil on them, around them or in them? A. I didn't notice any oil.

Q. How did the acid look? Did it look clear and clean? A. Yes.

Q. What time of day was it? A. I don't remember exactly. It was probably, oh, around dusk, probably eight or nine o'clock.

Q. Eight or nine o'clock in December in Michigan you can see what acid looks like in a tank? A. No. It might have been later than that. I don't remember the exact time.

Q. Well, you don't know what it looked like inside the tank then, do you? A. No, I thought you meant when I got the acid out. You can't, of course, see down a tank.

Q. What did you lower into the tank? A. Lowered a clean glass quart jar.

Q. Did you have it on a bail or hook or something? A. Yes.

ROSE GILROY,

a witness called by plaintiff, testified as follows, by deposition:

DIRECT EXAMINATION

I live at 1713 Sayre Street, Midland, Michigan, and am secretary to the general counsel of The Dow Chemical Company. I remember one night in August, 1938, that Mr. Shelley and Mr. Hardy and Mr. Conner met me at the offices of The Dow Chemical Company in Midland with samples in glass bottles. These samples were put in the vault of the Legal Department. Then I locked the vault in their presence. That was in August, 1938. I have a way of fixing the date because I was called away from a dinner party. The samples consisted of a number of glass bottles which were labeled. I do not know who labeled them or what was in them. The contents of the bottles were liquid.

That is not the only occasion on which Mr. Shelley, Mr. Hardy or Mr. Conner delivered samples to me. About a month or so later, these gentlemen brought another quantity of labeled glass bottles and these also were put in the vault in the presence of these gentlemen. That was in 1938. I cannot give the month, but I would say about a month or so after the first batch.

LEONARD C. CHAMBERLAIN,

a witness called by plaintiff, testified as follows, by deposition:

DIRECT EXAMINATION

I live in Midland, Michigan, and have been employed by The Dow Chemical Company since 1928 as a research engineer. During the month of June, 1939, I attended the taking of depositions at Mt. Pleasant, Michigan, in this case and obtained a piece of lead from defendant. When the depositions were over, we went to the Halliburton warehouse at Mt. Pleasant, where one of the Halliburton men gave me this lead strip. I put it in my car and brought it back to Midland and tagged it with pertinent information concerning where I obtained it and put it in the vault here in Midland. I prepared a label for the lead strip so it could later be identified, which label contained the information that this lead strip was obtained that day from the Halliburton Oil Well Cementing Company representative and that I received it and brought it to Midland. I signed the label and attached it to the lead strip. This lead strip was put in the vault in the office of Mr. Campbell.

Q. Do you know the name of the party representing Halliburton who gave you the lead strip? A. Well, there were several of them there. I think Mr. Edwards was there.

Q. Mr. Edwards is here today. Is he the gentleman? A. I think you were there (witness addressing Mr. Conner). I think Babcock and Edwards were both there.

Witness (to Mr. Babcock): Weren't you there?

Mr. Babcock: I actually don't know that we gave you one there. I mailed you one.

By Mr. Conner:

During the depositions in 1939 in Mt. Pleasant you offered us a lead strip such as is used in the tank as an

electrode, and we accepted it according to the testimony of Mr. Chamberlain.

Q. At the time this lead strip was given to you what, if anything, was said to you by any of the Halliburton representatives as to the use that they made of such or similar lead strips? A. Well, it was the remainder of a strip which they said they hung in their tanks during the polarization of the tanks.

Q. Was this a strip which had or had not been used, do you know? A. It was supposed to have been used.

CROSS EXAMINATION

I did not test this lead strip to see what it was chemically. I do not know where the lead strip is now.

DONALD L. CONNER,

a witness produced on behalf of plaintiff, testified as follows:

DIRECT EXAMINATION

I live in Tulsa, Oklahoma, and am a lawyer employed by The Dow Chemical Company, stationed at Tulsa, Oklahoma. I am the Mr. Conner to whom several witnesses have testified they delivered certain samples.

On August 5, 1938, E. G. Hardy and myself met Paul Shelley and Messrs. W. L. and J. E. Steelman at the home

of J. E. Steelman outside West Branch, Michigan. We met them late in the afternoon as I recall, and J. E. Steelman, I think, turned over to Mr. Shelley two stoneware jugs of liquid. I was present when Mr. Steelman turned these jugs over to Shelley and Hardy. These two jugs, which I was told contained liquid hydrochloric acid, were put into four one-half gallon jugs with glass stoppers and sealed. I observed Shelley write out labels for each of these four bottles of acid which had come from the jugs. The labels, which I saw him write and have observed since, showed what acid it was, where it came from, who supplied the acid, identified the well, and gave the date. Those samples were sealed. Shelley signed each one of them and Hardy signed the label in each instance, showing Shelley had sealed the sample and that Hardy was a witness to the sealing of the sample. In this case, the Stella Wilcox well, Mr. Steelman signed the label. That gave us four one-half gallon jars of acid as samples taken from the treatment of that well. I was present at Mr. Steelman's home when the jugs of acid were brought in from the well.

In each instance, when the Wilcox well was treated on August 5th, the Zahn well on August 19th, and the Crawford well on September 10th, for the Weber Oil Company by Halliburton, I was present in Mr. Steelman's yard, and either Mr. Steelman turned the samples over to Shelley or Shelley brought the sample with him. I want to correct my testimony. I was not present when the samples from the Zahn well were delivered, but I was present when the samples were delivered from the Stella Wilcox and the Crawford wells.

I had nothing to do with the preparation of the labels so far as the physical making of the labels was concerned, but I did direct Shelley as to the wording of the labels, and in each case I or Shelley wrote up in the corner of the label a key number which would then enable us to identify and refer to the sample in a more brief manner. In the treatment of the Wilcox well on August 5th, these acid samples put into the one-half gallon bottles were numbered 5, 6, 7 and 8.

I am pretty sure I was not present at the Zahn well when the samples were taken. I can find out in a few minutes by looking at the expense reports. My recollection is that I was in Oklahoma. I have knowledge of those samples to this extent: I was present in Midland, Michigan, practically all of the summer of 1938. I am pretty sure I must have been here, although I would rather look at my expense records.

(Witness left to examine records.)

My recollection has now returned and I definitely recall that I was not present during the treatment of the Zahn well. I had something to do with the marking of samples, which bore labels indicating that they came from the Zahn well. I recall that during the latter part of August, 1938, when I came to Midland on one of my trips, I contacted Mr. Paul Shelley and he had previously told me that when the Zahn well of Weber's was treated on August 19th he obtained on that date a sample of both the acid and the blanket used in the treatment of that well. Shelley contacted me and together we went into the plant of The Dow Chemical Company to Building No. 280, where we opened up a vault and took out of there some samples that he told me was acid, and some material that he told me was blanket, and we brought them over to the Legal Department office. Those samples of acid and blanket had been labeled in the handwriting of Shelley to show where the materials came from, on what date, what well, who obtained them, and sealed them, and what not. I recall that the label showed there were three one-half gallon bottles and the label said substantially that they were hydrochloric acid, part of the acid put into the Zahn well by the Halliburton Oil Well Cementing Company, and the label went on to say that it was brought to the well by the Halliburton Oil Well Cementing Company, each label was signed by Shelley to show he had sealed them and further signed by E. P. Hardy showing he had witnessed it.

Either I marked or I instructed Shelley to mark up in one corner of the labels on these acid samples, the num-

bers 12, 12A and 12B, there being three one-half gallon samples. Shelley and I, after getting them from 280 Building in the plant, brought them to the vault in the Legal Department office. I was with him when he brought them from 280 Building over to the office, and that was the latter part of August.

I was present at the time samples of acid were obtained from the Crawford well, I was present in the yard of Mr. J. E. Steelman at West Branch or I was present with Shelley and Hardy near the well. I don't recall whether it was actually Mr. Steelman's yard or some place near the well where J. E. Steelman or Wesley Steelman, one of the two, gave to Shelley those two one-gallon stoneware jugs containing the acid. We took those jugs, Shelley, Hardy and myself, and Shelley and Hardy poured the acid out of the stoneware jugs into four one-half gallon bottles, stoppered and sealed them, and prepared labels showing from which well they had obtained them, all similar to the other labels. Those samples were marked as samples Nos. 15, 15A and 15B, and I was with Shelley and Hardy when those samples were delivered to the vault of the Legal Department of The Dow Chemical Company at Midland, Michigan. This was done on the very same date, September 10, 1938, that the samples were taken. I recall that very accurately because I left town that night to go back to Oklahoma.

I had something to do with the samples of acid which were obtained by Mr. Day and Mr. Forsman from the Halliburton storage tanks at Mt. Pleasant. I requested of them some time in August that they obtain samples from the wooden storage tanks of Halliburton, which I was told had acid in them and were located on North Franklin Street, Mt. Pleasant, Michigan, on August 18. I remember that date very clearly because it was the day before the Zahn well was treated, I think. On August 19th, Mr. Day and Mr. Forsman brought to me at the Midland office of The Dow Chemical Company, two bottles containing a liquid which they said was hydrochloric acid, each bottle

having attached to it a sticker. If my memory serves me rightly, it was a white sticker with a red border around it, showing one sample came from the north tank and the other showing it came from the south tank, containing the date on which the samples were obtained, and each of those labels were signed by Day and by Forsman. At the time I first saw the bottles, I examined them and marked up in the corner that one sample that came from the north tank, as 14N, and the one from the south as 14S, and so marked that on each of the labels. On that same date, I think it was, I contacted Paul Shelley and had him come to me at the office and, at my direction, Shelley took the north and south samples, and he split them into three parts, stoppered and sealed them. In addition a label was prepared showing where they came from. That label was put on each of the three portions and Shelley signed it. On one of the portions of the sample, 14S and 14N, there was attached the original label that had been on the containers in which they were delivered. When the 14N sample was split, it was then called N-14 for the first portion, N-14-A for the second portion, and N-14-B for the third portion. With respect to the S-14 sample, when it was split the first portion was marked S-14, the second S-14-A, and the third portion S-14-B, and placed them in the vault; all done on August 19th. Later I received additional samples from Mr. Day.

On December 6th, Mr. Day and Mr. Forsman brought me two samples of what they said was hydrochloric acid in two different containers, each labeled showing where it came from and how they got it. As to those samples, I marked one N-20, showing it came from the north storage tank of the Halliburton Oil Well Cementing Company at Mt. Pleasant, according to the label they had prepared, and the other S-20. On that same day, if not the next, as in the previous case with the series No. 14 samples, we took the two samples marked N-20 and S-20, split each into three portions, the S portions being marked S-20, S-20-A and S-20-B, and the N portions being marked N-20, N-20-A

and N-20-B. On each of the six portions, there was a label prepared based on a label that was on the original container. Mr. Shelley prepared the label and signed it. On one each of the portions, we attached the label Day and Forsman originally had applied to those samples. After those samples were so marked, Shelley and I put them in the vault of the Legal Department at Midland.

CROSS EXAMINATION

By Mr. Babcock:

Q. Who has access to this vault in Building 280? A. That I don't know. It is in the Physical Research Laboratory Building so far as I remember. I have only been in the plant, oh, probably just on a very few occasions, and I wouldn't have the slightest idea who has access to that vault except Shelley. I would presume Mr. Chamberlain, his superior, would, and other than that I don't know.

REDIRECT EXAMINATION

I have a correction or addition to make to the statement in my testimony yesterday referring to a sample Day delivered to me in December, 1938, as sample No. 20: In December of 1938, Mr. Day and Mr. Forsman delivered to me two bottles of liquid which they said was acid taken from the Halliburton storage tanks at Mt. Pleasant, Michigan. These samples, both of them, were labeled when I received them from Mr. Day and Mr. Forsman and the label showed what date the samples were taken, which was December 6, 1938, the labels further showing where the samples came from and further showing who obtained the samples, and bore the names of Day and Forsman, who both then signed the labels. When I received those samples, Mr. Shelley and I, in splitting them, erroneously marked them as samples Nos. 17-S and N, and it later developed that we already had obtained a sample which we had labeled No. 17, giving us duplicate sample numbers 17.

To correct that situation, I then directed that these storage samples should be renumbered as series 20. That is, they were then numbered N-20, N-20-A, and N-20-B, and the other portion was numbered S-20, S-20-A, and S-20-B, thus making a correction to our numbering of the samples. However, this change had nothing to do with changing anything on the label, which was a true indication of where the samples came from and what not. When these samples were received by me I did not first mark them N-20 and S-20. I may have made my statement a little incorrect at first. When I first received them I marked them S-17 and N-17, A's and B's to each. Finding I already had among my samples a sample marked N-17, which I had previously obtained, I then corrected this latter set of samples, which were the storage samples, and changed their mark from the series 17 to series 20.

I don't recall the exact time interval after the original marking of the N and S-17 numbers and when I changed them to N-20 and S-20. However, I think it was a very short period of probably two or three days. I then and am now keeping a constant chart of numbers I applied to the samples and I think when revising the list as to the numbers, I found I had already numbered one 17. So I would say roughly it was within two or three days.

Mr. Lyon: I just want to make a remark. Counsel for the plaintiff has now offered the depositions of ten witnesses in regard to formal matter, that is, the obtaining of samples on these four wells which were the subject of a discussion this afternoon, and although these witnesses are available in the district, I am willing that their depositions should be taken with the same force and effect as if they were called to testify, but I would like to reserve my objection to this testimony, the same objection that I am making on this subject.

The Court: You may have that, and I will overrule it and you have an exception.

Mr. Owen: Now, the next step, Your Honor, pertains to the transmission of these samples, which by these depo-

sitions were traced to the vault of The Dow Chemical Company—the next step is to get them from The Dow Chemical Company into the hands of Dr. Bartell, our expert. We have here some affidavits of some men that they delivered them to Dr. Bartell and his affidavit that he received them.

Mr. Lyon: I am willing that these affidavits should be received in evidence with the same force and effect as if the witnesses named in the affidavits were called and testified to the facts in the affidavits.

The following affidavits of Leonard C. Chamberlain, Donald L. Conner, Edward C. Hardy and Floyd E. Bartell were offered and received in evidence.

AFFIDAVIT OF LEONARD C. CHAMBERLAIN

I am a resident of Midland, in the County of Midland, State of Michigan, my address is Isabella Road, and I am employed by The Dow Chemical Company at Midland, Michigan as a research engineer.

On July 6, 1939, and August 31, 1939, upon instructions from The Dow Chemical Company, Legal Department, I removed certain packages and glass bottles containing samples of materials from the vault in the main office of The Dow Chemical Company at Midland, Michigan, and transported them to Ann Arbor, Michigan, where I delivered them to the office of Dr. Floyd E. Bartell, Department of Physical Chemistry, at the University of Michigan.

AFFIDAVIT OF DONALD L. CONNER

I am a resident of Tulsa, in the County of Tulsa, State of Oklahoma, my address is 215 East 27th Street, and I am employed by The Dow Chemical Company of Midland, Michigan, as a lawyer.

On August 24, 1938, and April 25, 1939, I removed certain glass bottles containing samples of materials from the vault in the main office of The Dow Chemical Company at Midland, Michigan, and transported them to Ann Arbor, Michigan, where I delivered them to the office of Dr. Floyd E. Bartell, Department of Physical Chemistry, at the University of Michigan.

AFFIDAVIT OF EDWARD C. HARDY

I am a resident of Mt. Pleasant, in the County of Isabella, State of Michigan, my address is 503 East Chippewa Street, and I am employed by Dowell Incorporated as station manager at Mt. Pleasant, Michigan.

On September 15, 1938, upon instructions from The Dow Chemical Company, Legal Department, I removed certain glass bottles containing samples of materials from the vault in the main office of The Dow Chemical Company at Midland, Michigan, and transported them to Ann Arbor, Michigan, where I delivered them to the office of Dr. Floyd E. Bartell, Department of Physical Chemistry, at the University of Michigan.

AFFIDAVIT OF FLOYD E. BARTELL

I am a resident of Ann Arbor, in the County of Washtenaw, State of Michigan, my address is care of the University of Michigan, and I am Professor of Chemistry at the University of Michigan located at Ann Arbor, Michigan.

I was in Midland, Michigan, at the office of The Dow Chemical Company at various times within the last several years and there on the dates indicated received from the Legal Department of The Dow Chemical Company samples of various materials bearing the numbers as follows:

No. 5	August 23, 1939
No. 6	August 23, 1939
No. 8	August 8, 1938
No. 12	August 23, 1939
No. 15	August 23, 1939

Additionally I have received from various persons of The Dow Chemical Company other samples of materials bearing certain numbers which were delivered to me at my office at the University of Michigan at Ann Arbor, Michigan, by the persons and on the dates indicated:

No. 12-B, August 24, 1938, delivered by D. L. Conner.

No. 15, August 31, 1939, delivered by L. C. Chamberlain.

No. N-14-B, September 15, 1938, delivered by E. C. Hardy.

No. S-14-B, September 15, 1938, delivered by E. C. Hardy.

Additionally, on December 14, 1938, I received samples of material marked Samples Nos. N-17-B and S-17-B from The Dow Chemical Company which samples came to me by express.

DR. FLOYD E. BARTELL,

a witness called by plaintiff, testified as follows:

DIRECT EXAMINATION

I am Professor of Chemistry at the University of Michigan, occupying the position since 1910. In this position I am responsible for the work of the department of general and physical chemistry, conduct classes in physical chemistry including colloid and surface chemistry, and direct the research of numerous graduate students. I have a Bachelor's Degree, a Master's Degree and the Degree of Doctor of Philosophy, the last two from the University of Michigan.

I have had numerous occasions to study patents and am familiar with the Grebe-Sanford patent 1,877,504, having studied it in connection with my work in this case. I understand the patent to relate to the treatment of deep wells, such as oil, gas, brine or water wells for the purpose of increasing their yield, particularly those in a mineral bearing stratum consisting of limestone or other calcareous formations.

The principal object of the invention is to counteract in some way effects which may have come about which have tended to decrease the yield or output of the wells. The patent points out in some cases the output may have decreased to such an extent that further operation has become unprofitable. The idea is to introduce into such wells a solution containing acid or consisting largely of an aqueous solution of hydrochloric acid, which will react with the formation, increasing the size of the openings or crevices.

The next point mentioned in the patent is that in carrying out the method an acid is employed, preferably hydrochloric acid, to which is added a small amount of a substance which is capable of inhibiting the attack of the acid

upon metal surfaces, such as upon surfaces of iron or steel. No mention is made at that point as to why that is desirable but it is pointed out that it is desirable. Mention is made as to inhibiting agents used, a preferable one being an arsenic compound soluble in the acid solution, such as arsenic acid, arsenic trioxide or soluble arsenate. It is pointed out, also, other inhibitors may be used, such as cyanides, organic nitrogen bases such as aniline, phenylhydrazine, pyridine, quinoline, acridine and derivatives thereof, organic sulphur compounds, such as mercaptans, as well as various by-products of industrial processes. Then the patent goes on to mention that the strength of the aqueous hydrochloric acid solution which is preferable is between 5 and 20%—I should say the preferable concentration really between 10 and 15%, although other concentrations may be used.

Then the author of the patent goes on to mention how the acid may be added. The acid solution is preferably added in an amount calculated to fill the bore of the well to a depth not exceeding the thickness of the mineral bearing stratum, and points out to force the charge of acid out of the pump tube into the bore of the well against the head of the oil standing in the well it may be necessary to introduce pressure to force out the acid by pressure or other suitable means, as by a pump. After the acid has reacted with calcareous material and has practically ceased, it is suggested that the spent solution may be removed from the well by pumping or by bailing out. An example is given of the practical use of the method in the Central Michigan oil fields. I don't know that it is necessary to go over the amounts of materials used. It is suggested that 15% hydrochloric acid solution might be used with 2 gallons of arsenic acid, 4500 pounds total of the acid, and 2 gallons of arsenic calculated as As_2O_5. It is suggested that this mixed solution can be charged into the oil well through the iron pipe tube; that this may be followed by a quantity of crude oil to force the acid out of the bottom of the tube into the well, and then after the acid has become exhausted may be

pumped out and thereupon regular pumping of the oil may be resumed. In the case mentioned in the application in the Michigan field, it was stated that the production of the well treated was approximately doubled with one treatment.

Then the patent further states the method has been used repeatedly for the treatment of low yield or exhausted oil wells in territories, with resulting increase in output resulting from 75 to 200%, and that in some cases that the wells which have ceased to flow have been brought back to the resumption of the natural flow.

On page 1, line 43, it is pointed out—"As an illustration, a chemical method is described in United States Patent 556,669, according to which the flow of an oil well in a limestone formation is increased by treating with a quantity of an acid, such as hydrochloric acid."

The Court: Well, now, what new do they claim? What improvement do they claim they made over that? How do they claim they change? A. My understanding is that the main claim for improvement is the addition to the hydrochloric acid of some material which will inhibit the action of the acid.

The Court: There is no claim that the acid, for instance, in this well, would not have done just as good a job as if it had not gone into it— A. I do not believe so.

The Court: They do not claim any new useful result. They just claim to have avoided a misfortune. A. The useful result would be limited apparently to the equipment, rather than to the well itself.

The Court: As far as increasing the flow of the well, and all of that, they do not claim to have accomplished anything? A. I don't think so.

The Court: But simply to have avoided a misfortune? A. I think so. Inhibitors, such as are suggested here, as far as I know, would have no effect on the acid, in connection with its reaction upon limestone.

The Court: All right. In other words, it has absolutely,—the adding of this has no effect that we know anything about or claim anything about on the work which

is desired to be done in treating the well? A. That is my understanding. But, it does have a specific function on the metal equipment used in connection with the well treatment.

By Mr. Owen:

Q. Would you say, Doctor, whether or not the presence of an inhibitor in the acid, which will prevent or restrict its reaction on the pipe and other well equipment, would have any bearing on the strength of the acid which goes into the formation? A. As I understand the question, the answer is "No." That is to say, the mere presence of the inhibitor in the acid would have no effect on the strength or work the acid would subsequently be able to do.

Q. Would an uninhibited acid which attacks the metal reach the formation in the full strength in which it was introduced into the well tubing? A. No, it would not. Some of the acid would be expended by reaction with the metal of the well tubing.

The Court: What fraction of one per cent do you think it would be diminished? Surely not more than one, not above; it would be a fraction of one per cent of your total acid as it went down into your well, wouldn't it? Don't you think it would be less than one per cent that would be diminished? A. Well, it would depend on the rate at which the acid were added and the amount added and the method of handling it in general. That would vary, of course, with treatments, depending on the amount of acid used in a specific treatment as well as the method in which it was used.

The Court: Which does it like better, iron or lime? A. It will react more rapidly, ordinarily, with lime.

By Mr. Owen:

Q. Have you tested and analyzed any samples of hydrochloric acid solutions for the Dow Chemical Company during the past two or three years, which you understood to have been some of the acid used by the defendant in this case, the Halliburton Oil Well Cementing Company, in treating wells in the Central Michigan fields? A. We have.

Mr. Owen: I will state for Your Honor's information that some of the depositions which were offered in this case and were not read dealt with the obtaining of the samples from the oil wells and sealing and delivery to the vault of The Dow Chemical Company, and then there were affidavits signed by the men who delivered those samples from the Dow Chemical vault to Dr. Bartell and Dr. Bartell's affidavit that he had received them, and it was stipulated that if those witnesses were called they would so testify.

Mr. Lyon: That is correct.

The Court: I am satisfied as to the identity of the samples.

Mr. Owen: It was just to trace the samples from the Halliburton tanks to the laboratory of Dr. Bartell.

The Court: I am satisfied with that proof.

By Mr. Owen:

Q. Who, if anyone, assisted you in making the analyses of these samples? A. Dr. Paul H. Cardwell.

(Dr. Cardwell was present and also was sworn as a witness.)

Q. What has been Dr. Cardwell's education and training? A. He received the Bachelor's degree at Central State Teacher's College in 1935. He entered the graduate school of the University of Michigan in 1936, received the Master's degree about a year later, and then served as assistant in the department, Teaching Fellow, and obtained his Doctor's degree in June of the present year, 1941. He has specialized in chemistry during all of his graduate work.

Q. It is in evidence that samples of acid taken from defendant's truck tanks during its acid treatments of the Stella Wilcox well on August 5, 1938, of the Zahn well on August 19, 1938, and of the Crawford well on September 10, 1938, all in Ogemaw County, Michigan, were delivered to you; the Stella Wilcox samples being numbered 5, 6 and 8, the Zahn samples being numbered 12 and 12-B, and the Crawford samples, two in number, being numbered 15. Will you state whether or not you received such samples? A. I did receive such samples, with the same numbers as mentioned.

Mr. Lyon: May it be understood that any testimony regarding these samples is subject to the objection heretofore made, without the necessity of further repeating that objection? That is the objection as to the fact that those wells were treated on the authority of and with the consent of the Dow Company.

The Court: Yes. I will overrule that objection, so you may have the benefit of having objected to the question, and I give you an exception to it all the way through.

By Mr. Owen:

Q. What, if any, instructions did you receive in connection with those samples? A. I was instructed to examine them, to determine whether they contained hydrochloric acid, and the approximate strength, if the acid proved to be hydrochloric acid, and to make corrosion studies to determine whether or not these samples of acid contained a material which served as an inhibitor, in so far as the corrosive effect against iron or steel was concerned. Each of these samples contained hydrochloric acid of approximately fifteen per cent concentration.

Mr. Lyon: I am not interested in that analysis. There is no question about the defendant using hydrochloric acid.

The Witness: We were requested to test the samples and determine their corrosive action on iron or steel, and naturally we expected to compare the action of these acids with acids which we knew to contain no inhibitor, and the test we were to make was for the purpose of determining whether or not these acids contained a substance which functioned as an inhibiting agent. And, so, to make the test that was requested to determine whether or not these samples contained material which functioned as an inhibiting agent, the thing we did was to obtain chemically pure hydrochloric acid, make up solutions of strength identical to that of each of the samples mentioned, and test them side by side, figuratively, to determine the corrosive action of the chemically pure acid in solution with that of the oil well sample solution and note their reactivity on the metal. Perhaps I should make a statement before starting in, which may save

me embarrassment later. Naturally, the amount of samples we had was limited; otherwise we could have made, perhaps, elaborate tests. But we had, as I recall, not over about a liter of each of the samples. A liter is in the neighborhood of a quart. So we had to regulate our set of experiments accordingly.

In setting up the experiments we decided to use about 50 c.c. for each test, since it would be desirable to run a number of duplicate samples. That would fill perhaps a two-ounce bottle. The acid was placed in small wide-mouthed bottles. They were about 3 inches in height and an inch and a quarter by an inch and a quarter in width. The metal pieces used for testing were rectangular pieces 1" x 7/8" by 1/8" thick. In the first series of tests which I will mention, these pieces were cut from strap iron. A small hole was drilled through the metal at one end near the middle or center so that the strip could be suspended in the liquid. The strip was suspended by means of a glass support so the acid would not react on it. In the first series of tests, the solutions were not agitated. The experiments were carried out at a temperature of 85 degrees Fahrenheit, and the time of the tests was 16 hours.

The Court: As I understand it, you had one of these containers with the acid that came from the defendants, and then one of acid that was not inhibited? A. That is right.

The Court: And you took the same length of time, and the experiments were made under identical conditions? A. Under identical conditions, treated in the same manner just as far as it was possible.

Mr. Lyon: There is just one bottle of defendant's acid in this, and one bottle of chemically pure acid, is that right? A. No, that represents a single test. Duplicates were always run of not less than five, or three at least, not less than three at least of each.

The metal strips were sawed from about an inch wide strap iron, and then were sand-blasted, for cleaning, and were not touched after the sand-blasting, that is, touched by hand, or in any way on the surface.

By Mr. Owen:

Q. You did not give the strength of the samples of defendant's acid, can you give that? A. I can. The strength of sample 8, as indicated on my notes, was 14.8 per cent, that is the sample for the Stella Wilcox, 14.8. Sample 6 Stella Wilcox, 14.8.

The Court: They were taken out of the same tank, as I understand it.

Mr. Owen: That is right.

A. Of course, there might have been a slight variation if the sample bottle was dipped into the tank at different points, or stirred up the material after dipping. I don't say there was any reason why the samples should analyze exactly the same.

Mr. Lyon: Do I understand, Mr. Owen, the plaintiff took one two-gallon sample or took two one-gallon samples?

Mr. Owen: Two one-gallon samples.

By Mr. Owen:

Q. What was the strength of the other samples? A. The sample indicated as 12-B was 14.5 per cent, and the sample indicated as 12 also 14.5 per cent. From the Crawford well, we had two different samples which happened to carry the same number, 15. They were obtained by us at slightly different times. They both were of 15.2 per cent concentration.

The Court: That comes out the way we would expect. There isn't exact uniformity between wells.

Mr. Owen: That is right.

The Court: But as to samples from the same wells, complete uniformity. It so happens, as you point out, we wouldn't be greatly disturbed or surprised if there had been a little difference, but there wasn't any. A. That is right, Your Honor.

The Court: They had them pretty well mixed, in other words.

Mr. Owen: The truck had traveled, I think, 60 or 70 or 80 miles, and they probably were pretty thoroughly mixed.

The Witness: By blank samples we refer to samples of the acid that we made up by using chemically pure acid with water, of the same acid strength as the particular tank sample. For the Stella Wilcox well we prepared but one blank, since all of the acid samples were of the same strength, namely, 14.8 per cent. That is true also of the Zahn well and the Crawford well. I have tabulated the results of our comparative corrosion tests made with the samples of defendant's treating acids and with these blanks which we prepared. I have such data in form indicated as table I.

Mr. Owen: I offer this table in evidence as Exhibit PX-154.

A. In this table I recorded the results obtained in corrosion tests, as described; namely, with metal strips of strap iron of approximately 1 inch by 7/8ths inch by 1/8th inch, with the solutions as indicated in the first column of the table. The experiments were all carried out at 85 degrees Fahrenheit, using 50 c.c. of the acid solutions. The tests were all carried for the same length of time, in this case 16 hours. The metals used are from two batches of strap iron, one marked Series B and the other Series D. It happened to be that those were from different pieces of strap iron. In the second column of the chart is represented the per cent of hydrochloric acid. In the third column is represented the initial weight of the metal strips. In the fourth column, the final weight, that is to say, the weight after the action of the acid upon the iron. In the fifth column is given the loss in weight. In the sixth column the per cent loss in weight. In the seventh column the calculated per cent reduction in corrosiveness. I will explain the meaning of that seventh column later.

As an example, in one series of tests with Sample 8, Stella Wilcox, a single experiment gave these data: The initial weight of the strip was 14.4300 grams. The weight after action of the acid indicated as final weight 14.1386. The loss in weight 0.2914 grams. Or the per cent loss in weight would be 2.02.

Now, the average values, obtained by three sets of tests as indicated, gave as an initial weight 14.4308 grams. The final weight 14.1415 grams. The loss in weight 0.2893 grams. The average per cent loss in weight 2.01. And it would be noted that the average per cent loss in weight was practically the same as the per cent loss in weight of the single sample first mentioned.

In the second series of tests, using blank acid of the same strength as Sample 8, and referred to as "Blank 8 C. P. HCl.," the average initial weight in grams of three samples was 14.4287. The final weight in grams average was 13.8816. The average loss in weight of the three samples 0.5471 grams. Or a per cent loss in weight of 3.79.

I think perhaps the simplest way to represent what is meant by per cent reduction in corrosiveness, and how the figure 47 in the last column was obtained, would be to represent it in this way: It will be noted that the average per cent loss in weight of Sample 8 was 2.01, and the average per cent loss in weight of the corresponding blank was 3.79. Now that represents the ratio of per cent loss in weight. Now if one lets the loss in weight obtained with the chemically pure acid be represented by 100 per cent, one then would have the ratio of 2.01 is to 3.79 as x is to 100, and the x would represent then the relative corrosiveness of the sample acid. Now, in that case x would represent and be equal to 53. Or 2.01 is to 3.79 as 53 is to 100.

The Court: Well, is the 47 per cent of 3.79? A. The corrosiveness would be as 53 is to 100. The reduction in corrosiveness then would be 100 minus 53 or 47. The 47 would represent the reduction in corrosiveness of the sample acid as against the CP acid. Or, suppose we were to represent that diagrammatically. If one were to represent the amount of corrosion of the C. P. acid by a straight line and let that line represent 100 per cent, the corrosiveness of the sample acid would end out here at 53 and the reduction in corrosiveness would be represented by the value 47. So setting it up in that way it is fair to state that the reduction in corrosiveness was 47 per cent. The amount

of corrosion would be dependent on the surface area, but it happens these small pieces were cut all to the same size and so had practically the same surface.

We followed the same procedure with respect to each one of those different samples as I have explained with respect to Sample No. 8. The sample indicated as 12-B from the Zahn well showed a reduction in corrosiveness over that of the CP acid of 48%. The corrosiveness was 52% that of the corrosiveness of the CP acid, or the reduction in corrosiveness was 48%. The Stella Wilcox sample No. 5 showed a reduction in corrosiveness over that of the CP acid of 42%. Stella Wilcox sample No. 6 showed a reduction in corrosiveness of 42%. The Zahn sample No. 12 showed a reduction in corrosiveness of 42%, and one of the Crawford samples No. 15 showed a reduction in corrosiveness of 69%, and the other one 71%. Approximately the same.

By Mr. Owen:

Q. Well, now, I understand that samples No. 8 and No. 5 and No. 6 came from the same well, the Stella Wilcox, and from the two-gallon sample of defendant's acid which was taken at that time. Will you explain, if you can, the difference in corrosiveness or reductions in corrosiveness which you have found for those different samples? A. Well, since the acid content of those samples is the same throughout, it must be that there is a slight variation in some other constituent present in the samples.

Q. Did you make any other tests with these same samples of defendant's acids and the corresponding blanks? A. Yes.

Mr. Lyon: I don't understand what the bottom figures are. Average 15 blank, and then there are 3 blank fifteens in there. What is the significance of those? A. Well, the average of 15, the figure indicated by that, would come over in the fifth column, which is 0.2454%. That means that the average of two samples 15 had a value of 0.2454% loss in weight.

Mr. Lyon: No. I was asking about 3 at the bottom,

Dr. Bartell. I don't understand what blanks those were that were added together under that title Blank 15 CP. Then there is another one and another one. What 3 blanks were those? A. Oh, those were simply separate tests with the same concentration of acid but using different pieces of metal. You see in the column 3, the initial weight in grams is slightly different, indicating that separate tests were made, 3 distinct tests with that particular sample of acid.

Mr. Lyon: Well, can you explain to us again why the per cent loss in weight on those 3 blanks average 5.73, while the blanks up in series D seem to be around 3 and 3.5; or thereabouts? A. Would this be a fair question as to why the per cent loss in weight shown by the blanks 15 are higher than the per cent loss of weight shown by the earlier blanks?

Mr. Lyon: Yes, that is why I am trying—(Witness interposing) Well, if you use the question, I think a fair answer would be that probably the two series of metals used were of slightly different composition and had different rates of corrosion.

Mr. Lyon: They weren't cut out of the same metal? A. No. Series D was cut out from one strip of strap iron; Series B another. So the iron differed slightly.

By Mr. Owen:

Q. Now, I asked you if you made any similar tests with these acids using other materials, and I believe you stated that you did. Will you refer to those tests, and if you have any table showing them, will you produce that table? A. We have made similar tests with other materials, with metal strips cut from oil well pipes. We obtained oil well pipe from the National Supply Company, from the Oil Well Supply Company, and from the Atha Supply Company. We have data corresponding to the data given for the experiments made with strap iron, for metal strips of approximately the same size as those used of the strap iron material, but cut from oil well pipe.

The metal pieces were approximately, in the case of

the National Supply Company pipe, one inch by 7/8ths by 3/16ths. The thickness of the pipe of the different companies was all practically the same, all practically 3/16ths, and the other dimensions were 1 by 7/8ths, the same. The same amount of solution, of the acid solution, was used as was used previously, namely, 50 c.c. The experiments were carried out at 85 degrees Fahrenheit, and the tests were again run for a period of 16 hours.

Mr. Owen: The table showing the results of those tests is offered as PX-155.

By Mr. Owen:

Q. Will you explain what this Exhibit PX-155 shows? A. That shows the results obtained in corrosion tests, using the National Supply Company pipe material, with the different acid samples. We followed the same procedure as we did with the strips of strap iron which I have already explained. We prepared blanks of C. P. acid, of strengths corresponding to each of the oil well samples, and carried out the experiments in exactly the same manner.

PX-155 relates only to the tests made with the National Supply Company pipe. I also have tables showing the results of our tests with the other two pipe samples. The results obtained with the Oil Well Supply Company pipe material are shown in Table III.

Mr. Owen: That will be offered in evidence as PX-156.

The Court: Let me see about PX-155. This differs from the other only in that you used different materials for the acid to eat on? A. That is right, Your Honor. That is the only difference between this and PX-154. The pieces of metal were essentially the same size, but different kind or quality. And the acids were the same, and we took the same length of time, 16 hours, but it was different metal, oil well tubing instead of strap iron.

The Court: I can't compare the results, can I, on account of the shape? Wasn't that different? A. The shape was practically the same except the thickness was just a little different, because the thickness of the pipe was a little different than the thickness of the strap iron. The pipe was

a little thicker. The strap iron was 1/8th of an inch thick, and the pipe about 3/16ths.

The Court: There wasn't as much difference in percentage? A. That is true.

The Court: And, how do I know but what that is all due to the difference in the shape? A. Well, I can very quickly, Your Honor, give you the relative ratios of those surfaces of the metals, if you wish, and they are so nearly the same that that would not quite account for the difference that occurs in the corrosiveness. The area, surface area as calculated for the surface of the strap iron strips was 14.58 square centimeters. For the National Supply Company pipe, 14.52 square centimeters. The area of the Oil Well Supply Company sample was 14.52 centimeters square, and the surface area of the remaining sample cut from the Atha pipe was 15.33 square centimeters. So, it will be noted there is not a great difference in the surface area altogether.

Mr. Lyon: Just so the record will be clear, Doctor, these samples on which these tests were made were immersed in the acid so that the metal strips or specimens were contacted with the acid on both sides of the metal, were they not? A. On all sides, yes. The area I am giving you represents the total area exposed on all sides.

Mr. Lyon: And were these other pieces of metal in Tables II and III, and similar tables, all sand-blasted before— A. (Interrupting): They were all treated in exactly the same way.

The activity of both the oil well sample acid, and the blank acid, the action was greater with the oil well pipe than with the strap iron.

Mr. Owen: Table IV, showing the results of tests with Atha Supply Company pipe is offered as PX-157.

By Mr. Owen:

Q. As I understand you, these results or these tests, the results of which are shown in your tables numbered I, II, III and IV, which are in evidence as PX-154, 155, 156 and 157, represent the results of similar tests with four different metals? A. That is right.

Q. And the only difference in the tests was in the metal used? A. Yes, so far as we could control the experiments.

Q. Are you able to give the average reduction in corrosiveness in the tests made with strap iron as between chemically pure acid and the several samples obtained from the defendant's treating tanks? A. Yes, I think so. With the strap iron the average percentage reduction in corrosiveness of Samples 5, 6 and 8 from the Stella Wilcox well, gave a value of 44 as per cent reduction in corrosiveness. The average reduction in corrosiveness of all seven samples shown in PX-154 is 52 per cent.

The Court: That is the average of the samples taken from the wells? A. That is right, Your Honor. The reduction in corrosiveness was obtained for each of the seven samples and the average of those values gives a figure of 52, which means that the average of the reduction in corrosiveness of the 7 samples is 52%.

The Court: You took the average of those because they differed too, the CP acid experiments? A. Oh, they did.

The Court: You took an average on those? A. Yes, Your Honor. In each case, the sample obtained from the well, the acid sample was tested against a CP acid sample of the same strength.

The Court: But the CP acid of the same strength differs? Take right down in your table I, where you take the first line, blank A, so and so, you come over there. A. Yes, the blanks, the concentration of the CP acids, were changed to fit the corresponding acid which they were tested against.

The Court: But the loss in weight is a little bit different on those two. I have .0142 difference in one. That isn't very much.

Mr. Lyon: Maybe we could ask this question. I don't think it is out of order, if the witness can tell us, so that we will know something about what order of accuracy these measurements are believed to have. Within what percents or what decimal point are these results reproducible, do you know? A. Well, I think the set of three tests would

come pretty close to giving us that answer. No two pieces of iron are going to be exactly the same, so that the results will not be identical, but in the first set of values, for example, with the sample 8, Stella Wilcox, the loss in weight of the very first sample was 0.2914 grams; of the second sample 0.2911 grams, which means in that case the two losses in weight checked to within three ten-thousandths of a gram, which is most surprising. But in the third series, the loss in weight was .2854, which is somewhat larger than the other two. So I think that that will indicate pretty well the type of variation to be expected with different samples of the same liquids, but with different samples of iron.

The Court: This question will probably show where I have missed something, or my ignorance, or something. I want you to show this so you can set me right. Now I am looking at Table I, Series D. Then take the very first line, sample 8 Stella Wilcox. Now, that is followed by 3 there, and as I understand it, so far as you know, those three samples are out of the very same liquid. You only ran it to check your test, for safety in your test rather than to find out whether it was different, because you started in with the knowledge that those samples of acid were exactly alike, as I understand. A. As a matter of fact, Your Honor, we took out of the same bottle the material which we diluted and we used identical solution for the three different tests.

The Court: As I understand the running of those three tests was to avoid making a mistake, and they did come out near enough alike so you were satisfied you hadn't made a mistake, isn't that the right theory? A. Yes.

The Court: In other words, the only thing there was that could be any different was in the iron, and probably in cutting out the iron there would be a little difference there? A. Well, yes, Your Honor, but not a difference in size, but probably the composition of the two pieces of iron.

The Court: Even though they were cut out of the same strip? A. Even though they were cut out of the same strip there would be some little difference.

The Court: I say, if there is any difference, it was not in the acid, but it was in the sample that you were treating, is that right? A. That is right.

The Court: The same thing applies when we come down to the blanks that you have? A. That is right.

Q. Your acid was just alike? A. Exactly the same.

Q. As I say, you got three pieces of iron as nearly alike as you could get them? A. That is right.

Q. But any difference there was there in that result probably comes from a difference in the iron, is that right? A. That is right.

The Court: Now do I understand you to say that you have compared for certain figures, taking the initial weight and the final weight, and loss in weight, and percentage of loss in weight and so forth—do I understand that you have compared a certain one in that first group with a certain one in the second group? A. No, Your Honor. We have taken the average of all three in the first group and compared them with the average of the second group.

The Court: You made no comparison of each one? A. No comparison of each one. We simply compared the average of those in the first group with those in the second group.

The Court: Because there was no reason for picking out the first one here and the first one there and comparing them, is that right? A. No, there would be no point in picking those out and comparing them in that way.

The Court: All right. I have followed you.

By Mr. Owen:

Q. Turning now to PX-155, which is your Table II, can you state the average reduction in corrosiveness of all of the tests shown on that sheet, comparing the tests of the defendant's acids with those of the C. P. acid? A. Calculating the per cent reduction in corrosiveness for each of the sets of defendant's acid against the blank and then taking the average of each of those values gives us for the seven samples an average value of 30 per cent. And table III, by similar calculation, gives an average for the seven

samples of 38 per cent. Table IV shows for similar calculations a value of 48 per cent. Now, if you want to go further than that and take an average of all those averages you have a value of 42 per cent.

The Court: What do you do, just add them together and divide by 4? A. That is right, Your Honor.

The Court: Have you got the same number of experiments on each sheet? A. Just about.

The Court: If you haven't, you wouldn't be just right to do it that way? A. No.

By Mr. Owen:

Q. Doctor, I had on my preliminary chart a figure of 49 per cent for the average reduction in corrosiveness in connection with your Table IV and you gave it as 48 per cent. I have just had Mr. Cardwell check it, and he informs me that 49 per cent is correct. Would you mind checking it to be sure? A. I am not surprised, because I made a hurried check of that in pencil a short time ago.

The Court: What would you do, add them together and divide by 10?

Mr. Owen: Yes.

The Court: We ought to be able to do that all right. We might make a mistake about the other. A. Well, the difference is apparently that I took an average of seven samples, and perhaps the average just calculated was for the ten samples.

Mr. Allen Owen: While there are ten figures appearing in this last column, Your Honor, the 4th, 7th and 10th figures are averages of the ones immediately above them, so it would not be fair to add all of them. You should add figures Nos. 1, 2, 3, 4, 6, 8 and 9 and divide by 7 in order to get the proper average percentage reduction in corrosiveness.

The Court: I think we will all agree to that.

The Court: And you have got to treat averages with great care. We will suppose that we average the percentage of colored people in Bay City with the percentage of colored people in Detroit, add the two together and di-

vide by two. You get a very bad result. One is so great that Bay City doesn't cut much figure, yet you are giving it an equal ranking. Maybe that does not enter in here, but I am suspicious that it does somewhere. Do you still stick to your figures? A. Well, Your Honor, I perhaps was inclined to leave the number low and not use the highest figure possible. It is between 48 and 49. It is a little closer to 49 than 48, so perhaps we should call it 49. I think we would be justified in calling it 49.

The Court: Does that mean in English and in figures that this that the Dow was using on that first group right there, we will say the amount of corrosiveness was 47 per cent of what the acid without any inhibitor would be? A. Yes, Your Honor. Or referring to the graph on the chart the C. P. acid gave a certain corrosiveness.

The Court: Well, but which is the amount it ate up? A. The amount it ate up, yes, Your Honor. And with the acid sample referred to, Sample 8, the corrosiveness was really 53 per cent of that of the C.P. acid. Or the reduction in corrosiveness over the C.P. acid was this value of 47 per cent.

The Court: Well, is this your contention as a result of that, that no matter what the shape is, no matter what the size is, if you use those two kinds of acids, this kind which the defendant uses will eat 47 per cent as much as the pure acid? A. Not 47 per cent as much. It will eat 47 per cent less of the iron than will the C.P. acid.

The Court: It reduces it 47. A. That is right.

The Court: To put it the other way, it will eat 53 per cent as much. A. Yes, Your Honor, with that particular iron.

The Court: No matter what the shape is? No matter what the weight is? But it has got to be left sixteen hours. A. I believe that to be true. Provided the ratio of the surface area to the amount of solution were the same.

The Court: I want it to happen the same in each case, that is, exactly the same size, of this kind of iron that you have, exactly that kind of iron, but I thought if you were

right in your argument, that no matter what the shape was, no matter what the quantity was, that if you put the same quantity and the same kind into each, the same shape in each, and left them there for 16 hours, of this kind of iron, mind you, that it was your conclusion that the defedant's acid would eat 53 times as much as the pure acid? A. Your Honor, unfortunately that does not happen to be quite the fact, as we have discovered.

The Court: I thought you were claiming that much for it. Now, you do not claim that much for it? A. I cannot claim quite that much for it.

The Court: Well, all right. What is it that you do not claim to be the fact? A. I must face this fact, that by altering the area exposed as compared to the volume of the acid medium, that that fact, the relation of the area to the volume of acid medium will make a difference. That is difficult to see why at this point, but we will have to face that fact.

The Court: A different iron might make a difference? A. Yes.

The Court: But here you have got two different kinds of strength? A. Yes.

The Court: Say, two men of different strength, one might be able to do a lot more than the other one could do, one might take quite a lot on, and the other take a little, but we can figure out their percentages as to their strength; on other kinds of work you can figure out very accurately the percentage of strength? A. Yes.

The Court: I knew that you did not make any claim that with different kinds of iron your result would be uniform? A. I have found, Your Honor, that I cannot even make the claim that you suggest, at first I thought I might be able to.

The Court: I am glad to know it, because I thought— A. And that will come out later.

The Court: Then what good do these percentages? What do they prove? A. They will show, with the experiment run under these conditions, that the C. P. acid is

more active than the sample acids. Now, if I had been fortunate enough, or wise enough to have selected different conditions in the first part of my experiments, I might have obtained results that would have been even more outstanding. I feel that the results that I am presenting to you at this time represent about the minimum of differences as it has worked out, but I did not know it when I ran these experiments.

The Court: Does whether it was under pressure or not make any difference? A. It might make some difference.

Mr. Lyon: What about temperature? A. It might make some difference.

Mr. Lyon: It does, doesn't it? A. I would expect it to. Some difference.

The Court: You mean the ratio would be different? A. Possibly. Yes, the difference in the ratio would be different.

The Court: There are some things we know. We have different kinds of iron in these two here and you have proven with a different kind of iron the ratio between the two acids varies. A. It varies, yes, it does. But in every case tested with all these different samples, the acid well samples showed less reactivity than the samples of the CP acid. That much we certainly have shown.

The Court: Then all this simply has to do with inhibition? A. Inhibition, yes.

By Mr. Owen:

Q. It is in evidence that there were delivered to you samples of hydrochloric acid taken from the wooden storage tanks of the Halliburton Oil Well Cementing Company at Mt. Pleasant. Those samples were marked N14-B, S14-B, N17-B, S17-B. Do you recall having received those samples? A. Yes, we received those samples, and I might mention that in all our records the samples marked N17-B and S17-B will be referred to as S20-B and N20-B. When the samples were delivered, as I recall, I was requested by Mr. Conner to use that notation and for the moment I don't recall why.

Mr. Owen: That explanation is in the depositions that have been filed, Your Honor. Mr. Conner explained that when this sample was taken, the N17B and the S17B—that means the North and South storage tanks of the Halliburton Company at Mt. Pleasant—he marked them with the 17 N and S series, and when he later examined his list of samples he found that he already had a 17. So he requested Dr. Bartell to change the markings on these samples to N20B and S20B, but Dr. Bartell states that he did not change them on the samples themselves but that in referring to them in his testimony he will use the 20 figure instead of the 17.

Mr. Lyon: Before we start in with any tests on commercial acid, I want to raise a question regarding the proofs, because tests on commercial acid, as compared with the well acid, would not have any significance here. It would be necessary that the well acid and the commercial acid correspond to each other; in other words, that the well acid be that commercial acid after it has been in the tank and been acted on by the lead plate and the current.

We are not satisfied with the proof in this case, and want to raise an objection, that the commercial acid that they are relying on here is the commercial acid that was used in wells on which they have the samples from the well acid.

I would like to call Your Honor's attention to this fact, that the Stella Wilcox well, which the witness has samples of well acid, was treated on August 5, 1938; the Zahn well was treated on August 19, 1938; and the Crawford well was treated on September 10, 1938, as shown by the records, PX-18.

The testimony as to when the sample of commercial acid was taken from the storage tanks in Mt. Pleasant is in the depositions which were received here, but not read. The samples were taken by two of the plaintiff's employees, and the first one is a Mr. Forsman, who in his deposition states the samples were taken on the 18th of August and he says on page 113, "We immediately identified the sam-

ples as to which tank they were obtained from, and they were delivered to the Dow Chemical Company at Midland, Michigan, to Don Conner."

The other witness who assisted in taking the samples was the witness Day, who testifies at page 106 of his deposition as follows: "Q. Well, is it your testimony whatever samples you took from these tanks you brought over here, delivered them to me, Mr. Conner? A. Yes, sir."

"Q. When you delivered these samples over to Midland to Mr. Conner, was Warner Forsman with you or not? A. Yes, sir, both times."

Mr. Conner: If Your Honor please, that refers to samples taken on two different occasions, August 18th and December 6th.

Mr. Lyon: And Mr. Conner on page 134 of his deposition states:

"I requested of Mr. Day and Mr. Forsman some time in August, they obtain samples from the wooden storage tanks of Halliburton which I was told had acid in them, located on North Franklin Street in Mt. Pleasant, Michigan, on August 18th. I marked that date very clearly because it was the day before the Zahn well was treated, I think. On August 19th Day and Forsman brought to me in the Midland office of the Dow Chemical Company, two bottles containing a liquid which they said was hydrochloric acid, each bottle had attached to it a sticker."

Mr. Conner, as I understand it, admits he was in error on that, because Mr. Babcock has showed him that he was in Oklahoma taking depositions at that time, and there is some mistake here, but the samples were taken some time by the light of the moon, and the Halliburton Company has no way of checking. But, obviously, it seems to me they were not the samples of the acid which was taken out of those tanks and taken out to the wells and used in the treatment of the wells, and it would become very significant in this case, I think, whether there is any,—in connection with any comparisons of the condition of the acid at the well and as it was in the storage tanks, whether we are comparing

the right acids, and there seems to be some difficulty here, at least one of these wells treated on August 5th, and obviously that is a different acid from the one they are supposed to have obtained samples of the commercial acid, and another one on September 10th, which is obviously a different one, and the only one could be August 19th, and as to that, why, there is this discrepancy in the testimony, which, I think, needs some explanation before we accept it and go into a lot of proofs as to an exact comparison here which they are going to base an argument. If the samples are not correct, why, we shouldn't start with those proofs.

Mr. Owen: In answer to the statement made by counsel, I will say that there was a discrepancy in the testimony regarding the date at which one of these storage samples was delivered to the Dow Chemical Company and as to the person to whom it was delivered. Altogether, I think Mr. Conner or the witnesses secured some 12 or 15 samples and most of them were delivered to Mr. Conner, at least a good many of them were, and when he testified regarding the delivery of this particular sample he was in error and he admitted it later, and if there is any doubt about the genuineness of these samples, we will clear it up, Your Honor.

The Court: Well, I will treat that as an objection so you can save your record, and I will overrule it. That gives you your exception. But I will hear this proof. I will see. Have you made any experiment with the commercial hydrocloric acid? A. We have, Your Honor.

The Court: So you have got those figures, too? A. Yes, we have.

The Court: Well, wouldn't that help some?

Mr. Lyon: Well, the trouble is, if they are going to compare it with the acid at the well, it should be the commercial acid that was taken out to the well.

The Court: Well, this won't harm us.

Mr. Lyon: It won't hurt us.

The Court: But they say they have got the commercial acid, now.

Mr. Lyon: Well, commercial acid differs, lots of hydrochloric acid differs, as we expect to show, as much as any figures that they are relying on in this case.

The Court: Well, I noticed that the differences weren't an awful lot here, but chemistry deals with pretty small things.

Mr. Owen: I am satisfied we can meet that criticism, Your Honor.

By Mr. Owen:

Q. When you gave the average of reduction in corrosiveness of all of the defendant's acids on your Tables I, II, III and IV (PX-154 to 157), objection was made that they were averages of averages, and without asking you to do it now, I will ask you to make up a new average and be prepared to state what that is tomorrow, basing your average on each individual test and eliminating the averages which are shown in the last column of your several tables.

Q. Now, referring to the samples of defendant's storage acid which were marked N14B, S14B, N17B and S17B, which you received, it being understood that you will use the number N20B and S20B instead of N17B and S17B, will you state whether you made corrosion tests of those storage samples? A. We did make corrosion tests with those storage samples.

The witness produced two tables marked VII and VIII which were offered and received as PX-158 and PX-159.

The Witness: Table PX-158 shows the results of tests with metal strips of strap iron of the same size as used in the first experiments previously described with solutions which were not agitated, and the experiments were carried out at a temperature of 85 degrees Fahrenheit as the previous ones, the volume of the acid solution used being 50 c.c. The time of the test was 16 hours. In other words, all factors relating to the test were essentially the same as in the previous experiments, other than that of the acid samples used. The acid samples referred to as N14B, S14B, N20B and S20B were found to be of concentrated hydrochloric acid of approximately thirty per cent concentration.

The Court: Well, now what about the Wilcox? I have three on that. Now, Table II is the same?

Mr. Owen: Yes, Your Honor. That information applies to all exhibits.

The Court: And Table III is the same?

Mr. Owen (Interposing): As Table IV.

The Court: And so are II and IV?

Mr. Owen: Yes.

The Court: Where do I get that first sample N14B? Where was that from?

Mr. Owen: That was from the North storage tank of the defendant at Mt. Pleasant, and it was taken on August 18, 1938.

The Court: The day before the sample was taken from the Zahn well.

Mr. Lyon: That is the date I raise my objection to. Witnesses say they gave this sample to Mr. Conner while he was here. On that date Mr. Conner was taking depositions in Oklahoma.

The Court: When did you get this sample S14B?

Mr. Owen: Same as N14B, same dates and facts apply. The N stands for the North Storage tank, and the S for the South Storage tank. They have two wooden storage tanks at Mt. Pleasant.

By Mr. Owen:

Q. Now, will you explain what the data on PX-158 represents? A. I might mention that the acid samples from the storage tanks were of slightly different concentrations. The N14B originally as received was 28.5 hydrochloric acid; and the concentration of the sample labeled S14B was 29.3% hydrochloric acid; N20B was 30.3% and S20B 30.7%. I mention that to show that the acids were of slightly different strengths.

The Court: I don't understand why you didn't use them just as you found them. A. Had I done that, the strength would not have been comparable at all to the strength of the acid received as truck sample acid, which was about 15%, about half this strength.

The Court: That storage tank, in there it is not ready for use then? A. No.

The Court: It is going to be diluted or changed by them? A. It apparently does have to be, yes.

The Court: You changed it to get it as near as you could to the way you thought they would use it? A. Yes, I changed it.

The Court: You are showing there wasn't any inhibitor in this?

Mr. Owen: Very little.

The Court: Let me ask you, Doctor, there is a difference between this chemically pure and commercial hydrochloric? A. There is some difference, yes.

The Court: Is there some, in this commercial is there some inhibitant in that? A. There are materials that inhibit slightly.

The Court: The way they sell it? A. The way they sell it, that is true.

The Court: Do you claim they have a patent so nobody can buy any more hydrochloric acid?

Mr. Owen: Oh, no, we don't complain of their using it in the strength in which they purchase it, and with the inhibiting power that it has.

The Court: All right.

The Witness: This storage tank acid of the strength mentioned was diluted to 14.5 per cent, which was the strength of the acid samples 12 and 12B taken from the Zahn well.

Mr. Lyon: May I ask if the dilutions that are referred to on these tables PX-158 and 159 consisted of nothing but the addition of water to the commercial,—or to the so-called commercial acid taken from the storage tanks? A. That is right. Nothing else was put in except pure water, and a blank of C.P. acid of the same strength was prepared,—"C.P." meaning "chemically pure." For example N14B the initial weight of the metal strip used was 14.5279 grams. The final weight was 14.0619 grams,—loss in weight 0.660 grams, per cent loss 3.21. And, for the same S14B diluted

the same way, the per cent loss in weight of its metal strip was 3.29. For the corresponding tests made with the chemically pure acid of the same strength the per cent loss in weight was 3.46, which means that the sample N14B was 92.8 per cent as corrosive as the C.P. acid, or the reduction in corrosiveness was 7.2 per cent; while the sample S14B showed a corrosiveness which was 95 per cent as great as that of the C. P. acid—95.1 per cent, as a matter of fact, and the reduction in corrosiveness was 4.9 per cent.

The other samples N20B and S20B were diluted to an acid strength of approximately 15 per cent. It happened to be 15.1, which is the per cent concentration of many of the solutions we have used for comparison. The per cent loss in weight of the sample tested with the N20B diluted solution was 3.23 per cent, and the loss in weight of the metal sample treated with S20B was 3.36 per cent, and that of the sample treated with the blank of the same strength as the N20B and S20B was 3.64 per cent, which means that the reduction in corrosiveness of the sample N20B was 11.3 per cent; it was 88.7 per cent as corrosive as the C.P. acid, or showed a reduction in corrosiveness of 11.3 per cent. And the sample S20B showed a corrosive effect 92.3 per cent that of the C.P. acid or showed a reduction in corrosiveness of 7.7 per cent.

Mr. Lyon: Is that the same blank that you have at that point in PX-158? A. It would be the same kind of acid, yes.

Mr. Lyon: I call your attention to the fact that there are three values in per cent loss in weight for that blank, and—on both PX-154 and 158 and the individual values are identically the same, as well as the averages. Doesn't that indicate that they are the same? A. If that is true. Well, in other words, it was the same test. I, hurriedly in looking at these figures, did not happen to catch the corresponding values. The blank 14.5—(after examining documents); Yes, they were the same test.

The Witness: The blank of diluted N14B and S14B, using the C.P. HCl in PX-158 means that I took C.P. hydro-

chloric acid and diluted it to the 14.5 strength, and it so happened that I had already prepared such a blank which appears on PX-154 in the fourth series of tests, which read "Blank 12-B (C. P. HCl)," and I used that blank and the tests with that blank in computing or making up the table PX-158. The same blank acid was used in testing against Sample 12B as was used in testing against Sample N14B and S14B, and the solutions were all made up to the same acid strength.

The Court: Doctor, let me call this observation to your attention and see whether I am correct in my interpretation, and, if I am, whether it means anything at all. As I interpret your figures in PX-158, by looking at your loss in weight in grams column and then over cross-wise I am going to compare sample S14B diluted to 14.5 with the second one in the blanks, which is the blank diluted—I don't know if I do understand. I understood your blank to be your chemically pure hydrochloric acid. A. That is right, Your Honor.

The Court: Well, it doesn't matter which one I take, and I am taking the one to make the most trouble for you, which is the second one there. A. All right.

The Court: Now, that is diluted to the same 14.5. Now, I compare over in this loss in weight, in grams, the two, and I gather there that the only difference is .0091. A. Yes; that is correct.

The Court: Well, that is mighty little, isn't it? A. It is.

The Court: Now, I go right down to the 4th and 5th in the column, which are supposed to be identically alike, as near as we can get them, and I find a difference of .0512. In other words, I have got more than five times as much difference between your blank samples tested as I have got between one of the defendant's tests and your blank. A. Yes, sir, Your Honor, but this—

The Court: Suppose I was looking here to find out how much this defendant's dope was inhibited, and to determine that it would be perfectly fair, wouldn't it, for one

comparison, to go over to column 5, the loss in weight in grams, and take the second figure in that column and compare it with the fourth. Why wouldn't that be fair to see how much they had inhibited it?

Mr. Owen: Well, I think that in tests of this kind, Your Honor, it is impossible to have them exactly accurate, and that is the reason, there is a necessary variation.

The Court: But I say, if I was going to only run one test on each, that might be the one that would have been run.

Mr. Owen: Yes.

The Court: I understand you ran more for the purpose of getting the average.

Mr. Owen: Surely.

The Court: And checking yourself. But I am taking only one of those, and I am taking the lowest one and their highest one for the purpose, as I said, to trouble the doctor and make it just as tough as I could for him, you see.

Mr. Owen: If we had done that, we could have made a much better picture.

The Court: Yes, you could have. But I am taking the worst picture you can. I mean, maybe I studied it longer, I suppose, but there is one comparison, that all they would have inhibited it would have been .0091 grams.

The Court: In other words, if you had found the difference between Dow's and yours—

Witness (interrupting): Your Honor, may I remark that I don't believe the contention is that inhibitor has been put in this acid; that if they do not check, why it is just because there happens to be something in the acid that would cause them to be that different.

The Court: If you carried out into your seventh column (of PX-158) the difference between the fourth set of figures and the fifth, what will you get to put in the seventh column? 3.38, one is base, and one is something else—3.60, and what do we get for the seventh column?

(Witness made calculations, slide rule and mathematical)

A. For that particular combination requested and double checked, that would be about 6.1%.

The Court: Well, now, in other words, that means that if we were making this test and the one in the fourth place has been the defendant's, it isn't—it's one of your blanks, chemically pure—but if that had been one of the defendant's and the one in the fifth place had been run just as it was, we could argue from it that there was 6.1%—six and one-tenth per cent inhibitor in it. A. It could be argued that way.

The Court: That shows the argument that could be made and how careful we have to be here. We know there wasn't any inhibitor in it. We know your two acids were just alike. A. That shows why we have to run a number of tests.

The Court: And I don't know how many we would have to run. We are satisfied those two are absolutely chemically pure, each of them 14.5% hydrochloric acid, and we run them, and there is 6.1% difference in their corrosive action. Now, there isn't, as a matter of fact, any difference at all. A. Shouldn't be.

The Court: And the difference all comes by the difference in that iron in some way. A. That is true.

The Witness: I have pointed out that based upon the tests in PX-158 the sample N14B showed a reduction in corrosiveness of 7.2 per cent; S14B of 4.19 per cent; N20B of 11.3 per cent, and S20B, of 7.7 per cent.

PX-159 shows essentially the same type of results for the same type of tests as are shown in PX-158, the difference being that instead of using the strap iron as the iron pieces, strips were cut from National Supply Company's pipe of the size indicated, 1 by 7/8ths by 3/16ths, and the experiments were run exactly as were the experiments with the strap iron. For acid in these tests we had the samples N14B, S14B, N20B and S20B, which we have just discussed, together with the blanks corresponding to these diluted acid samples. In other words, the concentrations of the acids were exactly the same as the concentrations used in PX-158.

This is the National Supply pipe, and that is shown on Table II, PX-155. Referring to Sample 12B of Table II, the strength of the acid used there was 14.5, the same as we used in the tests for Table VIII.

The Court: But, over in Table II you had 14.8. Then you got down to the bottom and it says 15.1, and 15.2. You had a stronger solution of acid in Table II than you did in Table VIII. A. In some instances we did, slightly stronger acid, because the strength of the acid in the truck samples was a little greater for the samples taken from Stella Wilcox than from the Zahn well.

Mr. Owen: I think, Your Honor, you are overlooking the fact that the strength of the blanks was the same as the strength of the defendant's samples which were tested, so that those are the two that are compared in this Table II. You see where the strength of the Crawford acid was 15.2, the strength of the blank was also 15.2.

The Court: But, why was the loss in weight? When I am talking about loss in weight by defendant's acid and the loss in weight by chemically pure acid, I am not comparing one with the other. I was here considering loss in weight one with the other. Now, the size would have something to do with that? A. The loss in weight is not great; the sample N14B, 2.34 per cent, while with the blank, 2.53 per cent.

Mr. Owen: I think if Your Honor will keep this in mind it may help to understand these tables, that in every instance the comparison is made between a C. P. blank of the same strength as the defendant's acid which is being compared with it, so that you cannot say that that is not a fair comparison.

The Court: Do they say they have any of this lead metal electrical current in the storage tank?

Mr. Owen: No. That is a wooden tank.

By Mr. Owen:

Q. Now, did you also compare the storage, the defendant's storage tank samples, Nos. 14 and 20, with samples of commercial hydrochloric acids to see how their

corrosiveness compared? A. We did. We obtained commercial acids by purchasing directly from the different companies, ourselves. Lots of acid from the Detroit Chemical Works, from DuPont, from the General Chemical Company, from the Pennsylvania Salt Manufacturing Company, and from the Southern Acid & Sulphur Company.

Q. Have you prepared a table showing the results of those tests? A. I have for my own notes. I have no other table prepared. The tests were made with each of these acids diluted to a strength of 15.1 per cent hydrochloric acid. The metal used was from strap iron of the same lot as Series A previously referred to. Tests were made in vessels of the same size and the same size strips were suspended in 50 c.c. of acid as before, for sixteen hours at 85 degrees Fahrenheit, and in containers of the same size and shape. And the results obtained expressed in the same units that I have been expressing the other values in terms of reduction in corrosiveness.

The Court: You have got the other figures that lead up to those, so that if they want to see them they can, I suppose. A. I can get any other figures leading up to those, yes. I have them with me in town.

For strap iron, first, I will give the results with Detroit Chemical Works acid. That acid compared to the same strength of C. P. hydrochloric acid showed a reduction in corrosiveness of 15.0 per cent compared with C. P. acid. The DuPont acid with the strap iron, 3.7 per cent. The acid from the General Chemical Company 1.6; The Pennsylvania Salt Manufacturing Company, 0.5 and the Southern Acid & Sulphur Company acid 0.3. In other words, that showed practically the reactivity of the same order of magnitude as the C. P. acids. Now, the average reduction in corrosiveness, taking the average of those five values, would be 4.2, or the average corrosiveness was approximately 96 per cent that of the C. P. acid.

The Court: Well, there you go. As between the Detroit Chemical Works and Southern Acid & Sulphur Company, The Detroit Chemical has got fifty times as much as

the other of that inhibitor in it. A. It has relatively that much more inhibiting action, that is true.

The Court: And if anybody could step up from the other fifty times, they would have too much. Like the fellow who was asked if his brother-in-law was fifty per cent dependent on him, and he says a hundred and ten per cent. A. I have corresponding results with other metal strips, if they are wished.

The Court: That would be interesting. Now, this is all in the strap iron where we have such wide variances, except in the acid? A. Yes.

By Mr. Owen: You might as well give them, then, while you are on the subject? A. I thought it might be of interest to compare these results with those of the National Supply Company material, since we have already done that with the other series of acids. Using the small metal strips, of the same size as I have previously described, and using the National Supply Company pipe and the same acids as used with the strap iron tests, diluted to 15.1 per cent,—

The Court: Oh, you go right on down through, only with another kind of iron? A. With another kind of iron,—

The Court: What is the next kind of iron? A. The National Supply Company's pipe. I am taking the acids in the same order. The Detroit Chemical Works acid, a value of 12.2. DuPont, a value of 6.1. General Chemical Company, 5.4. Pennsylvania Salt Manufacturing Company, 0.7. Southern Acid and Sulphur Company, 0.7. The average of those values is 5.0.

The Court: Here is what surprises me now. The strap iron, the only difference between the strap iron and the National Supply Company pipe, when you use the Detroit Chemical, is just a difference of between 15 and 12.2, which is only 20 per cent.

Mr. Lyon: But it goes down.

The Court: And I come on down here to the next one, and I use the National Supply Company iron with DuPont, and here I get twice as much as I do when I use the other.

I just cannot get it through my head. It does not seem to work. A. Of course, in the latter case it is twice as much, the matter of three units only, 3 per cent out of 100 per cent.

The Court: In one it is twice as much, when I use the National Supply I get twice as much depletion with that one kind of acid, and with the Detroit I get 80 per cent as much. A. That is true.

The Court: I would think at least they would run the same way. A. It leaves considerable room for speculation. It just might be, of course, the inhibitor in the two cases are not the same, and it doesn't function in exactly the same way with the two types of iron. That would be one possible explanation. The impurities in the acid may be different.

The Court: But I don't get much satisfaction in taking an average on a thing that works that way. A. The average in that case is probably not as significant as the other type of averages we have taken of the average of a series of tests. That is significant. Here we have involved another factor—the fact that the composition of these acids, so far as impurities are concerned, are unknown to us. They may not be the same.

The Court: Well, let's get some more irons in here and see where we come out. You have some more. How many have you got there? A. Two.

The Court: All right. I think I will go for them. A. And they leave greater room for speculation.

The Court: And what are the other two? A. The third iron is from the Oil Well Supply Company's pipe and the fourth one from the Atha Supply Company's pipe. Oil Well Supply Company's pipe with the Detroit Chemical Works acid, the first one mentioned previously, 1.3; DuPont 3.5; General Chemical Company 0.2; Pennsylvania Salt Manufacturing Company 0.6; Southern Acid and Sulphur Company 0.2. Those results admittedly are quite different from the other results. With the Atha, Detroit Chemical Works acid 18.4; DuPont 12.0; General Chemical

Company 9.1; Pennsylvania Salt Manufacturing Company 3.5; Southern Acid and Sulphur Company, 9.4, showing distinctly that the different metals react quite differently with the constituents of the different acids.

The Court: I thought I could get down to the bottom there. When you came to the last one it jumps up 9.4. A. We simply took them as we found them.

The Court: If you could work something out of that—

Mr. Owen: I think Your Honor will find that these reductions in corrosiveness with these commercial acids with the exception of this one Detroit sample (and what is in that sample we don't know) but with that exception the reduction in corrosiveness as compared with the chemically pure acids seemed to run along in what the scientists call the same order of magnitude. They are not exactly the same but none of them is high enough to be any great amount of help in an oil well tubing.

Mr. Lyon: I understand that the plaintiff wouldn't charge infringement if any of these acids that have been referred to by the witness were employed as regular commercial hydrochloric acid with no addition of any other inhibitor. That is, DuPont acid or any of the ones the witness has referred to, is that correct?

Mr. Owen: I wouldn't say that, no.

The Court: You depend an awful lot on what you made your fight on.

Mr. Lyon: A fellow would have a hard time knowing on what he infringed.

Mr. Owen: I would say in answer to the inquiry that if the defendant or any other company which is acidizing oil wells for the purpose of increasing their production learned of a certain acid which contained impurities which were of a high order of magnitude and he selected that acid specifically for the purpose of getting the benefit of the Grebe-Sanford invention, I would say he probably would be held, or should be held, as an infringer.

Mr. Lyon: But if he did the same thing, used the same acid, he wouldn't be an infringer?

Mr. Owen: Well, that is a moot question. I don't think it is involved here, and I don't think I am required to speculate on what we might do under those conditions, but what we are complaining about here is something that this defendant has done deliberately.

The Court: Well, it would take 47 times difference if they were going to use,—what is that, Southern, is that, acid? A. Southern Acid & Sulphur Company.

The Court: If they are going to use Southern Acid & Sulphur Company acid it would take 47 times difference whether you bought your pipe of the oil WXC, whatever that is,—if one digs into it, you have .2, and the other 9.4. If I am right 1/47 times as much as the other. So, there is as much as you got in your figures difference than the kind of pipe they used with regular commercial acid.

Mr. Owen: That is true.

The Court: That is as much inhibition as you are suing them for.

Mr. Conner: No, it is not.

The Court: 47. That is what you claim here, 47.

Mr. Owen: No. We are showing that they are doing something to their acid that substantially increases its inhibitive power.

The Court: 47 per cent.

Mr. Owen: No. We don't say that they add 47 per cent of inhibition or of inhibitor to their acid, but we say that when their acids are delivered at the oil well and are used to acidize that well, that they are substantially inhibited within the scope of the Grebe-Sanford patent, and that that inhibition is due to something which they have done deliberately, and which has occurred between the time they placed their acid in their truck tanks and the time they delivered it from the truck tanks into the well.

Now, the question for Your Honor to determine ultimately is whether the amount of inhibition which they have deliberately and intentionally placed in that acid constitutes an infringement of this patent.

The Court: Well, of course, no matter whether they

put it in intentionally or whether they intentionally bought some already in, now that I find this out about this, I would go and buy some of this pipe made by the Southern—no, acid made by this,—I can take the combination in there and get something pretty good, or buy the right kind of acid and right kind of pipes to put in there and I would be pretty well fixed.

Mr. Allen Owen: You would still have a reduction in corrosiveness.

The Court: Of course, I haven't found out yet about that in the pipe, how bad it is and how much I would need, but I think when I get through and get that information it will help.

Mr. Wilber Owen: You could not select your pipe in which you are going to put your acid, that is sure. You might select your acid, if you learned one commercial acid had a high degree of inhibition, but you couldn't select your pipe because you are going to put your acid—

Mr. Lyon: Why not?

Mr. Owen: Because you can't go around the country and say I will only treat wells with certain pipes in. The oil companies use all these different kinds of pipe, and this defendant treats wells equipped with all those different kinds of pipe, and they don't go around and say I will treat a well that has this pipe, but I won't treat one that has a different kind of pipe in.

By Mr. Owen:

Q. Doctor, in your testimony yesterday, you gave the results obtained in corrosion tests of the samples Nos. 5 and 7 from the Stella Wilcox well treatment, Nos. 12 and 12-B from the Zahn well treatment, and two samples numbered 15 from the Crawford well treatment? A. Yes, sir.

Q. Will you state whether or not you consider those samples of acid to contain a relatively small amount of a corrosion inhibitor, as that term is used in the Grebe and Sanford patent, and give your reasons for any opinion that you may express? A. It is my opinion that they do contain a corrosion inhibitor, and that that inhibitor is present

in relatively small amounts. The evidence presented yesterday showed that in each of the tests made, with each of the acid samples from the wells mentioned, that a relatively large reduction in corrosiveness was obtained. By reduction in corrosiveness, I, of course, refer to the fact that these acids gave relatively lesser corrosive action than chemically pure acid, which contains no inhibitor. If one were to obtain the average per cent reduction in corrosiveness represented by the three samples tested from the Stella Wilcox well, for example, on the strap iron, it will be recalled that that value was 44, those samples on the average were 44 per cent less corrosive than the corresponding blank samples of the same strength. The average of the two samples from the Zahn well, the strap iron gave a percentage average reduction in corrosiveness of 45 per cent. The average of the two samples from the Crawford well gave an average reduction in corrosiveness of 70 per cent. It is shown also that substantial reductions in corrosiveness were obtained with each of these acids against similar pieces of metal cut from different oil well pipes. I don't know that it is necessary to repeat my figures of yesterday of the reduction in corrosiveness found, but if one were to take, for example, the average reduction of corrosiveness represented by the Stella Wilcox sample as 44, the Zahn samples average 45, Crawford 70, the average value of those three would be 53. For corresponding acid samples in National Supply Company's pipe, the average of the values would be 31½; of the Oil Well Supply Company's pipe, the average of the values would be 38½; with the Atha Supply Company's pipe, the average of the values would be 51½.

The taking of these average reductions and noting what the average of those values would be in some of the values just mentioned divided by four, for example, would give an average reduction in corrosiveness of 44 per cent which figure, it seems, represents pretty fair value representing the reduction in corrosiveness of these different acids as a group against the different metals taken as a group.

The Court: Where do I find in the patent the language you referred to?

Mr. Owen: It is in a number of claims. For instance, it is in claim 7, "A relatively small amount of a corrosion inhibitor."

The Court: One is enough. Let me see, there was something I was going to ask you about. What do you understand a relatively small amount of corrosion inhibitor refers to? I take it it always refers to at least two things, when you say one thing relative to something you have got that other something always? A. Yes. Well, in connection with this particular patent I would have in mind a value relatively small, meaning something under, say, 5 per cent.

The Court: Well, why? This is for the benefit of the public and the world, and for chemists, probably. Skilled chemists, to help the public.

Mr. Owen: The statement in the patent itself, "The amount of arsenic compound added may be varied, but we have found that from one to five per cent thereof, based upon the weight of the solution, will be satisfactory for the purpose." That is what the patent states about the relative amount.

The Court: But, it is relative to what?

Mr. Owen: Relative to the volume of acid, I understand. A. Yes. That is as I would understand it.

The Court: All right: That is what I thought.

Mr. Lyon (Interposing): Is it relative to the volume of acid, or relative to the weight of solution as stated in Line 87? A. It might be either, and I still would call it relative because it would be not so different from the five per cent.

The Court: Now, my next thought was what would you say when I refer to this commercial acid we have, whether or not that would fit that definition. A. The question being does it appear that the commercial acid contains a relatively small amount of inhibitor? Yes, I am inclined to think it does.

The Court: Does it fit the rest of the definition, "Relatively small amount of a corrosion inhibitor, permitting the acid to act upon the rock formation surrounding the well cavity while applying pressure upon the solution and withdrawing the spent acid"? A. May I have that reference, Your Honor? That is in the body of the patent?

The Court (indicating): I was reading right here. I am asking about what Mr. Owen called my attention to. Claim 7 is what you have. You have it right. A. Yes.

The Court: I was using the claim he called my attention to. The question was, first, whether or not that early description of a relative—containing a relatively small amount of corrosion inhibitor would apply to the commercial acid that you tested, and you said yes, it would. Then I asked whether or not your answer would stand that it applied also to that later part of the claim, in other words, does it apply to— A. (Interposing) Permitting the acid to act upon the rock formation.

The Court: Surrounding the cavity while applying pressure upon the solution and withdrawing the spent acid. A. Yes, Your Honor, I believe it would.

The Court: Well, then, so far as you can see the entire claim reads on and would apply, with your definition, to that commercial acid just as well as it does to the defendant's acid? A. Yes. The only point I would feel that the author of the patent had in mind, an inhibition sufficient to serve for practical purposes, while a slight inhibition might not be sufficient to put the acid in such condition that it would be a practical inhibitor.

The Court: Now, I won't attempt to bother my good friend the Doctor with this further, but I call counsel's attention to the decision in the balloon tire case, wherein they had claims for larger tires, but I never found out and the Court of Appeals never found out how much larger they had to get to get within it, and how small they could get to keep without.

Mr. Owen: Well, I think, Your Honor, that the claim must be read with the purpose of the invention in mind as

it is stated in the specification, and while it is true that these commercial acids could and do contain relatively small amounts of something, we don't know what, different things, perhaps, so that they are slightly less corrosive than chemically pure acid, nevertheless those commercial acids could not be used in a well to obtain the objects sought for and obtained by the Grebe-Sanford invention.

The Court: Well, they never tried it.

Mr. Owen: For this reason: In the first place, the Grebe-Sanford invention gives examples of what they consider to be relatively small amounts of corrosion inhibitor, and it gives one to five per cent. In the second place, one of the objects, as we have already pointed out, of the invention is to insure the delivery of the acid in its, practically its full strength, so that it will operate in the formation. In other words, the object of the invention or one of the results of the invention is to prevent the acid from spending its strength on the pipe or metal with which it comes in contact.

The Court: Has anybody shown me that five per cent will not eat into the pipe?

Mr. Owen: Well, we do know that less than five per cent of a number of the inhibitors mentioned in the Grebe-Sanford patent will give very substantial protection. Right in that connection, I would like to ask the Doctor—

The Court (Interposing): What is substantial protection?

Mr. Owen: Well, substantial protection would be something that would make it commercial, I would say so that it would make it commercially possible to use the commercial acid, in acidizing oil wells, for this purpose, without adding something to it.

The Court: What were those figures I had up there, the first figures for the top column? A. For the strap iron, 15.0 per cent reduction in corrosion.

The Court: Yes, that is what I thought, reduction in corrosion. Well, right over that we get the Atha has a better reduction even than that. You will have to get after

them. You will have to sue them. They are doing a better job than the others.

Mr. Owen: I think Your Honor has a little misconception there. This merely shows what defendant's acids did to the Atha pipe. That doesn't show Atha is using the acids.

Mr. Lyon: Those are not defendant's acids. Those are commercial acids.

The Court: What was it you said?

Mr. Owen: I said that those figures do not show, are not intended to show, what the Atha Supply Company is doing but they are intended to show what the effect of these different samples of acid have on different pipes, and one of them, the Atha, had a higher rate of protection than it did on some of the others, due, perhaps, to some peculiarity of the pipe.

The Court: That is the iron, isn't it?

Mr. Owen: That is the iron.

The Court: Well, all right. On some kinds of iron is the point, the Detroit Chemical Company wouldn't give half the protection that the next one right down below gives.

Mr. Owen: Which table? A. Yes. The DuPont you have in mind.

The Court: And right in my own mind, I am complimenting the Doctor and counsel for plaintiff for putting all these in. That is what I like when we have experiments. I don't like—it makes me a lot of trouble where they will make several experiments—to have them just bring me the ones that prove some particular theory. I like this way of doing it, and I compliment the Doctor for doing these different things and you for letting me know about it. So we can conjure with them in this way. Not only interesting but likely to reach right and true results with these statistics. I can gather statistics, if I do it unfairly to prove almost anything. That is the reason we have to watch it so carefully. On the other hand, I believe in it because we are thorough about it, careful about it, and we do check up on our theories. So not at all in the way of criticism but in

compliment to everyone, I am just calling attention to the fact that I can almost dispute any theory you put up because there are those other ways; the one which I dispute may be unfair, and may be more unfair than the theory you set up, but the situation deals with relative things and you do get pretty near to that tire case. You have to be pretty careful. It pretty nearly has to be (if you are dealing in degrees) it pretty nearly has to be formulas, something of that kind, or the public aren't greatly helped by it.

Mr. Owen: Well, may I say a few words right on that point? That in reading this patent the person skilled in the art who attempts to carry out the invention goes to the specification to ascertain what the claims mean. And if he goes to the specification in this patent he will find not only specific examples or a specific example of how much of an inhibitor to place in a certain amount of acid, but he will also find suggestions that other inhibitors, several other inhibitors, as examples, may be used and he says he has found from 1 to 5% of the inhibitor is satisfactory, and the amount varied perhaps according to the activity of the inhibitor. Now, I am going to show by the Doctor that these ranges of inhibition which he has found to be present in the fendant's samples, are well within the ranges that will result from carrying out the invention by using a number of the inhibitors which the patent names.

The Court: What is the percentage of the lowest one, what percentage of the inhibitor is there?

Mr. Lyon: Your Honor, that is what I would like to know. Do you claim, Mr. Owen, that the defendant's well acid contains 1 to 5 per cent of anything which you call an inhibitor?

Mr. Owen: No.

Mr. Lyon: It does not contain 1/25th of one per cent of anything you call an inhibitor.

Mr. Owen: No, we do not say that it does, but we say that it does contain something that has the inhibitive effect of the materials mentioned in the Grebe and Sanford patent, when used from 1 to 5 per cent.

The Court: Is it anywhere suggested that anything less than 1 per cent could be used?

Mr. Owen: No, but—

The Court: You see, there, you are relying on this relatively small amount.

Mr. Owen: Yes. The claim does not say 1 per cent or less than 1 per cent.

The Court: Then where are we going to start, and where are we going to stop? There isn't any suggestion of a definite amount, it just said "relatively." You see we are getting right back to my balloon tire case, where I said that I never could make any calculation unless I knew—I didn't know when they were bigger—bigger than what?

Mr. Owen: Of course the object, as I stated before, must be kept in mind, and if the patent gives a specific example of what could be used for that purpose—

The Court: No, you see, we get right back to the balloon tire case. You get the balloon tire just as quickly as you get any oversize, and you keep on. But where are you going to start, and where are you going to stop? Here you can get the effect of this just as quick as you get any in, you get some of the effect, and you can keep right on until you get to the point where it will not eat any iron.

Mr. Owen: Yes, you can.

The Court: Well, now, how far down the scale the other way are you going to do it? Just put in a very little, and you help it a very little.

Mr. Owen: I think you have got to go to some practical point which makes it possible to use this hydrochloric acid in an oil well without doing severe damage to the pipes.

The Court: You say the lowest was what per cent?

The Witness: The lowest that I reported, or lowest value expressed in average values of the Stella Wilcox samples, while using strap iron, the value was 44 per cent reduction in corrosiveness; the lowest value I found was with the National Supply Company's pipe which is 25.

Mr. Lyon: That isn't the value the court asked for.

He is asking what per cent by weight of the solution was the inhibitor in there.

The Witness: Oh, I see. No statement has been made as yet as to the inhibitor or the amount of inhibitor.

The Court: Can you tell me what per cent? A. Your Honor, I believe that that is quite likely to be the next thing that counsel had in mind developing, the exact amount.

The Court: You have the figure for it? A. I have the figures and will present it this morning.

Mr. Lyon: It is less than 1/25th of a per cent by weight of a solution, you know that, don't you? A. It may be. I won't say exactly until we get the figures.

The Court: And, you have the figures exactly, so we will get it for this commercial? A. I have the figures, yes, sir, Your Honor.

The Court: That is fine.

Mr. Owen: I want to call attention to one thing before we pass this point, and that is that the claims of the patent do not specify 1 to 5 per cent, and the 1 to 5 per cent is the amount which is recommended in case arsenic is used as the inhibitor. Now—

The Court (Interposing): What we started out with, I was criticizing the patent because it did not give a formula, and you were suggesting that as getting away from that criticism. That is the only way we got into that Michigan. I was saying if this patent doesn't give any formula, what does it do, and where are we going to stop? If you find the least bit in, is it going to be an infringement?

Mr. Owen: I think that the amount, that is the per cent of the inhibitor to the total amount of the acid, is not the important thing but it is the effect. If you can find some other inhibitor by using one-half of one per cent, or a quarter, or one-tenth will be as effective as the 1 to 5 per cent of what the arsenic is, why, then, you are practicing this invention.

The Court: In other words, nowadays since this patent if the natural and economical way of making hydro-

chloric acid gets some of that inhibitor in, since this patent came out they can't use that particular kind to treat the wells, and they could before?

Mr. Owen: No. I think that this patent—

The Court (Interposing): If nature put it in. If you make it. I take it some of these hydrochlorics that they call commercial, that they find that in those it is cheaper than it would be if they had to go and take that out, isn't that true, Doctor? A. That may be the case in some instances. I—

The Court (Interposing): Have you any idea at all with these commercial hydrochloric acids, putting some of that in to treat wells in there, and get better results, or have you got the idea it has always been in there ever since we began to have commercial hydrochloric acid? A. I think my opinion would be that practically all commercial hydrochloric acids have contained some ingredients that might have had some effect, yes.

The Court: That was my idea.

Mr. Owen: I might call attention, Your Honor, to a chemical case I had a number of years ago in which the process was for the manufacture of arsenate of lead, and the claim called for reacting upon lead oxide with arsenic acid in the presence of a catalytic agent. And, the defendant at first infringed by adding a catalytic agent to its solution definitely for that purpose. A decree was entered and the defendant then changed its process and discontinued the addition of any catalytic agent to its acid, but in manufacturing its acid it left in certain impurities which acted as this catalytic agent, and our Court of Appeals said that it was preventible. We showed that it was preventible. It didn't need to get that in. It was simply carelessness in the process of manufacture, and the Court of Appeals held that it was an infringement regardless of how it got there.

The Court: Somebody had a patent that makes all the world be careful.

Mr. Owen: That is what every patent does, yes.

The Court: I don't think it makes people careful, for instance, about what I do down on the farm. If I have been

doing it right along, and they get a patent on something, I can keep on doing what I have been doing, surely.

Mr. Owen: Oh, yes, undoubtedly. We can't get a patent that can stop you from doing what you have been doing.

The Court: Supposing back in 1895 when they acidized those wells, do you suppose they had to have absolutely pure stuff?

Mr. Owen: No, I don't think they did.

The Court: But, you can't use that stuff now?

Mr. Owen: Yes, they can. We don't content this patent is entitled to any such construction as that. We don't contend we can prevent anyone from buying commercial acid and using it for treating oil wells to increase their production, unless that acid has been deliberately spiked in order to make it suitable for this purpose, and I say if any acid manufacturer does that—

The Court (Interposing): Does it make a difference? One chap that is careless and makes it, and you cay buy the acid with it in, and another chap is a careful fellow and he puts his up to the same height with care, and you can't buy that acid.

Mr. Owen: No. He wouldn't put it up the same height with care; he would put it up deliberately for that purpose.

The Court: But, you see, the varieties you get in commercial acid. And, if I picked deliberately, I take it, from the bargain counter my acids, and I was going to say my irons, but yet if I was drilling a well, and this patent was around me, why don't I pick my iron I use in my well, and pick the acid, and I can do a pretty good job here by doing these two now.

Mr. Owen: Well, I would say if you pick a commercial acid that is not especially prepared to avoid this patent, why, you would be safe.

The Court: Well, I pick my iron, too. I am going to pick them both. I am going to pick the one that will do the best job, and the other.

Mr. Owen: If you want to do that, we won't object to it.

The Court: I will get as good a job here by doing these pickings, I think, as the defendants.

Mr. Wiles: Oh, no.

The Court: I don't know. If I pick the highest iron and the lowest acids.

Mr. Wiles: No. The best here is 18 per cent, if you got it all, and those fluctuate. The defendants are much higher than that.

The Court: That is 18 what?

Mr. Wiles: 18 per cent reduction. That means it corrodes 82 per cent of the normal corrosion.

The Court: I haven't found out yet the percentage, and you don't say anything about corrosion. You talk about per cent.

Mr. Owen: We talk about reduction in corrosiveness.

The Court: Not in your claim.

Mr. Owen: Oh, no. We don't say anything there. We say, "relatively small amount of corrosion inhibitor."

The Court: I take it that that is talking about percentage, isn't it, where you talk about that amount there; I think that is talking about percentage.

Mr. Owen: I think so, I think that means that you could take an amount that is sufficient to fulfill the purposes of this invention.

The Court: Well, you have an invention then that if I want to have my pipe eaten, for some reason, I do not infringe, but if I do not want to have it eaten, I do. I use the same thing, I put it down there, I have been using it, I have got some lime on my pipe, say, and I want to get that off, so I put it down there, and if it eats off, on the walls of my well, I will get more oil, and if my purpose was to get that off, I have not infringed, but if that was not my purpose, and I knew it, I have infringed. Well, I didn't know that there was even such a law. I know, criminally, we put folks in jail because of their intent, but I didn't know in this patent game that we did that.

Mr. Owen: I don't think we do, Your Honor. I don't think that you would be infringing if you used commercial hydrochloric acid that was not specially prepared and spiked for this purpose to do anything that does not come within the terms of these claims.

The Court: But supposing it had been specially spiked, but I did not know it. I look at these figures, and I see this 18.4 over there, and I say, "That is the boy I want," and I go and buy that. If it has been specially spiked, I infringe. If it has not been specially spiked, I don't infringe.

Mr. Owen: Then I think it would be up to us to stop the manufacture of that acid and the sale of it for that purpose.

The Court: Then my infringement depends on my intent and not on what I do, but what my intent is. Maybe that is the patent law, but I didn't know it.

Mr. Owen: You see, my associate calls my attention to this point which I evidently haven't made clear, that this patent covers the making of the acid less corrosive and that—

The Court (interposing): Less corrosive than what?

Mr. Owen: Less corrosive than it was, than it would be under ordinary commercial processes of manufacture. And making it less corrosive for the purpose of using it in making use of this invention. Now, that is what the defendant has done in this case, Your Honor. We will show that the defendant is—we have already shown that the defendant's storage acids are less corrosive than this Detroit sample of commercial acid, but more corrosive than the average of five commercial acids, and we will show that the defendant does not purchase this acid from the Detroit Chemical Company but from other companies, Pennsylvania Salt and General Chemical, whose acids have been or are among the five commercial acids that were analyzed here.

The Court: You are emphasizing this part, the method of increasing the output of an oil well which comprises introducing into the base of such well—then if I put it down

in there and then would apply some electricity and something to it, such that I changed it and let it do its dirty work, I wouldn't infringe, I take it, but if I do it before I put it down into the well, then I infringe. Is that the breadth of this patent? Suppose I shoot this lead and electricity, or whatever it is, down in there after I have got it in there, and then make it work. You claim I infringe then?

Mr. Owen: No, I would say not.

Mr. Conner: All of these samples—

The Court (interposing): I think you want to disagree with him, don't you?

Mr. Conner: No. I just wanted to get this statement over with. All of the samples that plaintiff is relying on to show infringement were obtained out of the truck tanks of defendant on the surface. That is, we obtained samples of the acid on the surface and not of what went into the well, but if we had not obtained the samples that acid would have gone into the well.

The Court: Suppose you made it that way by the container that you carried it in. You claim that infringes just the same?

Mr. Owen: Yes, sir; we do.

The Court: Now, what I was saying, suppose you put it down into the well and then you put your lead down there and you let this dirty work go on.

Mr. Owen: That would not infringe.

The Court: Then you wouldn't infringe?

Mr. Owen: No; it would not.

The Court: All right. Then you have got your patent narrowed down to a point where it is because they do it, they apply this, let it come in contact with lead as it is approaching the well and before it goes down into the well, but if they wait until it is down in there it wouldn't infringe.

Mr. Owen: I think that is true.

The Court: All right.

Mr. Owen: I will tell you why. If you put your acid

down in the well and keep it out of contact with the pipe, you don't need an inhibitor when you get down there, but you need an inhibitor when it goes down through the pipe. And you need it for two purposes. First, to protect your pipe from corrosion or being eaten up. Secondly, to insure the delivery of the full strength of the acid into the formation where it is intended to do its work. Now, if you did what Your Honor says, if you put this acid down into the well without inhibitor in and then added inhibitor when it gets down there, electrically or in some other way, why, you wouldn't be accomplishing the purposes of this invention, because you would be destroying your pipe to get the acid into the well. You would be destroying your pipe and your acid also. You cannot destroy one and not the other.

The Court: Even though it is perfectly good, they would be guilty of contributory infringement every time they hauled a tank load under your patent if they hauled it to a well where they were going to put it down.

Mr. Owen: Yes, they would.

Mr. Conner: This patent, Your Honor, does not cover or stop anybody from using commercial acid. Commercial acid was old—

The Court (interrupting): They could put it down into the well.

Mr. Conner: It had been done before.

The Court: Not that I know of.

Mr. Conner: I think Frasch and Van Dyke did use glass carboys.

The Court: But you agree before you got your patent it would be all right for them to have hauled the commercial acid to the well with a lead tank and pour it down into the well?

Mr. Conner: I see no reason why what you were doing before the patent was taken out couldn't be continued. This is what we do—merely take commercial acid and improve the acid to make it less corrosive than it was before. So you have less danger and trouble with corroding of equipment.

The Court: It doesn't matter how little you do that?

Mr. Conner: Obviously we couldn't claim the infringement existed if the corrosiveness as effected by the alleged infringer is still within the degree of corrosiveness enjoyed by the commercial acid. As the proofs come out we will show defendant's storage acids all enjoy the same degree of corrosiveness, but the acid used in treating these wells is way out of that class.

The Court: But they had already learned to keep their stuff before your patent, this commercial acid with something in it that increased this inhibitor.

Mr. Allen Owen: Not before.

Mr. Wiles: No, sir. That was all gotten up afterwards.

The Court: I say before your patent—

Mr. Wiles: The defendant's patent says take inhibited acid with the inhibitor in it and carry it in a common iron barrel. Now, that isn't what the defendant is doing at all. The defendant takes presumably uninhibited commercial acid, then puts it into a special tank that is got up for the purpose, we charge, of adding an inhibitor, the natural corrosion the commercial acid puts upon it. A slick trick for getting a tank fixed up to add the inhibitor mechanically.

Mr. Wilber Owen: There was no delivery of acid in steel tanks before the Grebe-Sanford invention. They used wooden tanks, not only around the plant in Midland but for deliveries outside. You can't show a single instance where a steel tank was used for delivering acid around the country, but after the Grebe-Sanford patent issued it became known—this defendant discovered, at least—that instead of introducing an inhibitor into its acid as it did during the year 1935 it could get that inhibitor in the acid by fixing up an especially prepared tank. So that although the acid wasn't inhibited when it left the storage place, it became inhibited during the passage in transit to the well where the treatment was to be made, and therefore when the well was treated it was treated with inhibited acid.

Now, there is no reason why acid cannot be delivered today as it was before the Grebe-Sanford patent, either in rubber-lined tanks or in wooden tanks, or in carboys, but because the defendant owns a patent on a means of protecting a drum for shipping inhibitors or pickling compounds doesn't give it a right to use that invention in order to create an inhibitor during the transit of its commercial acid to the well. There is nothing of that kind in the Gravell patent. It wasn't intended to do that, and the fact that Grebe-Sanford have a patent on the use of that inhibited acid at the well for a specific purpose should not be limited, I submit, to cover the addition of inhibitors to the acids that are so used. It covers the use of inhibited acid. And when that acid is inhibited, whether inhibited by the addition of substances at the well or at the tank station or in transit, doesn't make any difference in carrying out the Grebe-Sanford process.

The Court: I haven't read that patent yet. What are the claims in that?

Mr. Owen: You want the claims of the Gravell patent?

Mr. Lyon: Claim No. 1 says: "The method of preventing an acid solution from attacking a steel transportation or storage drum containing it which consists in dissolving in the said acid solution a material capable of precipitating a substantial protective coating on steel, and allowing the admixture to contact with the inner steel surface of the drum."

The Court: Now, what did you say about the question of putting it in a pipe line?

Mr. Owen: It does not say anything about putting it in or through a pipe line.

The Court: What do you say as to whether, if they put it in a pipe line there and transport it, or, you do that,—can you do that without infringing?

Mr. Owen: Now that Your Honor has asked that question, we say that the defendant does not protect the well tubing in the manner specified in the Gravell patent; that it protects the well tubing by placing—either by placing an

inhibitor in the acid, or in forming the inhibitor in the acid during the transit from the storage tank to the well.

The Court: What do you say about whether the defendant's patent covers putting an inhibitor in it, we will say the same kind that you do, in order to prevent their tanks from corroding? Does their patent cover that?

Mr. Owen: Their claims are broad enough to cover that. We say that was not new.

The Court: Then if they are that broad, why was the pipe line—if they did use that to transfer some of the stuff around through the pipe line, why wouldn't it be an infringement of their patent if you took—if you put the inhibitor in, the same as you do, and let it run through a pipe, to transfer it around your premises?

Mr. Owen: That claim is directed to the protection of the drum in storing or shipping acid.

Mr. Lyon: It says "transporting."

The Court: What do you think about their patent? I am getting off the track, I know that; this is prior art. What do you think about their patent as to whether or not it clearly covers inhibiting by this method they are following now, or does it also cover not only that method but putting in the inhibitor like you put it in? Is there a patent broad enough to cover both of them?

Mr. Owen: Assuming that their claims are valid, they cover placing an inhibitor in the acid for the purpose of protecting the drums, storage drums and shipping drums.

The Court: Do all these inhibitors inhibit by putting a deposit on the thing they are going to eat so that they can't eat it, so that the acid can't eat it, or is there something in there that just dulls their teeth so they can't bite? Which is it?

Mr. Owen: Both, Your Honor. There are some inhibitors, I believe, that form a protective coating on the surface of the metal, and others that dull the teeth of the acid so it can't bite.

The Court: Doctor, to get back to chemistry here, in the defendant's inhibitor does that put a mask on the girl

so they can't bite her, or does it dull the teeth so that it can't bite her? A. I am not as familiar with the patent referred to as I, perhaps, should be, but from the statements that have just been made it appears that a coating is formed on the metal so the acid does not get to the metal. That seems to be the intent.

The Court: How about the plaintiff's way of doing it? What about that way? What kind of inhibitor is that? Is that a mask or dulling?

Mr. Lyon: The plaintiff uses arsenic, and that is the material or patent in suit we say is the one that does it. They use the very material that is in our patent.

A. To a degree, Your Honor, I feel that it forms a coating, but, furthermore, as it forms a partial coating it sets up a potential in the system such that the acid then cannot so readily react with the iron so that it is stopped in two ways. So, we may say it puts on a coating and also tends to pull the teeth.

The Court: Is that true of the defendant? A. I believe it is.

The Court: Is that true of all of them that you worked with? A. In the case of the inhibitors I think it is quite true.

Mr. Owen: Have you made any tests of the samples Nos. 5, 6, 8, 12, 12B, and 15, with a view to ascertaining what they contain that might cause them to be inhibited? A. I have made such tests and found them to contain small amounts of copper, lead and iron in solution.

Q. Will you explain how you determined that? A. I determined by quantitative analyses the amount of the copper, lead and iron in solution. Specifically, the iron was obtained by the phena-thioline method. The lead was determined by the di-thizone method. The copper was determined by the thio-carbonate method. I have given the percentages of copper, lead and iron which I found in those samples in parts per million by weight. I have the data in tabulated form in Table No. XI.

(The table was offered and received as PX-160.)

Mr. Lyon: What do you mean by parts per million; per million of what? A. Exactly that. Parts per million by weight of the material found in respect to the solution.

(The Witness): The analyses were made on the samples mentioned. Starting with sample No. 5 from the Stella Wilcox well, which contained 14.8 per cent hydrochloric acid, there was found 2.9 parts per million of copper, 410 parts per million of lead and 480 parts per million of iron. From the sample No. 6 from the Stella Wilcox, with the same acid concentration, copper 3.6 parts per million, lead 420 parts per million, iron 470 parts per million. And, in sample No. 8 from Stella Wilcox the copper content was 4.2 parts per million, the lead 420 parts per million, the iron 470 parts per million.

Now, the average metal contents of the samples taken from the Stella Wilcox well, that is samples 5, 6 and 8 were, of copper, 3.6 parts per million, lead 417 parts per million, and iron 473 parts per million.

The Court: Does that mean, your first column 14.8 now isn't in the same terms as the next column? A. No, Your Honor.

The Court: This is the per cent of the solution? A. That just happens to have been the concentration of the acid.

The Court: I understand you analyzed to get this per cent, or did you analyze the whole thing and just say 14.8? A. Well, what would be done would be to take a given mass of solution and then analyze that and calculate how many parts of copper per million parts of the mass of the whole.

Mr. Owen: Now, will you explain the other figures on the Exhibit PX-160? A. Analyzed in a similar fashion, the samples from the Zahn well, sample 12 contained 2.7 parts per million of copper, 410 of lead, and 410 of iron.

Q. Right at this point, Doctor, I am going to ask you to tell the court of the incident you explained to me where merely stirring something with a copper spoon had a decided effect. Will you tell the court what that was? A.

Well, I think presumably the thing I referred to at that time was rubber latex. The rubber latex is often called the milk of rubber, the white fluid material which, if allowed to flow out on a surface, and dry, will become rubbery and elastic, and one can pick it up and stretch it. But, I have done this experiment. I have stirred some of that latex in a beaker with a copper wire for a very short time, and then poured some of that latex on the surface and it would not set, it would remain indefinitely sticky and gummy. And, the use of latex as coatings is often prohibited by the fact that traces of material will greatly alter its properties. That small amount of copper will greatly alter the property of latex.

In the same connection, if I may mention it, speaking of traces of copper, I was curious to see what references I could find with reference to the effect of that. I found this statement which occurred in Alexander's Colloid Chemistry published in 1937, that less than one part per million of copper in coffee can be tasted, which seemed a bit surprising at the time. And then I found another statement to the effect that six-tenths of a part of copper per million are essential before free-swimming oyster larvae will set. Copper must be present, but that small amount, six-tenths of a part per million, is sufficient.

Then I found another statement, how true I do not know, that traces of copper, such, for example, as are found in grandmother's copper preserve kettle, inhibit bacteria and moulds, and minute amounts of copper sulphate have been used to kill troublesome algae, etc., in reservoirs Those were references that I found in some of the chemical literature.

Q. (By Mr. Owen) Doctor, did you also analyze the storage tank samples No. 14 and 20 for their metal content? A. Yes, sir, I did, and have a table showing the results of my analyses.

(The table was offered and received as PX-161.)

The Court: Before you leave this other one, Doctor. Which of those are inhibitors? A. Well, Your Honor, I

have made quite a detailed study of that, and I have a table which I expect I will present shortly showing the effect of these things. It is probably no anticipation to state that the copper is really the bad actor there.

The Court: Of course, iron is not at all? A. Very little, if any.

The Witness: PX-161 gives the analysis of the storage samples. The N14B, to which we have previously referred, full strength, not diluted, showed 1.5 parts per million of copper; 10 parts per million of lead; and 27 parts per million of iron. Corresponding values were obtained for the other samples. S14B showed 1.5 parts per million of copper; 8.7 parts per million of lead; 13 parts per million of iron. Sample N20B, 0.37 parts per million of copper; 5.5 parts per million of lead; 15 parts per million of iron. Sample S20B, 0.56 parts per million of copper; 16 parts per million of lead; 21 parts per million of iron. These are the amounts of those metals which I found in the samples of acid in the strength in which I received them.

I have another table showing the metal content of these same samples, diluted to the strength of the well samples. That is my Table XIII.

(The table was offered and received as PX-162.)

Mr. Owen: PX-161, Your Honor, is before the acid is put in the truck and PX-162 is after it is put in the truck and diluted about 50% with water. The purpose of PX-162 is to enable us to compare the amounts of these metals in the diluted storage samples with those in the truck samples (PX-160), the dilution being the same on both of these exhibits PX-160 and 162.

The Court: Maybe the Doctor can help me a little by some suggestions as to why from one tank he got twice as much copper in it as the other. That is in the tank, is it? A. That is the storage tank, Your Honor.

The Court: Well, in the storage tank what would be the explanation of that? What could be? I hadn't hoped for the best, but what do you guess it might be? A. Unfortunately I haven't an explanation for that. In this case

it is evident copper got in somewhere. The acid may have come in contact with that copper. Where that copper may have been, we have no evidence, so far as I am concerned that would show that.

Mr. Owen: I think, Your Honor, the differences in the amount of copper in the storage samples might and probably did result from the fact that the defendant bought its acid from two different sources, and they had two tanks, so when they would get in a carload from one source they put that, perhaps, in one tank which was run down, and when they get a carload from another source they put it in the other tank.

Mr. Lyon: Those are wooden tanks. I don't see how the copper got into the wood. I don't know.

The Court: Let's see; can I go back to the other formula that you are talking about the acid, where they bought the acid? Can I go back and trace what kind of acid they bought? They must have bought some from one of these, Pennsylvania Salt Company or General Chemical Company.

Mr. Conner: Yes, the third and the fourth acids on the list.

The Court: Yes. I will just look at these and see how they go. Well, on the whole, they are buying about as poor an inhibitor as there is, aren't they? The poorest. They have got the two poorest inhibitors there are, isn't that right? A. Just about, as far as these tests indicate.

Mr. Wiles: That means the poorest, probably, of the commercial acids.

The Witness: The amount of copper found in the average of the two Zahn samples, namely 12 and 12B, was 3.1 p.p.m.

The Court: You are looking at PX-162. A. It happens, Your Honor, that I am referring to something beyond that in my own notes. I have extra copies of these tables, I find, for making the comparison.

(The table was offered and received as PX-163.)

Witness (continuing): On the table to which I am referring now is found the data, analysis data of samples 12

and 12B from the Zahn well, the analysis of N14B diluted to the same strength as the samples from the Zahn well, which was 14.5 per cent, and the analysis of the sample S14B diluted to the same extent. The last two are the storage tank acids, and the first two are the truck tank acids.

Mr. Owen: I might state, Your Honor, that this Zahn well treatment was made on the day following the taking of the N14B and S14B samples.

The Court: Now, then, let me see. I really don't see, so I will think out loud and have you correct me. The 12 Zahn is just as it was taken from the defendant's Zahn truck?

Mr. Owen: Yes, at the well. That is also true of 12B. There were two samples taken at the same time and split, so that 12 and 12B are really parts of the same sample, from the same truck. The N-14-B was taken from the north storage tank and the S-14-B was taken from the south storage tank.

The Court: And after you have taken it, you have diluted it down so it would be the same acid strength as that that you had taken from the truck. A. That is it.

The Court: Now I have the whole picture.

The Witness: It will be noted then that the composition of the first truck tank sample indicated as 12 Zahn contained 2.7 parts per million of copper, 410 parts per million of lead, and 410 parts per million of iron. The other sample, 12B, contained 3.5 parts per million of copper, 460 parts per million of lead, and 350 parts per million of iron; or an average of metal contained in these two samples, copper 3.1 parts per million, lead 435 parts per million and iron 380 parts per million.

Of the storage tank samples, N14B contained 0.72 parts per million of copper, 4.8 parts per million of lead and 13 parts per million of iron; while the sample taken from the other storage tank, S14B, and diluted, contained 0.69 parts per million of copper, 4.0 parts per million of lead, 6.0 parts per million of iron; or the average metal content of these

two samples is, of copper 0.70 parts per million, of lead 4.4 parts per million, and of iron 9.5 parts per million.

Now, comparing the values, first of copper, it will be seen that the copper content of the truck tank sample, the average value is four times that of the storage tank sample, approximately four times.

The Court: You mean the quantity, the weight. A. The quantity, that is right, Your Honor. The amount of copper per unit weight is four times as great in that truck tank sample as in the storage tank sample. Of lead there is about ninety-nine times as much in the truck tank samples as in the storage tank samples. And of iron about 40 times as much in the truck tank samples as in the storage tank samples.

The Court: I can work out a theory as to the increase in lead and iron, but I have a lot of trouble about that copper. A. I have had trouble, also, Your Honor.

The Court: You find it quite easy, don't you, to explain why the lead and iron increases? I don't know about the proportions or the amount. A. Yes, Your Honor. After having read the depositions of the structure of the truck tanks, and so on, why, I can understand where the lead might have come from, and the iron. And, there is some copper in the lead which dissolved.

The Court: That may be the answer, then. A. That is, probably, a part of the answer. Whether there is enough lead there—

The Court: It is usual to have some copper in lead? A. It is not uncommon at all, and I have reasons to believe that in this particular lead there is some copper.

The Court: That may be understood, then. If there is a trace of copper in lead, at least for the present I can see how, if the lead is coming off and going over to the iron, and there is some copper in it— A. (interposing) That copper is bound to go in, yes. Such copper as is present will go in.

Mr. Lyon: As I understand it, witness, a trace of

copper is not an uncommon impurity in lead, is that right? A. In commercial leads copper is sometimes found.

The Court: Then you are inclined to think—I will put it this way: have you figured out any better theory now as to how that could happen, than that? A. Well, I haven't figured out a better theory to account for some of the copper, at least.

Referring to my table XIV, PX-163, the last line at the bottom of the page means that there is approximately four times as much copper in the Zahn samples as there was in the diluted 14B samples, and 99 times as much lead and 40 times as much iron.

I made up a similar table showing the relative increases of copper, lead and iron in the Stella Wilcox treating acid as compared with the 14B storage acid.

(The table was offered and received as PX-164.)

The Witness: In this table is given the data showing the amounts of copper, lead and iron in the three samples from the Stella Wilcox well and from the two storage samples labeled N14B and S14B. The Stella Wilcox samples are numbered 4, 6 and 8. Perhaps it would be sufficient to give the average copper, lead and iron content in the Stella Wilcox samples, which would be 3.6 parts per million of copper, 417 parts per million of lead and 473 parts per million of iron.

Q. And how much increase was there in the copper, lead and iron contained in the Stella Wilcox samples over that contained in the 14B storage samples when diluted to 14.5% strength? A. The average metal content of the two storage samples was 0.70 part per million of copper, 4.4 parts per million of lead and 9.5 parts per million of iron.

The Court: Isn't that just the same as in PX-163? You didn't bother to run it again? A. No, Your Honor. Simply we made the one analysis, and a comparison then of the metal content of the Stella Wilcox samples to the storage samples mentioned showed 5 times as much copper in the Stella Wilcox truck samples as in the storage sam-

ples, 95 times as much lead and 50 times as much iron. It will be understood that those figures are approximate, although nearly exactly correct.

I have made a similar table comparing the Crawford samples No. 15 with the storage samples numbers 14 and 20.

(The table was offered and received as PX-165.)

The Witness: That table shows that the average copper content of the two samples 15 from the Crawford well contained 4.8 parts per million of copper, 53 parts per million of lead and 210 parts per million of iron. The average metal content of the four different storage tank samples examined had 0.46 parts per million of copper, 4.7 parts per million of lead and 8.9 parts per million of iron. That is an average of the four storage samples N14B, S14B, N20B and S20B diluted to 14.5 and 15.1% hydrochloric acid, respectively.

Mr. Owen: Now, is it clear, Your Honor, what these tables XIV, XV and XVI show? (PX-163, 164 and 165.)

The Court: I think so.

Mr. Owen: I will ask you, Doctor, have you analyzed any sample of the lead plate which you understood was taken from one of the defendant's truck tanks? A. We have.

Mr. Owen: That is one of the samples that has been covered by the stipulation. Mr. Babcock gave us one of those strips they put down in the tanks when we were taking testimony at Mt. Pleasant.

Mr. Lyon: That wasn't supposed to be necessarily one of the lead strips in these particular trucks. It was one of those they were using—

Mr. Owen: It was given to us as representative of the lead you were using.

Mr. Lyon: Was it one of the lead strips that came out of the tank?

Mr. Babcock: No.

Mr. Lyon: There might be variation, so far as I know, in lead strips. That is the only statement I can make

about it—that he gave you one. Had it been used at all?

Mr. Owen: I think not.

Q. (By Mr. Owen) Now, will you state what you found that lead sample to contain? A. We found the lead sample to contain copper. As to how much I am not sure I have the figures at my finger tips here.

Mr. Owen: Regarding our obtaining of that lead strip, we were taking testimony over at Mr. Pleasant and Mr. Edwards explained to us how they polarized their tanks by putting this lead strip down in the acid and attaching a storage battery to it, running the battery down. I asked him—"Q. Have you any of the lead strips in stock which you use in polarizing a new tank? A. Yes. Q. Here in Mt. Pleasant? A. I think so. Q. Would you furnish us with one of those strips if we pay for it? A. Yes." (Mr. Owen reading from testimony.) And he gave it to us. We went over to their storage warehouse, Mr. Edwards picked it out and gave it to us.

The Court: All right. I will admit the analysis.

Mr. Owen: I will say, Your Honor, I don't concede that the burden is on us to account for the presence of these metals in their treating acids. We found them there and we are giving Your Honor the benefit of what we found and of any possible explanation we can offer, but it is not a burden that we must sustain to show how they got there.

Q. (By Mr. Owen) Now, Doctor, you heard what I stated to the court about the possible sources of this copper but Mr. Wiles calls my attention to the fact that that is not testimony. Will you state where you think it might have come from?

Mr. Lyon: If the Doctor said he doesn't know, I don't see why we should have guesses. If they are relying on this copper as being what the defendant added, it seems to me if anybody is going to furnish evidence on that, he should lay a foundation as to knowing something about it. I don't understand the Doctor has ever seen the defendant's system or examined it. I don't even know what explanation he has had of it.

The Court: I will let him answer it.

A. Well, as I stated this morning, if lead contains copper, that copper will go in solution and we know that it is highly probable that the lead used contains some copper. That copper will go in solution. Now, if there is more copper in the solution than can be accounted for by the lead used, it must come from somewhere. The only obvious source would be from the equipment. Just how the tanks are put together, whether by chance there is brazing in the tank—as it seems to me I heard that word used yesterday—it would imply brass somewhere. I can't quite believe the tanks would be brazed. I am not suggesting that, unless perchance the tanks are brazed. The tanks may have some copper fittings; there may be valves or there may be copper in the pumps somewhere for transport of the acid, through which the acid would pass and pick up some copper. In other words, it appears the copper must come from some of the equipment, from somewhere. Not being entirely familiar with the equipment, it would be mere speculation to say where it does come from.

Q. Mr. Owens: It is in evidence that samples of Mt. Pleasant tap water were delivered to you. Do you recall having received them? A. I do.

Q. And, did you analyze them? A. I did.

Q. Could the copper in the defendant's treating acids used at the Stella Wilcox, Zahn, and Crawford wells have come from the Mt. Pleasant water used to dilute the storage acid? A. No. The copper content of the water was less than two hundredths of one part per million.

Q. Now, Doctor, have you conducted any tests to ascertain what, if any, effect the presence of small amounts of lead and iron and copper, or either of them, in approximately 15 per cent hydrochloric acid solutions has on the corrosive effect of the acid on iron or steel? A. We have conducted a fairly extensive series of tests of that type, tests in which small pieces of iron of the size previously described, strap iron 1 inch by 7/8ths by 1/8th inch thick, suspended in 15.1 per cent acid solution, 50 c.c.'s of said solution in the same type of container previously used, at

the temperature previously referred to, 85 degrees Fahrenheit, the same length of time, 16 hours. We have tested the effect of adding to originally pure acid different amounts of copper, increasing amounts, different amounts of lead, different amounts of iron, and then various combinations of two of each of these different materials in solution, and we have such data available.

Q. Also, as I understand, various combinations of all three of them, did you not? A. Yes, we did that also. We made one fairly extensive series in which we used combinations of all three of the metals: copper, lead and iron in combination.

The Court: Let me ask you as to your final conclusion on all this; do you find more copper and more lead and more loose iron floating around in this acid in the transportation tanks which you can reasonably account for than if they buy commercial acid, pump it in the ordinary way through the brass fixtures that are likely to be around, and into a tank with the lead in it, lead got it in,—do you find any more than you think would be accounted for in that way? A penny's worth in the water, perhaps. Take it together. Do you think you have found more of the free iron and lead and copper than could be accounted for in that way, if handled in the ordinary way? A. Well, it would seem that the acid must have been handled a number of times in one way or another between the point of manufacture and the point of storage in the storage tank, handled by various devices, and that would seem to represent about the normal amount of elements that one might expect the acid to take up in transportation or in handling and there is, of course, much more of these elements in the truck samples than we have found in such storage samples. That is about the best argument, it seems to me.

The Court: To put it in a rough sort of a way, in a wicked sort of way, do you think that they stuck some of this particular stuff in there? Is that your conclusion? Or, is it your conclusion that this can be accounted for by

the handling? A. Personally, naturally, I prefer to think that in their handling in some way that got in.

The Court: You think in the normal way of handling—in the normal ordinary handling of this, assuming now that they have the lead in, that is something they have added, but that the amount of lead they have got in, and the way they have got that arranged in their transportation tank, you think this quantity can be accounted for by that lead in the acid, and the iron that is there, added to what little will come in through commercial acid, or with a commercial acid, and the ordinary uses of it with ordinary pumps and tools? A. It just happens that I have not analyzed any commercial acid with copper content as high as we find in the truck acids, and I would hesitate to answer that question without having some basis for it.

The Court: Well, you see, I am interested right now, I am wondering whether I have got enough to make me suspicious that they—that is, whether you intend by this proof to create a suspicion—it is all right to do it, but there is something—put them on their proof—that they have added something, or whether the result of all of it, as a result of this you think I should draw the conclusion that it is all explained by the natural, ordinary use of this, coupled up with the plates of lead.

Mr. Owen: I think that that is all we contend, Your Honor. We do not contend that they have placed a chunk of copper, or any copper oxide or chloride in these tanks.

The Court: The rest of it then, all except that plate of lead, is just the ordinary way of handling this material.

Mr. Owen: No, it is not an ordinary way.

The Court: Well, that is what I want to know. Just what is it?

Mr. Owen: It is perfectly possible to handle this material in such a way that there will be no more copper and lead in the acid when it is put into the well than there is when it is in the storage tank.

The Court: You are talking now about not using the lead?

Mr. Owen: Not using the lead, and not using the steel tanks to transport it.

The Court: Well, all right. We will couple that up then. You claim that they should not use steel tanks with the lead. Is there anything else now that they have done?

Mr. Owen: If they use copper or bronze fittings, and the copper comes from those, they should not use those.

The Court: I am asking whether or not there is any claim that it is more than the ordinary use of copper—

Mr. Owen: With the equipment they use, no, it is no more than what you might naturally expect—

The Court: You claim that in order to avoid the infringement of this they have got to be careful to see to it that there is not any copper around in any of their pumps, or in any of their tools?

Mr. Owen: Yes, they have got to see to it that they do not add any of those inhibiting materials to their acids.

The Court: Well, I was getting at your contention about this.

Mr. Owen: If they use conventional methods of transporting their acid they won't have these impurities.

The Court: Well, now, I understood the witness, and he explained to me in the ordinary use of it you might get some of these things added, and there might be some copper quite naturally, and ordinarily, as I understand it, in some of the tools, and that there might be a little bit in the water. Not enough to account for anything much.

Mr. Lyon: Certainly they wouldn't allow us to use the Gravell patent, which is earlier than theirs.

The Court: Have you got anything, Doctor, here from which you can get any idea of how much of this is from the iron tank and the lead plate in the iron tank, and how much from all these other sources outside that have been referred to in the testimony? Is there any way at all? A. I haven't enough information to make any exact quantitative calculations, Your Honor. I regret that I haven't.

The Court: I see the difficulty of it. And these questions aren't in criticism of anybody at all. I understand

this, that you don't complain at all about the amount to be found in any of these storage tanks?

Mr. Wiles: No.

The Court: Then we won't worry about whether they got it in there through some pipes with brass on or not.

Mr. Wiles: No. It is in there.

The Court: Then, what you are talking about is entirely the increase that comes from the lead plates with the iron tank?

Mr. Wiles: Of course, we don't know exactly where it all comes from. It comes somewhere in their method of handling. There is no doubt about that. My own personal guess—we haven't samples of these tanks, but we do know there was a copper bearing steel which is rather extensively used for tankages, because it doesn't corrode as easily as straight steel, and I would make a guess that they probably have copper bearing steel tanks.

The Court: Do you complain about that?

Mr. Wiles: Yes, I don't complain about anything they do excepting putting inhibited acid down a well, and I don't care how they get it inhibited.

The Court: Some of this inhibition you are proving evidently it came in there perfectly naturally, and wouldn't be hardly possible to avoid. That is what we find in this storage tank, I take it.

Mr. Wiles: There is practically nothing there. The copper is way down.

The Court: There is some there?

Mr. Wiles: Traces, certainly.

The Court: And, as I understand it now, maybe I am wrong, it is because they increase that as a result of using those lead plates and an iron tank?

Mr. Wiles: Yes. Probably a copper bearing iron tank.

Q. (By Mr. Owen): You stated that you had made tests with different additions of copper to 15 per cent C. P. hydrochloric acid, and with different additions of lead and of iron. Will you state in a general way, before going into the details of your experiment, what those tests showed?

A. Those tests show that a very small amount of copper tended to inhibit the corrosive action of the acid against iron; and that as the amount of copper was increased, the corrosive action was decreased, of the acid.

Q. Within any limits? A. Yes. The greatest reduction in activity came with very small amounts of copper, one part to three or four parts per million is the greatest rate of decrease. Reaching three and a half parts of copper per million with copper alone with the C. P. acid, the per cent reduction of corrosiveness was 33 per cent, meaning that the acid was about 67 per cent as active as it would have been had the copper not been present.

Q. Now, let me understand you, doctor, was anything else added to that C. P. acid besides the 3.5 parts per million of copper, in this test that you have just referred to? A. No, nothing but the 3.5 parts per million of copper, and the corrosiveness of the acid was reduced 33 per cent.

Q. Now, can you give similar information regarding the addition of lead? A. 320 parts per million of lead gave a reduction of corrosiveness of 12 per cent without adding anything but the lead. It happens that the 320 parts per million of lead isn't far different from some of the lead we found in the acid samples. The extent of reduction in corrosiveness was 12%.

Q. How about the 3.5 parts per million of copper being about what you found in the defendant's treating acids? A. That was close to what we found in the defendant's treating acid.

Q. And have you carried the addition of copper beyond 3.5 parts per million? Did the inhibitive effect increase with the increase in proportion of copper? A. Not nearly at such a rate. For example, 5 parts per million of copper gave a reduction in corrosiveness of 37. 3.5 parts gave a reduction of 33; 10 parts per million, 38; 40 parts per million, 39.

Q. So that the 3.5 parts per million appears to be about the critical point of the increase in the reduction in corrosiveness due to the addition of copper, is that true?

A. It was a critical concentration. It gave nearly as high a reduction in corrosiveness as much greater concentrations.

Mr. Lyon: Did you say how much 1 part per million will do? Have you given that figure? A. I haven't given that figure. 1 part per million, 20% reduction in corrosiveness. I have no figure lower than one part per million of copper. I have figures higher than 40. I have figures up to 100 parts per million, which gave 40% reduction in corrosiveness. That was essentially the same as 40 parts per million.

Q. What were the results of your tests adding iron to the C. P. hydrochloric acid? A. We added both ferric iron and ferrous iron; adding ferric iron gave relatively little effect—as much as one-thousand parts per million gave an effect represented by per cent reduction in corrosiveness of 4%.

The Court: How can you say that iron is an inhibitor? If it was you couldn't use any hydrochloric acid down there at all. You will have iron down there and it will eat the iron. A. Your Honor, there is the possibility of iron existing in two forms—ferric and ferrous, setting up some type of reaction of the metals which might bring about some type of inhibition, but, as a matter of fact, we found there was exceedingly little inhibiting reaction of iron and the ferrous iron gave us no inhibition. As we have shown, the ferrous iron has apparently no inhibiting action; if it happens to be in the ferric form it might have a slight inhibiting action.

Q. (By Mr. Owen): In what form did you add the copper and the lead? A. We added these metals as chlorides. We added copper chloride and lead chloride to the C. P. acid.

The Court: This iron you found was not the free iron? A. No, in the form of a salt. In the form of iron chloride. Probably very nearly all of the iron that had been eaten off the tank was in the form of salt in the solution.

The Court: You see, I didn't have that idea about it. Now, the lead that you find, as I understand it, is because

of some sort of electrical plating action that started to go across to the iron walls somewhere and it got lost in the woods on the way over, and you found it floating around in there? A. Yes.

The Court: Has that got into lead oxide or lead something? A. Yes, lead chloride.

Mr. Owen: Just the same reaction that forms the iron, of course, that forms iron chloride. A. One forms iron chloride and the other lead chloride.

Mr. Wiles: The copper also is in the form of a salt in solution. A. Yes. Any copper present likewise would react with the hydrochloric acid and form a copper chloride, and that would be as a salt in solution.

Q. (By Mr. Owen): And I believe you testified that the copper and the lead and the iron which you added to the C. P. hydrochloric acid in making your tests was in the form of chlorides, copper chloride, lead chloride and iron chloride? A. They were in the form of chlorides before we added them to the pure acid, yes.

Mr. Lyon: Would the copper chloride tend to plate out on the wall of the tank under the battery action the same as the lead chloride? A. Essentially the same.

Mr. Lyon: Excuse me, Mr. Owen, but the witness started to tell us the effect of the addition of different amounts of lead. He gave the answer on copper, and started with lead, but he did not finish that. I should think that you would want him to finish that before he goes into the combinations.

The Witness: I referred to the concentration of 320 parts per million of lead, and stated that that much lead in the acid caused a reduction in corrosiveness of 12 per cent. Increasing amounts of lead produced relatively smaller effects. 620 parts of lead per million gave a per cent reduction in corrosiveness of 14 per cent, and 1000 parts per million gave a reduction in corrosiveness of 15 per cent.

Mr. Owen: Doctor, how did the most effective proportions of lead and copper in your tests, where you added those metals to the C. P. acid, compare with the amounts

of lead and copper chlorides which you found in the defendant's treating acids? A. Maximum,—close to maximum effects were reached when three and a half parts per million of copper to 320 parts per million of lead were taken together. Taken together in those proportions, they gave a reduction in corrosiveness of 38 per cent.

Q. Have you a table, Doctor, which shows the results of your tests, in which you added copper, lead and iron to C. P. hydrochloric acid? A. Yes, I have such data in my table XVIII.

(Table XVIII was offered and received as PX-166.)

The Court: When you take that combination of iron and copper, which you mentioned, in which you get your maximum of inhibition, as I understand it, do you explain that particular portion—does that advantage result from the fact that there is a coating on the thing that you want to inhibit the action on? Or does that all result from the salts that are in solution? It seems to me that there are two kinds of inhibition that bother me in a way. Is there any way that you can give me any idea as to their comparative force in producing this inhibited result? A. In a general way without going into detail of the mechanism I think it would be quite safe to state that the coating effect of copper in an amount represented by as little as 3½ parts per million would be sufficient to so coat the iron that the action of acid would be very greatly inhibited as we do find it; that there is sufficient copper there to form probably a complete molecular layer over the entire iron surface.

The Court: Do they call something that does that an inhibitor? A. They might, yes, because inhibition really refers to a cutting down of a process, and that would certainly tend to cut down the process considered as the whole.

The Court: There are,—or, aren't they recognized as two decidedly different things, one that would put a coating on something and fix it so it can't be equal to the acid like my Parker rustproof case, and another thing that you put something into it so that they will associate together side by side, and one won't eat up the other? It seems as though one is almost—A. (Interrupting): It is to a degree.

The Court: And this very thing I am talking about enters quite a little bit into the theory that later the plaintiff wants to talk to me about, about the using up of this acid and making it so it isn't desirable for its use in the rock. This very thing you and I are visiting about now gets right over into that problem, in my judgment. A. Of course, if the acid is inhibited and the inhibition consists in the deposition of metal, say copper on the iron, in such a way that the action ceases, why then there is no further need to worry about the action of the acid on the iron. We can say that the system is inhibited. But if the acid had contained none of this inhibitor, copper, to set up this action on the surface, why then the reaction could have gone on unhindered quite indefinitely.

Q. (Mr. Owen): What effect would that have upon the strength of the acid? A. The strength of the acid would decrease in that case.

Q. (Mr. Wiles): I want, if I may, to bring out the difference in the two theories you have spoken about. As I take it, one of the explanations is an unbroken uniform or continuous coating of copper, which keeps the acid off the steel. A. Right.

Q. And now, the other one is exemplified, as I understand it, if the coating is spotted, copper, just spots here and there on steel. Now, will you try to make clear the mechanism of how those spots of copper would prevent the acid from attacking the steel in the uncoated parts? A. Probably the most substantial explanation would be that one of the constituents might be absorbed on iron, and in that way tend to change the polarization of the system. For example, in some of the old style dry batteries that I think of, the old carbon cells in which the two electrodes were placed down in the electrolyte, current would flow for a short time and the current would stop, stop because the system had become polarized we say. The hydrogen could not escape. By adding some oxidizing agent to the system which would make possible the liberation of hydrogen, hydrogen would be liberated and the current would flow and continue. And

it is just about the same type of picture which is offered to account for the inhibiting action of metals such as iron—

Q. (Mr. Wiles interposing): Can't you put them on the blackboard so we can all see it? A. Well, suppose one has two electrodes, iron and lead, the electrolyte being hydrochloric acid, and we will assume fifteen per cent hydrochloric acid. Now, it is a little dangerous to speculate offhand which way the current is going to flow in that system. One might predict that the iron would go into solution and the current would flow that way, toward the lead electrode, and the iron would be deposited. That wouldn't be a bad speculation because from the table of the electromotive series one might expect that.

But when one actually carries the experiment out, he finds that it goes the other way, that the lead goes into solution and deposits on the iron. And so, if one has a coupling of that sort, it is true that a certain amount of the lead, as the lead from the plates in these tanks, will go into solution, pass through the acid, and the lead will be deposited on the surface of the iron.

Mr. Owen: Well, now, Doctor, when the lead goes into solution, what is it in the electrolyte? A. When the lead goes into solution, when it leaves the electrode in the electrolyte, it is lead chloride.

The Court: And if you were to stop that at any instant and analyze your solution you would find some of those that, as I have said before, got lost, whatever you want to say, they haven't yet become deposited and they have left the lead, isn't that right? A. That is right.

The Court: You would find some. A. In solution.

The Court: But the probability is you will find some iron in solution. A. And in the beginning there will be a certain amount of iron going into solution as well as lead, so both lead and iron would be found in the solution.

The Court: But that, for some reason, doesn't seem to be strong enough to swim clear across, and you don't find that coating on the lead, as I understand. A. That is right, Your Honor. It doesn't tend to come out forming a coating on the lead.

Mr. Owen: Now, Doctor, will you explain what the reaction is when the lead goes over and coats on the iron? A. If the lead goes over as lead chloride, when it comes in contact with the iron it deposits and forms metallic lead. It goes from the lead in solution to metallic lead.

Q. If the lead was coated on this iron electrode in the presence of hydrochloric acid what would occur? A. Of course, the current, flow of current would stop then, because, in effect, one would have two lead electrodes.

Q. Then, what would take place if both electrodes were either lead or covered with lead? What would take place? A. Well, the acid would tend to eat them off there.

Q. Before we leave this question, I just want to ask the Doctor if this field of electro-chemistry is not a different field from that in which you are devoting your time at the present time? A. At the present time, yes, that is correct.

Q. And you do not pose as an electrochemist of the last word, do you? A. At the present time, you mean? No.

The Court: I just want to thank you for having answered my questions.

Q. What you have done is to just answer the judge's questions to the best of your ability? A. I have, without attempting to refresh my mind on the points.

Mr. Wiles: I think there is one question that might be asked, which might help to clear this up, and that is, the Grebe and Sanford patent, Doctor, gives a specific illustration of arsenic as an inhibitor. Would you differentiate the mechanism of inhibition by arsenic from the mechanism of inhibition by copper, except as there is a difference in the degree of effectiveness?

Mr. Lyon: Is he speaking now of what distinction the patent makes, or outside of the patent?

Mr. Wiles: The patent does not mention copper.

Mr. Lyon: Oh, yes, it does. It defines an inhibitor in line 75, page 1, as a substance capable of inhibiting the attack of the acid upon metal surfaces, *e.g.* of iron or steel, copper, etc., with which it comes in contact.

Mr. Wiles: I am speaking of the inhibition of the acid against steel and copper on the one hand, and by arsenic on the other. Would you differentiate between the mechanisms, or are they the same, approximately the same, in your judgment? A. Well, broadly speaking, I should say that they are the same, broadly the same.

Q. (Mr. Owen): Will you refer to your Table XVIII, PX-166, and explain what it shows? A. In the table I have brought together the data obtained when small amounts of copper or of lead or of iron or of combinations of these metals were used, in studying the per cent reduction in corrosiveness. At the beginning of that table, the solutions are numbered, 1 to 7, consecutively, and there are indicated the results obtained when copper in amounts ranging from 1 part per million to 100 parts per million are used.

The Court: That is just your own arbitrary selection of these amounts? A. It is.

The Court: They are not samples or examples taken from any place, but you just fixed those up? A. I selected them to cover a sizeable range.

The Court: That is the way I understand it? A. And the percentage of reduction in corrosiveness runs from 20 to 40. The greatest effect comes with the increase in the small amounts of copper from 1 to 3½ p.p.m., the reduction stepping up from a 20 per cent reduction at 1 p.p.m. to a 33 per cent reduction at 3½ p.p.m. From 15 p.p.m. to 100 p.p.m. of copper the increase in corrosiveness is only 3 per cent.

Mr. Lyon: Didn't you find copper in the commercial acids that you analyzed? A. Yes, we did. From 24 hundredths parts per million to 37 hundredths parts per million, I believe.

The Court: You think I would be justified in reaching the conclusion that if you increased this beyond 100 parts per million of copper you would never get very much above 40? A. I wouldn't expect to, very much.

Q. (Mr. Owen): Well, now, Doctor, refer to the additions of lead and state what your tests show in that respect. A. Ten parts per million of lead added to the chemically

pure acid gave a per cent reduction in corrosiveness of 4. 40 parts gave a reduction of only 3%. I cannot account for that. It just happened that way. When you get up to 160 parts, you have a reduction of 6%. 320 p.p.m. gave 12 per cent reduction; 420 parts, 13 per cent reduction; 620 parts, 14 per cent reduction, and 1,000 parts, 15 per cent reduction. This was lead alone. No, copper.

Q. (Mr. Owen): So that the greatest percentage of increase there appears to have been from 160 to 320 parts per million; is that right? A. Yes; that is right.

The Court: And there isn't any theory that you know of to explain that? A. No.

The Court: It just does it? A. That is right.

Q. (Mr. Owen): How does 320 parts per million of lead compare with that found in the defendant's truck samples? A. Of the same order or magnitude.

Q. Well, now, go on to the next section of PX-166, referring to ferric iron and ferrous iron. A. Using different amounts of ferric iron varying from 300 parts per million to 1,000 parts per million, we found that the 300 parts per million gave a per cent reduction in corrosiveness of about one per cent; 440 parts, 3; 700 parts, 4; and 1,000 parts per million, approximately 4. In other words, the ferric iron had but very little effect in reducing the corrosive action. The ferrous iron in amounts from 300 parts per million to 1,000 parts per million had practically no effect in reducing the corrosiveness.

Q. And what is the difference between ferric iron and ferrous iron? A. Well, the ferric iron is one form of iron, a form of iron which, in solution, gives ions of a certain charge, and has a valence of 3, and the ferrous iron, in solution, has a somewhat different property. It is said to be di-valent, and has an electrical charge such that its valence is 2. The formula for ferric iron is $FeCl_3$, and for ferrous iron is $FeCl_2$.

The Court: I take it that there is no theory at all as to why 700 parts of the ferrous iron did give one per cent and the other didn't give anything even when you went up to 1,000? A. No, I have no explanation to offer of that.

The next section of the Table we used copper and lead. In the next section, the amount of copper was kept constant at 3½ parts per million, and the lead was varied from 10 to 1,000 parts per million. 3½ parts per million of copper plus 10 parts per million of lead gave a reduction in corrosiveness of 36 per cent. 3½ parts per million of copper and 40 parts per million of lead gave a reduction in corrosiveness of 38 per cent. 3½ parts per million of copper and 160 of lead, 38 per cent; 3½ of copper and 320 of lead, 38 per cent; 3½ of copper and 420 of lead, 38 per cent; 3½ of copper and 620 of lead, 40 per cent, and 3½ of copper and 1,000 of lead, 41 per cent.

Mr. Owen: Now, it appears, then, that with the amount of copper constant at 3.5 parts per million the inhibitive effect of the addition of lead was the same whether you added 40 parts per million of lead or up to 420 parts per million of lead. A. That is right.

Q. Is there any explanation for that? A. Well, no simple explanation other than the 40 parts per million of lead seems to be a sufficient amount of lead to give practically a maximum effect with the 3½ parts of copper.

Q. Then your table also shows the effect of small additions of ferric and ferrous iron to solutions containing 3.5 parts per million of copper. A. Yes, the addition of ferric iron gave but little effect. Adding 300 parts per million to the 3½ parts of copper gave a per cent reduction in corrosiveness of 33%, which was the same as the 3.5 parts per million of copper alone. 440 parts gave but 34%, 700 parts 33% and 1,000 parts 34%, which means that the ferric iron had practically no effect on increasing the reduction in corrosiveness of the copper.

Q. And what was the effect of adding small portions of ferrous iron with the same amount of copper? A. They showed essentially the same type of result as the ferric iron; adding from 300 parts per million up to 1,000 parts per million of copper in the acid gave values of 34, 34, 33 and 34 per cent, which mean that the ferric iron was practically without effect.

Q. In the next section of your table you have shown the effect of different combinations of copper and lead and of lead and iron with the lead kept constant at 420 parts per million. Please refer first to the portion showing combinations of copper and lead and give the results. A. When 1 part per million of copper was taken with these 420 parts per million of lead, about 30% reduction in corrosiveness was obtained. 3½ p.p.m. gave 38%, 5 parts 40%, 10 parts 41%, 40 parts 42%, 80 parts 42%, 100 parts 43%. So that by adding increasing amounts of copper to the solution containing also lead of a constant amount very nearly maximum effects were obtained with the 3½ parts per million of copper. From that point on increasing the amount of copper did not materially increase the per cent reduction in corrosiveness.

Q. Right in that connection, and in order to refresh the mind of the court, will you state approximately the average amount of copper and the average amount of lead found in the defendant's truck samples?

Mr. Lyon: Your Honor, it doesn't seem to me that these averages are anything but misleading. There is no such thing as an average infringement. We ought to have actual, if we are going to make determinations within two or three parts of a million, it seems to me we ought to have exact quantities compared. Averages just mix everything up in a scramble.

Mr. Owen: I will ask the witness to state the average amount of copper found in the Stella Wilcox samples, and the average amount found in the Zahn samples, and the average amount found in the Crawford samples, each separately? A. The average amount of copper found in the Stella Wilcox samples was 3.6 parts per million. The average amount found in the Zahn samples was 3.1 parts per million, and the average amount found in the Crawford samples was 4.8 parts per million. Now, taking an average of those three values: 3.6, 3.1, 4.8, would give 3.8.

Q. And, now, will you state the average amount of lead you found in the Stella Wilcox samples, and in the

Zahn samples, and in the Crawford samples, stating each separately? A. The average amount of lead in the Stella Wilcox samples was 417 parts per million, in Zahn 437 parts per million and in Crawford 53 parts per million.

Q. So that in Crawford the copper was higher and the lead was lower than in the other samples? A. It was.

Q. Now, take each of the truck samples separately, that is, the average of the Stella Wilcox, the average of the Crawford, and the average of the Zahn, for copper and lead content, and point out which of the samples in PX-166 comes the closest to each one of those? A. Well, for the copper and lead in the Stella Wilcox the values are 3.6 and 417; turning now to my table, 3.5 is the closest value as to that 3.6, and 420 is the closest value I have to the 417, which means the solution numbered 27.

Q. And, what is the reduction in corrosiveness shown on your test of that combination? A. The reduction in corrosiveness is 38 per cent.

Q. Now, do the same with reference to the Zahn. A. For the Zahn, the parts per million of copper 3.1; parts per million of lead 435; and the closest I would have to that, apparently, is my No. 27 solution, showing 38 per cent reduction in corrosiveness?

Q. And now as to the Crawford? A. The Crawford, 4.8 and 53. That will be hard to get, that combination. The nearest for the copper alone would be 5, which is solution 37. The nearest to the lead alone would be 40, which is my No. 9 and would give a reduction in corrosiveness of 3 per cent, and 5 parts per million for copper, which is my solution No. 3, gave a reduction in corrosiveness of 37.

Mr. Owen: Doctor, I believe that you had gotten down to solution No. 45 on your table No. 18 (PX-166). Will you take it up from that point? A. Solution No. 45 is one containing lead and ferric iron in this proportion: 420 parts per million of lead, 300 parts per million of ferric iron, which is not far from the ratio found in some of the samples, and gave a per cent reduction in corrosiveness of 12. It was noted that keeping the amount of lead constant

at 420 parts per million, and increasing the amount of ferric iron from 300 parts per million to 1000 parts per million, in steps of 300, 440, 700, and 1000, the per cent reduction in corrosiveness remained practically constant; in other words, increasing the amount of iron from 300 to 1000 parts per million had practically no effect on the reduction in corrosiveness. Referring to my solution No. 12 I find that 420 parts per million of lead alone gave a reduction in corrosiveness of 13 per cent. From that I should think it may be concluded that the addition of the iron had no effect on the solution.

Q. Now, taking up the next section, Solutions 49 to 52, where ferrous iron was added, what effect did that have? A. Well, the data show that when the lead remained constant at 420 parts per million, and the ferrous salt was increased from 300 to 1000 parts per million, the reduction in corrosiveness did not increase. As a matter of fact, the figures show a very slight decrease in reduction in corrosiveness.

The Court: Let me see if I have the right idea out of that, doctor; that there is probably so much of that ferrous iron in the acid—my reasoning would be different all the way—it finally got so much it has kept the acid busy with that added ferrous iron— A. (interposing) It might be speculative that the solution already contains so much iron when 1000 parts per million were present that it tended to retard a bit the normal action of more iron to go into solution.

The Court: Tell me what it was corroding, again? What did you have for it to corrode on? A. The iron test pieces, one inch, by 7/8 by 1/8, for sixteen hours.

The Court: Well, it didn't corrode so much when you put in more of your ferrous iron, when you put in 1000 as it did when you had 700 in? A. It happened it did not get so much.

Mr. Owen: Now, Doctor, take up the next section, beginning with solution 53 and explain what it shows, from 53 to 59 solutions. A. In that section the experiments were conducted by adding to the pure acid a given amount

of ferric iron—440 parts per million in each case, and the amount of copper was varied. The iron was kept constant in the different experiments and the copper was varied from one part per million up to 14 parts per million. In solution 53, containing 1 part per million of copper, 440 parts per million ferric iron the per cent in reduction of corrosiveness was 20. Solution 54 containing 3½ parts per million of copper, 440 of iron, 34.

Q. And how do those compare with the results obtained from those two amounts of copper without any iron? A. Very nearly the same. With the same amount of copper in the acid, 3½ parts per million, the per cent reduction in corrosiveness was 33%, and in this case with the added 440 parts of iron it was but 34%, showing the iron had very little effect.

Q. Am I justified in stating from these tests that the presence of either ferric chloride or ferrous chloride in 15% hydrochloric acid solution has no effect on the rate of corrosion when there is also present small amounts of copper? A. Well, apparently it has but very little if any effect.

Q. Now going to the last section of your table, you show combinations of copper, lead and ferric iron. Will you explain what those show? A. Well, in the first group of solutions from numbers 67 to 70 the copper and lead content is kept constant and the ferric iron content increased from 300 to 1000 parts per million, the copper and lead contents being 3.5 and 420 respectively. The effect of the increase in amount of ferric iron is at most but very slight for the results obtained are, for example, as follows: With 300 parts of ferric iron, the per cent reduction in corrosiveness, 39; with 440 parts, 40, with the 700 parts, 38; 1000 parts, 38; indicating that an increase in the amount of ferric iron when copper and lead are constant has but little effect and, if anything, gives a slightly lowered reduction in corrosiveness for the higher amounts of the iron.

The Court: Well, the adding of any of it doesn't seem to affect it, does it? I don't find much difference whether it is present or isn't present. A. The iron doesn't seem to make much difference.

Mr. Owen: Well, you refer to solution No. 27 in which the same amount of copper and lead were present as in solutions 67 and 70, and the reduction in corrosiveness is 38 per cent, which is substantially that of the same solutions with ferric iron added.

The Court: The adding of the iron to the copper and lead doesn't seem to do much of anything.

Mr. Owen: Apparently not. Apparently doesn't have much effect.

The Court: You have a little difference, but you can hardly run through experiments and not have, I suppose, a trifle difference.

Mr. Owen: Now, the next group from 71 to 77, does that show anything different, Doctor, that you wish to mention? A. In that case the copper was kept constant at 3½ parts per million and the ferric iron at 440 parts per million, while the lead was varied from 10 parts per million to 1,000 parts per million. I will refer to the results obtained in terms of the increasing amounts of lead. With 10 parts per million of lead present the reduction in corrosiveness was 34 per cent; with 40 parts, 37; 160 parts, 36; 320 parts, 37; 420 parts, 40; 620, 40; 1,000, 40. In other words, the maximum effects were obtained with about the 320 parts per million of lead, although as a matter of fact at 40 parts of lead it gave fully as high values. The maximum reduction in corrosiveness was obtained with 420 parts of lead, and increasing it from 420 to 1,000 didn't change the corrosive effect?

Q. What does the last section of these tests show? A. Why, in the last section are tests with ferric iron kept constant at 440 parts per million, the lead at 420 parts per million, and the copper varied from 1 part per million to 100 parts per million. The results show that with the 1 part per million of copper the reduction in corrosiveness was 30 per cent, with 3½ parts per million, 40 per cent; 5 parts per million, 39 per cent; 10 parts per million, 41 per cent; 40 parts per million, 40 per cent; 80 parts per million, 42 per cent; 100 parts per million, 42 per cent.

The Court: What does that show, the whole thing added together, more than that the copper from 1 part to a million up to copper at 5 parts to a million does the main trick, and the others don't do very much? A. I believe it does show that the greatest effect is obtained with the copper from 1 part to 5 parts per million, and that lead does contribute to the effect given by the copper somewhat.

The Court: Well, you haven't shown that the lead has done very much. 1 to 5 and I get clear up to 37. With 5 parts of copper alone I get 37. Now, where do you show anything—

Mr. Owen: (Interposing): I call your attention to solutions 23 to 29. That is the series which shows the effect of adding different amounts of lead to 3.5 copper.

The Court: But you don't get it higher than that, very much.

Mr. Owen: It shows at 10 parts of lead and 3.5 of copper, 36 per cent reduction in corrosiveness, and it goes up to 41 if you increase the lead up to 1,000.

The Court: Yes, but I know 3, 3½ parts of copper to 100 parts, you see, takes it up to 38. Well, 5 parts of copper all alone takes it up to 37. And three and a half parts take you to 33.

Mr. Owen: Yes, the copper is the effective agent, there is no question about that.

Q. (Mr. Owen): Doctor, you have at the bottom of this table one test numbered 85. What is the purpose of that? A. Well, that test shows the effect of the presence of ferrous iron. The copper is present in the amount of 3.5; the lead, 420, and the ferrous iron, 440. The results could be compared with those obtained in solution 75, using ferric iron. With ferric iron, the per cent reduction of corrosiveness was 40; using ferrous iron, 39. It indicates that it makes but little difference whether the iron present is ferrous iron or ferric iron. Neither of them have much effect in reducing corrosiveness.

In all of these tests on my Table 18 (PX-166) I used 50 c.c. of the hydrochloric acid solution, at 85 degrees Fahrenheit with no agitation of the solution.

I made other tests to show what effect agitation and increasing the percentage of the solution to the amount of exposed metal surface would have on the rate of corrosion. I made tests to cover both of these points, first, to determine the effect upon corrosion of agitating the solution during the test. In all of the results that I have reported so far, the solutions were not agitated; the metal strips were suspended in the solution, and the solution remained quiescent. I have prepared a table showing the results of those tests.

(The table was offered and received as PX-167.)

This table shows the results obtained when small pieces of strap iron of the size that we have just been discussing, the 1 inch by 7/8ths by 1/8th of strap iron, were tested for a period of 16 hours, at 85 degrees Fahrenheit, using as solutions the solutions given in the preceding table, my Table No. 18, Solution No. 2, for example in that table contained 15.1 per cent C. P. hydrochloric acid, 3½ p.p.m. of copper and no lead or iron and gave with no agitation, as reported in the other table, 33 per cent. With agitation the value appears in the column following as 44 per cent. So, agitating that particular solution stepped up the reduction in corrosiveness from 33 per cent to 44 per cent. And, then, similar tests were made with some of the other solutions. Solution No. 26 containing, in addition to the acid, 3.5 parts per million of copper and 320 parts per million—

Mr. Lyon: What kind of agitation did you employ? A. The agitation was brought about by placing my vessel containing a metal strip on the platform in a thermostat, and causing the platform to move back and forth, and the metal strip was supported by the small hole through the upper end which I referred to this morning with a glass hook. It was supported in such a way that the movement of the platform caused a swinging of the metal strip in the solution.

Mr. Lyon: Was the solution open to the atmosphere during the test? A. With a very small hole through the stopper which was placed over the vessel.

The Court: Was the liquid moved? A. The liquid

moved somewhat, but the pieces of metal swinging in the liquid would cause, anyhow—it moved by being on a moving shelf which was kept at a constant temperature.

The Court: And, it would all move at that rate except that the suspended iron was free to swing as a result of this motion? A. Was free to swing; that is right, Your Honor.

The Court: There was nothing to move the iron except that its momentum as compared with the momentum of the thing that you moved? A. The platform, that is right, Your Honor. And, a number of tests were made simultaneously on this same platform, the different vessels were set up with these strips of iron and as the platform moved they all were agitated to the same extent, so that all of the results that I report in this table would be obtained with practically the same effect.

The Court: The container was agitated enough to stir or move the liquid within it as to itself and in addition there was movement of the iron through this agitated liquid. A. Well, the 50 cubic centimeters which was the amount of liquid we had in the container, would fill the container perhaps to the extent of a couple of inches, or so the metal strip was suspended down in that liquid. Now, the movement of the strip certainly would stir the liquid in the container and agitation would stir it some, but not as much as the movement of the strip would stir it.

The Court: Then in addition to agitating the liquid it caused a movement of the liquid past the surfaces of the iron? A. It did, yes.

The Court: How rapid was that, again? Like a malted milk shaker? A. It didn't go that fast. Perhaps a round trip of the platform per second, something like that.

Mr. Owen: Now, will you go on with your explanation, Doctor, please? A. Using solution No. 26, which contained 3½ parts per million of copper, 320 parts per million of lead, no iron, gave without agitation a reduction in corrosiveness of 38%; with agitation, 48%. With the solution No. 30, the C. P. acid with the 3½ parts per million of copper, no lead, 300 parts per million of ferric iron, with no agitation gave

33% reduction in corrosiveness, and with agitation, 43%. The solution No. 34, with the C. P. acid 3.5 parts per million of copper, no lead, 300 parts per million of ferrous iron, with no agitation, 34% reduction in corrosiveness, and with agitation, 43%. Solution No. 68, in the C. P. acid, 3.5 parts per million copper, 420 of lead, 440 of ferric iron, it gave without agitation 40% reduction in corrosiveness, and with agitation 52%. Solution No. 85 contained besides the acid 3.5% parts per million of copper, 420 parts per million of lead, 440 parts per million ferrous iron, gave, without agitation, 39% and with agitation 50% reduction in corrosiveness.

Mr. Lyon: Doctor, these were percents of what? The same chemically pure? A. As I previously calculated. The percentages against blank acids.

Mr. Lyon: Were the blank acids agitated? A. Of a similar strength, yes.

Mr. Lyon: The blank chemically pure acids? A. Yes.

Mr. Lyon: You haven't any data here on that? A. I haven't data on that.

Mr. Lyon: Have you got it in your notes? A. I can get it for you. I can't say how soon. It is either here or at Ann Arbor.

Mr. Lyon: I would like to have it because you brought in the comparative data from which you calculated what was 100% in the case of the other tests, and I would like to see it in connection with these. A. I can furnish you with the data. If I don't have it typed, you will have to wait until I get it up here.

Mr. Lyon: Did you repeat any of your other work on agitation tests or just agitated these special samples made of C. P. acid with these particular parts of copper, lead and iron in them? A. As I recall, our tests are limited to these synthesized samples. I would want to leave the loophole to supply the information if by chance we were able to run the others. I don't recall that we did.

The Court: Have you any theory as to why agitation increased the reduction in corrosiveness? A. I think I probably have a theory which might account for it. It may

be that the inhibiting agent can more readily get to the metal if the solution is agitated so as to bring a greater volume of the solution in contact with the work per unit of time. There is but a limited amount of the agent in contact with the surface. The agent must diffuse through the solution to get to the surface. Now, perhaps after the agent is rather depleted near the surface, the motion of the plate out into new liquid would bring it in contact with more of that—

The Court (interposing): Stronger. A. (continuing) —agent, which is present in small amount.

Mr. Lyon: What I don't understand, Doctor, is whether the blanks which represent the one hundred per cent against which you tabulate these percentages here, whether when they were agitated that increased the amount of corrosion or decreased the amount of corrosion in the blanks? A. Well, I will attempt to get you that data.

Mr. Lyon: Doctor, don't you remember whether it did or did not corrode more when you agitate the blanks? You have all the measurements. A. Just for the moment I haven't those figures in mind. I can refer to my data here. (Refers to data.) Your Honor, I think I can answer the question now, and I can furnish the data, if necessary. It just happened that the blank sample showed very little change in the rate of reaction but it was the inhibited sample that was slowed down by the agitation.

Mr. Owen: Will you make your answer a little more complete? You mean that the blank showed little change in the rate of corrosion under agitation from that when it was not agitated? A. When it wasn't agitated.

The Court: What about that blank you are talking about? You are talking about this chemically pure solution. A. Yes. With a chemically pure solution it just happened that the amount of action, corrosiveness, was practically the same whether the solution was agitated, as I have described, or not.

Mr. Owen: Which solution are you speaking of now? A. With the C. P. Acid, and no added metal. We took one

sample and permitted the vessel to remain without agitation for a period of sixteen hours, and measured the loss in weight of that metal. And another sample the same weight, same body of liquid, same temperature, agitated as I have described, for sixteen hours, and it showed a slightly lesser loss of weight than the one which was not agitated: showing that agitation, in that particular case, decreased the corrosiveness.

The Court: That is what I expected, and I still feel this shows it. Maybe not.

Mr. Owen: I think it does.

The Court: That would be just in accordance with this. In other words, when you add it in then you didn't eat quite so much? A. That is right.

The Court: When it was not inhibited? A. When it was not inhibited it reacted at about the same rate whether agitated or not.

The Court: Then the only surprise to me is, when there was not an inhibitor in, it did not have the same effect. That is a surprise to me.

Mr. Owen: I think perhaps the doctor can explain that, at least theoretically.

The Court: All right.

Mr. Owen: What is your theory on that, Doctor? A. Well, the explanation as to why the movement of the liquid, or, why agitation tended to favor inhibition, the explanation I made a few moments ago is that the inhibiting agent in this is present in small amounts, and perhaps the solution immediately adjacent to the metal becomes but slightly depleted; while agitation may bring the plate in contact with fresh solution containing a sufficient amount of the inhibiting agent so the action is more rapid and pronounced, perhaps.

Q. Now, proceed with your explanation of your Table XIX (PX-167). A. We carried out another set of experiments using the same kind of metal, same temperature, length of time, and so forth, and using the same kind of solutions just described in the last set of tests. We used

a solution with a composition of our No. 2, for example, but instead of using 50 c.c. of the solution with agitation, we used 300 c.c. of solution.

The Court: But no more of the copper? A. The same amount of metal but instead of using 50 c.c. of the solution containing the 3½ parts per million of copper, for example in solution No. 2, we used 300 c.c. containing 3½ parts per million of copper.

The Court: You used six times as much solution but the same constituents of every kind? A. That is true, Your Honor.

The Court: And the only thing you didn't increase was the iron suspended. A. That is true.

Mr. Lyon: Your Honor, I would like to know if they figure the percentages against a new experiment with chemically pure acid with 300 c.c. or did they figure the 100% against this old blank they have used in here which only had 50 c.c. A. Naturally it was with the solution with the 300 c.c.

Mr. Lyon: You have no data on that? A. No.

Q. (Mr. Owen): Now, Doctor, continue. A. The results obtained in this case with the solution of C. P. acid containing 3½ parts per million of copper, no lead, no iron, gave a reduction in corrosiveness of 63% when agitated; a corresponding solution of 50 c.c. had given a reduction in corrosiveness of 44%. Passing on to solution No. 26 containing 3½ parts per million of copper, 320 parts per million of lead, it gave a reduction in corrosiveness with 300 c.c. of solution, agitated, of 63%. Solution No. 30 containing in addition to the acid 3½ parts per million of copper, no lead, 300 parts ferric iron, gave with agitation a reduction in corrosiveness of 64%. Solution No. 34 with 3½ parts per million of copper, no lead, 300 parts per million ferrous iron, gave a reduction in corrosiveness of 64%. Solution No. 68 in addition to the acid with 3½ parts per million of copper, 420 of lead, 440 ferric iron, gave 63%. Solution No. 85, in addition to the acid, 3½ parts per million of copper, 420 of lead, 440 ferrous iron, gave a reduction in corrosiveness of 65%.

The Court: What do you suppose the result would have been if you had another column of 300 c.c. solution with no agitation? A. I would expect it to behave somewhat as the 50 c.c. solution with no agitation, giving perhaps a slightly lesser reduction in corrosiveness, but that is only a guess.

The Court: You wouldn't expect to get a reduction in corrosiveness, would you, if you had taken 300 c.c.? I mean a reduction from the first column. Take that 33, first No. 2 in the first column.

Witness: Of less than that?

The Court: Where we got 33, it would just increase that to? A. I would expect it to be considerably more. It is unfortunate we have not had an opportunity to run such series. I explained at the beginning of my session on the stand that I had to be conservative of the samples I had and I didn't have enough of the samples to enable me to make runs using as much as 300 c.c. solution.

The Court: I would think if it went either way it would reduce that.

Q. (Mr. Owen): I wish, doctor, you would bring with you either tomorrow or next week the data you have showing your tests of the blanks corresponding with the first and third columns of figures in your Table 19. Is that clear to you? A. That would be the first column, the one above the 33 per cent, and the third column, the one above the 63 per cent.

Mr. Lyon: I would like 44, too.

Mr. Owen: All right. If you made blanks for the others beginning at 44 bring those, also.

The Witness: I will be glad to bring such data as we have, and will attempt to get that assembled and in order.

Mr. Owen: Doctor, at the session yesterday you were mildly criticized for having taken averages of averages in connection with your Tables 1, 2, 3 and 4, which are PX-154 to 157, inclusive, and I asked you if you would make up those averages, omitting any reference to averages of minor portions of the tests. Do you understand what I

mean? In other words, I want you to make up averages for those four charts or tables taking only the tests of the different truck acids. For instance, you have three Stella Wilcox No. 8 tests there. I want you to take those three figures under per cent loss in weight, and then I want you to go to the next sample, 12-B, Zahn, and take those three figures under per cent loss in weight, and so on down, and don't take any average of averages of the individual groups, but take one average of all of them. Take Table 1. The average would be of 2.02, 2.02, 1.98. Then you jump down to the third group, sample 12-B, and you take 1.80, 1.81, 1.81, and then you jump to the sample 5 of the Stella Wilcox and take 3.23, 3.30 and 3.22, and so on down, and when you get all those grouped take the average of them. Is that clear? A. I think I see what you mean now.

Mr. Owen: During yesterday's session, reference was made to the dates when the defendant purchased commercial hydrochloric acid, and placed it in its storage tanks, and counsel have agreed to stipulate that if Mr. J. J. Edwards were called to testify as a witness in this case, he would testify that he is manager of the Mt. Pleasant branch of the defendant in this case; and that he would further testify in accordance with the testimony given by him in his deposition taken in Mt. Pleasant on June 28, 1939, and I will read that portion of the deposition into this record. This is part of his direct examination.

(Reading): "Q. I asked you yesterday if you would bring data regarding the receipts of acid. Did you do that? A. Yes, sir. (Handing same to counsel).

"Q. What is it you have produced? A. Halliburton Oil Well Cementing Company monthly acid inventory."

This, of course, means the receipt of acid by the defendant company at its Mt. Pleasant station.

"Q. And what do these data sheets show? A. Show the district, the month ending ..., the year, and show the date raw acid was received, gallons of, Baume, the dates that raw acid was sold, the ticket number, gallons and Baume, the balance on hand, gallons and Baume.

"Q. Does it show the source of the acid? A. It shows from whom the raw acid was received and what was brought forward from the last report.

"Q. Will you please refer to data sheets you have produced and give the date on which each shipment of acid was received, the name and address of the company from whom it was received, the quantity received and the Baume? A. This does not list the address of the company from whom we received that.

"Q. Just give the name then, please? A. 4-23-38 we received from the Pennsylvania Salt Manufacturing Co., 3976 gallons 20 Baume acid (reading from the record).

"Q. Do you know the location of the plant from which that acid was shipped? A. I believe it was shipped from Wyandotte, Michigan. I am not positive of that. (Witness continuing): May 2nd, 1938, from Pennsylvania Salt Manufacturing Company, we received 3,914 gallons 20 Baume acid. May 3rd, 1938, from Pennsylvania Salt Manufacturing Company, we received 3,945 gallons 20 Baume acid. May 21st, 1938, from the General Chemical Company we received 6,075 gallons 20 Baume acid.

"Q. Do you know which General Chemical Company plant that was received from? A. I believe that came from Chicago.

"Q. And does that apply to all the later shipments from the General Chemical Company? A. I believe so. (Witness continuing): May 23rd, 1938, from the General Chemical Company we received 5,982 gallons of 20 Baume acid. June 15th, 1938, from the General Chemical Company we received 5,993 gallons of 20 Baume acid. June 15th, 1938, again we received from the General Chemical Company 7,824 gallons 20 Baume acid. July 24th, 1938, from the General Chemical Company we received 6,013 gallons 20 Baume acid."

And, interrupting his deposition there I will state that that appears to have been the last acid received prior to August 27th, 1938, when they received another carload from the General Chemical Company, and in the meantime the

Stella Wilcox treatments and the Zahn treatments were made. And, continuing the deposition:

"August 27th, 1938, from the General Chemical Company we received 5,938 gallons 20 Baume acid. August 17th, 1938, from the General Chemical Company we received 7,866 gallons 20 Baume acid. And that is the last."

This deposition, Your Honor, was given on June 28th, 1938.

And, continuing:

"Q. Will you state approximately the gallon capacity of your storage tanks? A. Our storage tanks approximately are of 10,000 gallon capacity each.

"Q. Do I understand correctly you have received no hydrochloric acid since October 17, 1938? A. To the best of my knowledge that is right. We don't indicate one here. (Witness looked through tickets). Our inventory doesn't indicate we have received any acid since that time.

"Q. What amount of acid did you have on hand after you received that last shipment? A. After receiving the shipment on October 17th this brought our storage up to 26,695 gallons, 20 Baume acid.

"Q. How is that acid delivered to you? A. By tank car, railroad tank cars.

"Q. And what is your practice regarding the unloading of the acid when the cars are placed on your siding? A. We removed the connections at the top of the dome of the tank car and put, I believe it is an inch and a half rubber discharge hose, from the dome through the opening into our storage tanks. There is another connection on the dome that is hooked up with a small rubber hose running from an air compressor located in our building next to the tanks. The acid is forced from the tank car into our storage tanks by an air compressor.

"Q. Do you customarily remove the acids within a few hours when the tank car is delivered on your siding? A. Customarily."

Now, that ends the portion of the deposition which I wish to read.

And, it is further stipulated that exhibits which were identified as Exhibits 1, 2 and 3 to the Edwards deposition may be received in evidence here as being photographs of the two storage tanks of the defendant company at Mt. Pleasant which have been referred to as the north and south storage tanks. There are two photographs of those tanks, Exhibit 1 shows them standing out very plainly, and Exhibit 2 is taken from a greater distance and a different position, and doesn't show them so clearly. Exhibit 3 to this deposition is a photograph of one of the defendant's truck trailers in which the acid is tranported from the Halliburton storage tanks to the wells where the treatments are given, and in which truck tanks this lead plate arrangement, which has been described, is secured.

The Court: Do you want any exhibit numbers in this case? Now the next exhibit number is PX-168.

(The photographs above referred to were thereupon marked PX-168.)

By Mr. Lyon:

Q. Doctor, you can produce the data showing the tests, the blanks of the chemically pure acid using 50 c.c. and 300 c.c. referred to in connection with your testimony as to Table No. XIX? A. We have that data with us, but it will take some time—a few minutes to find it. I can get it for you today.

Q. Can you compile it and give it to us by Tuesday morning? A. We can give it to you Tuesday morning.

Q. The next item, Doctor, did you not make similar experiments with the plaintiff's commercial inhibited acid? I think the court asked you about that, and I understood you were going to produce that data? A. I don't recall that I have such samples.

Q. Well, do you remember whether or not you had any specimens of acid to which one to five per cent of any of the inhibitors named in the Grebe & Sanford patent in suit had been added, and did you determine the percentage of inhibition by the same method you reported for the defendant's? A. Yes, with the—

Mr. Owen: (Interposing) I will say in that connection,

Your Honor, I have planned to offer proof of that kind this morning. We located it last night and are going to put it in.

Mr. Lyon: I would like to ask this question so we understand what this per cent inhibition means, Your Honor, in our studies of this matter over the week end. If the plaintiff's acid of the patent in suit containing one to five per cent of arsenic oxide shows that it is inhibited 99½ per cent as compared with the percentages that you have reported for the defendant's acid, that means, does it not, that the rate of corrosion of the defendant's acid is at least 100 times that of the plaintiff's own patented acid; is that not correct?

Mr. Owen: He is asking this witness to assume that the plaintiff's treating acid is 99.5 per cent inhibited, and if it is so inhibited, isn't this acid so many times more corrosive than the plaintiff's acid.

Mr. Lyon: I am trying to find out what this percentage means. What I am asking him is if the acid of the patent in suit, employing from 1 to 5 per cent arsenic oxide actually is inhibited 99½ per cent, if that, compared with the figure he has presented here as to the defendant's acid, does not mean that the defendant's acid is 100 times at least as corrosive as the acid of the patent in suit. I want to understand that. That will save us a lot of time.

The Court: I understand, for my purposes at least, that this is purely an arbitrary figure now.

Mr. Lyon: He has not produced a figure as to the plaintiff's acid.

Mr. Owen: The defendant's acid is not uniform. On some groups he gets a higher rate of inhibition than on others. If counsel wants to know the basis on which this computation may be made, I think he should take two arbitrary figures, one for theirs, and one for ours.

Mr. Lyon: I am willing that we should take for the defendant's acid, on the method of calculating that you have used in your tables, that the defendant's acid is inhibited 50 per cent, and that we should assume or take for

the plaintiff's acid, the acid of the patent in suit, that it is inhibited 99½ per cent. That means, does it not, that the defendant's acid is 100 times as corrosive as the plaintiff's? A. The question as asked, which is a hypothetical one, involves this, as I understand it, if the reduction in corrosiveness of one of the acids, referred to as the plaintiff's acid, was reduced to 99.5 per cent and if the corrosiveness of the defendant's acid was reduced in its corrosive action to 50 per cent, then it is quite obvious that the corrosive action of the defendant's acid is 100 times that of the plaintiff. That is correct.

Q. (Mr. Lyon): Now, were you not delivered samples for making corresponding tests from the Stella Wilcox well said to be taken on August 2nd?

Mr. Owen: That has been requested before, and the data is here, and I am going to examine the witness on it this morning.

The Court: Then they are going to answer that?

Mr. Lyon: Fine. Another point I would like to have you examine him on, if you intend to, if not I would like to arrange to get the data; did you examine the commercial acids and the defendant's well acid for the presence of anything except—and the defendant's tank acids, all three or any of them, for the presence of anything except copper, iron and lead? Did you examine them for arsenic or anything else? A. We did not for arsenic.

Q. Well, for anything else besides copper, lead and iron? A. As far as special analysis, no.

Q. Do you know whether commercial acid contains arsenic? If so, in what quantities? A. The ordinary commercial acids may contain traces, but not in any appreciable quantity, not in quantity to bring about inhibition to the extent that we have been discussing.

Q. Does it contain any arsenic ordinarily, commercial hydrochloric? A. We found none in making simple tests.

By Mr. Owen:

Q. Doctor, you were asked this morning whether you had tested the Grebe and Sanford process, using an arsenic

compound as inhibitor. I do not know whether counsel referred to the specific example of the patent or not—did you, Mr. Lyon?

Mr. Lyon: I would like to know what tests he made, using the arsenic chloride of between 1 and 5 per cent by weight in solution—the arsenic oxide.

By Mr. Owen: Did you make any tests using arsenic as the inhibitor in this Grebe and Sanford process? A. Yes, we did.

Q. What tests did you make in that connection? A. We made up a solution in accord with the stipulations of the patent taking the same relative quantities as are suggested in the patent, namely, for each five hundred gallons of 15 per cent acid—

Mr. Owen (Interposing): Let me read the statement from the patent. That is what the doctor is referring to. "For example, to 4500 pounds of a 15 per cent hydrochloric acid solution was added two gallons of arsenic acid solution containing 21 pounds of arsenic calculated at As_2O_5." Did you make up such a solution and test it? A. Yes. We made up a solution conforming exactly to those quantities, and tested it, and obtained a reduction in corrosiveness of 97 per cent.

Q. Now, do you have your notes on that test here? A. I haven't them in an assembled form. I simply have the data in some record I have here. Q. Read into the record what data you have. A. In my records here I have this notation. "Arsenic solution prepared according to the disclosure, Page 2, Line 74 and 78 of the Grebe-Sanford U. S. Patent No. 1877504, reduction in corrosiveness 97 per cent."

Q. Is that all you have here? A. That is all I happen to have here. I have other data available, but it is not with me.

Q. Will you bring it with you for the next session of the court? A. Yes.

Mr. Lyon: I would like to have it before, if we could have it Tuesday morning.

Mr. Owen: You mail a copy of it to defendant's counsel next Monday.

The Court: I am putting this 97 down as a percentage of inhibition. That is right, isn't it?

Mr. Owen: That is right. That is correct.

Mr. Owen: Doctor, how many gallons is 4500 pounds of 15 per cent hydrochloric acid solution? A. Apparently it is about 500 gallons.

Q. And, in your tests of this patent example what proportion, or what amounts of acid and of arsenic did you use, if you have the data here? A. We have the summary, but we can remember the volume of solution used was 50 cubic centimeters.

Q. Do you know how long you ran it? A. The same as the other experiments, as I recall; the 16 hours at a temperature of 85 degrees.

The Court: If the other witness discovers at any time that his memory is different, it will be perfectly all right with me to interrupt.

Mr. Owen: I will ask Dr. Cardwell to speak up without hesitation.

The Court: He nodded, and I wanted to give my approval to that rather than—sometimes, you know, I give a witness fits for coaching, but here it is all right.

Mr. Lyon: But just to clear this up at that point, did you repeat any tests with agitation or with 300 c.c.'s of acid corresponding to the tests you made with the defendant's samples on Table 19? A. I don't remember that we did.

Dr. Cardwell: We did not.

Mr. Owen: Now, Doctor, mention has been made on two or three occasions of the samples taken at the first treatment of the Stella Wilcox well on August 2nd, 1938, three days before the treatment of the same well concerning which you have testified. I will ask you if you made tests of the defendant's acid taken from the defendant's truck at the first treatment of the Stella Wilcox well on August 2nd, 1938? A. I believe that material is referred to in my notes as Samples No. 1 and No. 2, and I did make tests of such material.

Q. Will you refer to your notes and tell the court what tests you made and the results of those tests? A. Sample No. 1 gave a reduction in corrosiveness, with strap iron, of 82 per cent. Sample No. 2, with strap iron, gave a per cent reduction of corrosiveness of 84 per cent.

Q. Did you also test them with other irons? A. We did, with the National Supply Company iron, and the Oil Well Supply Company iron, and the Atha Supply Company iron.

Q. What were the results of those tests? A. With the National Supply Company iron, sample No. 1 gave a reduction in corrosiveness of 81 per cent. Sample No. 2 gave a reduction in corrosiveness of 78 per cent. With the Oil Well Supply Company iron—I shall read whole numbers here, I have the fractional parts of per cents which I shall omit, though,—sample No. 1, 73 per cent. Sample No. 2, 75 per cent. With the Atha Supply Company, sample No. 1, 88 per cent. Sample No. 2, 89 per cent reduction in corrosiveness.

Q. Did you analyze those samples, or either of them to see whether or not they contained copper, lead or iron, and, if so, what were the results? A. We did analyze each of them. Sample No. 1 contained 25 parts per million of copper; 270 parts per million of lead; and 480 parts per million of iron. Sample No. 2 contained 13 parts per million of copper; 250 parts per million of lead; and 480 parts per million of iron.

Q. I suppose the court would like to know, and I would like to have you state for the record, why you did not include the samples from this first Weber well, or, from this Weber treatment, in the tabulations which you have given showing the average corrosiveness of the defendant's treating acids on different pieces of iron? A. Probably,—there was one reason that we did not include that data in our first sets of tables. In the first place, the sample was quite different—I mean, the samples were quite different in appearance from the other samples; and they contained a surprisingly high percentage of copper; and, frankly, at

the time we were very puzzled, and we did not quite see how those samples fitted into the picture, we did not know what might be wrong. We figured that the other samples did represent representative samples, and showed uniformly throughout, but—well, it was for that reason, I think, that we failed to carry through samples 1 and 2 completely in our notes.

The Court: The samples of the acid are from— A. That is of the acid from the oil well.

Mr. Owen: Taken from the defendant's treatment at the Stella Wilcox well on August 2, 1938, three days before the other Stella Wilcox treatment of the same well.

The Court: Samples 1 and 2 were both taken from the same well and same transportation tank, at the same time?

Mr. Owen: Yes, Your Honor.

Mr. Owen: Doctor, did you find any other striking difference between this first Stella Wilcox sample and the other samples, that is, those taken from the second Stella Wilcox treatment, the Zahn and the Crawford treatments? A. Well, the one striking difference, the samples we received had a layer of oil on the samples, samples 1 and 2.

Q. How much oil, would you say? A. Oh, a very appreciable layer. I could tell by referring, probably, to original notes about the proportion of oil, but it was a very appreciable amount, a substantial layer of oil.

Mr. Owen: I will make an explanation at this point and support it by evidence so that Your Honor will keep up with the story. The evidence will show that when that first Stella Wilcox treatment was given the defendant first put in 500 gallons of acid into the well, and then the operator of the well asked him to make the treatment in four stages. There was 1000 gallons of acid. He asked him to make the treatment in four stages of 250 gallons each, so the defendant's truck man pumped back from the well 250 gallons of acid, pumped that back into the tank before these samples were taken, and, of course, in pumping it back into the tank it pumped a certain amount of oil along with it, and that was another reason why the Doctor

thought it would not be fair to rely upon those samples which show a very much higher percentage of inhibition than the ones on which he has relied.

Mr. Lyon: To complete that explanation, Mr. Owen, this Michigan oil contains mercaptans, and if you had some Michigan oil in this acid or long pipe it would inhibit the acid, would it not?

Mr. Owen: I will say in response to that, Mr. Lyon, that you are perfectly free to use uninhibited hydrochloric acid as you buy it commercially in the Michigan oil wells, and if you can get inhibition sufficient to protect those wells due to the presence of the oil and the slight inhibitors, slight amount of inhibitor, there may be in the commercial acid, we won't complain.

Mr. Lyon: I am not asking for that. Just to complete the explanation, you say that the Doctor rejected that sample because it had some oil in it. As a matter of fact, that oil would increase the percentage of inhibition.

Mr. Owen: It would, yes.

Mr. Lyon: That is the point I am getting at.

Mr. Owen: And, that is the fact in every Michigan treatment made by the defendant, that in addition to the inhibitors that are present in its acid when it is put into the well, they have the benefit of this inherent inhibitor which happens to be in the Michigan oil. But, our contention is that that natural inhibitor in the oil is not sufficient for the defendant, or anyone else, to get by with uninhibited acid, and they don't attempt to get by with it.

Mr. Owen: Now, Doctor, I will ask you if you have a table showing the different amounts of copper, lead and iron which you found in defendant's storage acids and also in defendant's truck acids, the samples of which you examined? Have you one of those? A. Yes; I have such a table.

Mr. Owen: This table will be offered as PX 169.

(The table above referred to was thereupon marked PX-169.)

Mr. Owen: I might state, Your Honor, this is merely

a convenient collection of this data so that you won't have to search through a dozen or more different exhibits to find it.

Q. (Mr. Owen): Now, doctor, will you explain what that exhibit shows? A. That exhibit shows the copper, lead and iron content contained in a thousand gallons of defendant's hydrochloric acid samples. The amounts are represented in terms of grams, and also there is represented on the chart the amounts expressed in terms of parts per million of the metal present in the solutions.

Q. In explaining that table, I suggest that you take up, first, the amount of copper in the storage samples and then the amounts of copper found in the truck samples. A. The amount of copper found in the storage acid sample N14B—that is with the storage acid diluted down to 14.5 acid to correspond to the truck sample acids—the amount of copper was 0.72 parts per million, or in each 1000 gallons of the acid solution the amount of copper was 3.1 grams. The same determination for the copper in the sample S14B, which is the south storage tank solution, diluted also to the same strength, was 0.69 parts per million or 3.0 grams in a thousand gallons. Now, the average copper content of the two storage tank acids was 3.05 grams per thousand gallons.

Q. Now, take up the corresponding truck acids. A. The corresponding truck acids are represented by Stella Wilcox sample in which the copper was present in 3.6 parts per million, or 15 grams per 1000 gallons, and in the Zahn acid sample of a corresponding strength, the copper was present 3.1 parts per million or 13 grams per thousand gallons.

Mr. Owen: Now, in this connection, I want to call Your Honor's attention to the fact that this Wilcox treatment and the Zahn treatment must have been made with the same storage acid because the data which I read in Mr. Edwards' deposition this morning indicates that no purchases of storage acid were made between July 24, 1938, and August 27, 1938.

Q. Now, you take up the lead item for those, please. A. The lead found in the storage acid sample N14B was 4.8 parts per million or 21 grams. In sample S14B 4 parts per million or 17 grams. The average of these two samples was 4.4 parts per million or 19 grams of lead in 1000 gallons of storage acid. In the corresponding truck acids, the Stella Wilcox sample had 417 parts per million or 1700 grams per 1000 gallons, and the Zahn acid 435 parts per million or 1800 grams of lead per thousand gallons.

Q. Now, take up the iron item. A. The iron content of the storage acid sample N14B, 13 parts per million or 56 grams; sample S14B 6 parts per million or 26 grams. The average of the two, 9.5 parts per million or 41 grams of iron per one thousand gallons of storage acid. While in the truck acids Stella Wilcox gave iron 473 parts per million or 1900 grams, and the Zahn well gave iron 380 parts per million, or 1500 grams per thousand gallons.

Mr. Owen: Now, before taking up the metal content of the N20B and S20B samples and the Crawford truck samples, I call attention to the fact that according to the testimony of Mr. Edwards, between the date when the Crawford well was treated and the date when the N-20 and S-20 samples were taken, there was one purchase of acid—7,866 gallons, from the General Chemical Company on October 17, 1938.

Q. Now, Doctor, take up these samples N20B and S20B, and the different metals in them, comparing them with the metals found in the Crawford sample? A. Storage acid sample N20B contained 0.17 parts per million of copper, or 0.75 grams. Sample S20B contained 0.26 parts per million, or 1.1 grams. The average of these two is 0.21 parts per million, or 0.92 grams.

The Court: Now, let me see, you are not claiming that these storage samples—you are not claiming that you have got a sample of the exact acid that they treated their well with?

Mr. Owen: No, Your Honor.

The Court: But this shows how their samples ran?

Mr. Owen: That is right.

The Court: Is it the thought that I will draw the conclusion that if that is the way they were running, that is the way they probably were when they treated the well?

Mr. Owen: Yes, Your Honor.

The Court: All right. It is not any exact proof, but it is substantial, in other words.

Mr. Owen: We have shown in the testimony read this morning, of Mr. Edwards, that they had I think six or eight purchases prior to the date of the Crawford treatment all made from the same source, the General Chemical Company.

The Witness: The analysis of the Crawford sample showed a copper content of 4.8 parts per million, or 20 grams. The corresponding data for the other metal constituents of the acids is, the storage acid sample N20B contained 2.6 parts per million of lead, or 11 grams. The sample S20B contained 7.3 parts per million of lead, or 32 grams of lead. Or an average of lead content in these two samples of 5.0 parts per million, or 21 grams. It was found that the lead in the Crawford sample of corresponding acid strength was 53 parts per million, or 220 grams in 1000 gallons.

The analysis for iron showed that in sample N20B, there were 7.0 parts per million or 30 grams. In sample S20B, 9.6 parts per million, or 42 grams. This gives an average iron content of these two samples of 8.3 parts per million, or 36 grams. The iron analysis of the Crawford sample showed 210 parts per million, or 860 grams per 1000 gallons.

Mr. Owen: Now, just to give a resume of this showing on this chart PX-169, Your Honor, it showed that the metals in the acid used in the treatment of the Stella Wilcox well were increased over those found in the storage samples taken at approximately the same time in the following proportions—the Stella Wilcox truck acid had approximately 400 per cent more copper than the storage

acid had; it had about 8,000 per cent more lead in the acid than the storage acid and 4,500 per cent more iron than the storage acid.

And the same data with reference to the Crawford well are that the truck acid contained approximately 2,000 per cent more copper than the storage acid contained; it contained approximately 1,000 per cent more lead than the storage acid; and approximately 2,300 per cent more iron than the storage acid. And those additions took place somewhere between the time when the storage acid was placed in the truck tank and the time when the treatments were made at the wells.

Now, yesterday we introduced quite a large number of charts which I know must have been more or less confusing and perhaps annoying to the court.

The Court: No; they helped me a lot.

Mr. Owen: But in order that the information with reference to the experiments made by Dr. Bartell, in which he added different proportions of metal in different combinations to fifteen per cent C. P. hydrochloric acid may be more accessible and intelligible, I have a chart which has accumulated that information and which I will offer as PX 170.

(The chart above referred to was thereupon marked PX-170.)

The Court: This shows corrosiveness and not inhibitiveness.

Mr. Owen: Well, it shows both. The dark line shows corrosiveness. The upper line is for 15.1 C. P. hydrochloric, which is shown for purposes of comparison to be one hundred per cent corrosive. And then going on down it shows the relative corrosiveness of these different solutions with the different additions, and at the end of the chart—

The Court (interposing): The black lines show corrosiveness?

Mr. Owen: The black line is corrosiveness and the figure at the end of the line is the percentage of reduction of corrosiveness.

The Court: Or inhibition.

Mr. Owen: Yes.

The Court: All right. The black line is the corrosiveness. That is what I first thought.

Mr. Owen: Now, will you explain this chart, Dr. Bartell? A. Black lines are placed on this chart on this scale to show the per cent corrosiveness of the different samples. Now, we have mentioned previously that with the C. P. acid the corrosiveness of that will always be taken as 100 per cent, and the C. P. acid is always used as a blank in making tests of the corrosiveness of other acid solutions. So that the first black line represents a hundred per cent corrosiveness of the C. P. acid. Now, the second line gives the corrosiveness of a solution of 15.1 per cent C. P. acid to which was added 440 parts per million of iron. The corrosiveness of that acid solution was 97 per cent that of the C. P. acid; or, the reduction in corrosiveness brought about by the 440 parts per million of iron in that acid was 3 per cent. These solutions to which I am referring on this chart are numbered. This is No. 16. That solution was referred to yesterday in my testimony in describing the corrosiveness of acid solutions to which have been added different amounts of metals.

Mr. Owen: That is PX-166, Your Honor, Table 18. In other words, the numbers 16, 11, and so forth, on this last chart just produced correspond with the solution numbers in the left-hand column of the chart in evidence as PX-166, Table 18.

The Witness: So, the first solution taken was No. 16 which I have just described, which showed a reduction in corrosiveness of 3 per cent.

The second test was that with solution No. 11 to which was added 320 parts per million of lead to the 15 per cent C. P. hydrochloric acid. That acid was 88 per cent as corrosive as the C. P. acid, or the reduction in corrosiveness was 12 per cent.

The next solution referred to is solution No. 2, to which had been added 3.5 parts per million of copper to

the 15.1 per cent C. P. hydrochloric acid. The corrosiveness of that acid is 67 per cent that of the C. P. acid, or the reduction in corrosiveness is 33 per cent.

The next solution tested was solution No. 30 to which was added 3½ parts per million of copper, plus 300 parts per million of iron. The reduction in corrosiveness in this case, again, was 33 per cent, showing that the 300 parts per million of iron added to the copper in this acid had practically no effect.

The next solution tested was solution No. 26. To the acid was added 3½ parts per million of copper, 320 parts per million of lead. The reduction in corrosiveness in this case was 38 per cent.

Solution No. 68, to which was added 3½ parts per million of copper, 420 parts per million of lead, 440 parts per million of iron—in that experiment the per cent reduction in corrosiveness was 40 per cent.

Now, in none of the samples mentioned so far was there any agitation. The solutions were of 50 c.c.'s in volume, and the metal pieces were as described yesterday, these small strips 1 inch by ⅞ths by ⅛th inch.

The next experiment represented on the chart is an experiment conducted by taking a solution the same as No. 2, containing 3½ parts per million of copper, but agitated. It is 50 c.c. again, and agitated as we described previously. In that case, the corrosiveness was much reduced; it was reduced by 44 per cent.

Q. How does that compare with the same solution in which there was no agitation? A. The solution which was not agitated gave a reduction in corrosiveness of but 33 per cent; so the agitation resulted in an increased reduction in corrosiveness.

Q. Just proceed with your experiments? A. Another experiment was performed, using the composition of solution No. 2, but using 300 cubic centimeters of that solution. Also, the solution was agitated during the test. Otherwise the conditions were the same, that is, the length of time and the temperature. In this case, the corrosiveness was much

less—the reduction of corrosiveness was greater, the reduction being 63 per cent.

Then another experiment was performed in which a solution indicated as solution No. 30 was used, 300 c.c. of that solution was used, and the solution was agitated. That solution contained 3½ parts per million of copper, 300 parts per million of iron. The reduction in corrosiveness shown in that test was 64 per cent.

Now, there is one more test illustrated on this chart, solution No. 68, which we have previously used with a smaller volume of solution, and with no agitation, and we get here 40 per cent reduction in corrosiveness. The solution was one containing 3.5 parts per million of copper, 400 parts per million of lead, and 440 parts per million of iron. Using 300 c.c. of this solution, and agitating it gave a reduction in corrosiveness of 63 per cent.

The Court: It is my understanding that there is no new information given in this chart over that previously given, but that you have assembled out of the information previously given certain data that you thought would be helpful to me and to every one, indicating the picture of this? A. Yes, Your Honor, I believe that is correct.

The Court: You have selected from your previous exhibits all of this—in other words, the preparation of this did not require anything special? A. No, no new data.

Mr. Owen: It is based on the data contained in the previous exhibits. I thought this would be more convenient for you.

The Court: Yes, it is.

Mr. Owen: I have just one more matter, Your Honor. Last evening I asked Dr. Bartell to make a new computation of averages from his Tables I, II, III and IV, PX-154 to 157, inclusive. Have you done that, doctor? A. I have, yes.

Q. Can you tell the court the results and how you arrived at them? A. It was suggested that averages be calculated by taking a summation of all the direct data, as loss in weight for the different samples of acid used with a

given piece of iron, taking the sum of all of those values, the per cent loss in weight; likewise to take the values obtained for corresponding blank acids. This was done. The summation of the per cent loss in weight for all of the oil well samples—I should say truck tank samples—were taken and then the summation of the corresponding blank samples weighed, so as to correspond in number to the truck tank samples, and then the total of these values were used and the reduction, per cent reduction in corrosiveness calculated from the summation of these two sets of values. By using that method, it was found that the average reduction in corrosiveness obtained with the metal strips of strap iron, as described in Table I, was 52 per cent.

Q. How did that compare with your previous figure made up in a different way? A. The values given yesterday, which was the average of the average values of the three oil well samples, was 53. So the values checked to within that extent, the calculation as suggested giving 52 and our method of calculation gives us 53, as the average of averages.

The Court: This latter one is really more accurate, is it not? A. No, Your Honor, I would not think it would be as justified, no.

The Court: Didn't you divide it by the—let's see now, you added all of the results and divided by the total here, the total number of experiments, is that it? A. We did, Your Honor, but it so happens that we had a larger number of samples for one of the oil wells than we did for the others, so, in my opinion, it was not quite as justified as the other method.

The Court: There was a larger—it was a truer average of your samples, but the way you had selected your samples, it made that unfair, doing it that way, and you take care of that unfairness by the first— A. (Interrupting): By the first method, yes.

The Court: In other words, if I was going to get the average weight of people in Detroit and Bay City, and I did not want to weigh them all, if I was going to go by samples,

I ought to select them relatively—if there are 100 times more in Detroit than there are in Bay City, I ought to pick 100 more samples from Detroit than I would in Bay City? A. That would be justified.

The Court: That is the theory that you used in taking care of this— A. (Interrupting): That is in effect the principle that I had in mind at first, since we had three samples from one well, and two samples from the other wells, and I took the average of the averages, yes.

(By Mr. Owen): Now, doing the same thing with your Table No. II, what was the result? A. Doing the same thing with Table No. II, the calculation made as suggested yesterday was 30 per cent; and the average of averages gave 31½ per cent.

Q. Now, will you take up Table No. III and Table No. IV? A. Table No. III by the newer calculation gave 38 per cent, and the value that I gave yesterday was 38.5 per cent. Table No. IV gave by the more recent method of calculation 50 per cent; and by the method reported yesterday 51.5 per cent.

Q. My notes that I made on my copies of these charts yesterday do not correspond with the figures that you have just given for your average of averages. I do not know where the discrepancy is, whether I made a mistake, and I will have to change all of these. A. Let me check back on the chart and my notes. (After checking) Well, I am not certain yesterday but that there was brought in a third method of calculation, that the average of the seven samples was taken on.

Mr. Owen: I will ask you do this, Doctor. During the recess I wish you would ascertain what the original figures were you gave for these averages, and then we will put them in the record. A. That would be very simple. If I were sure which set of figures were given, it is perfectly possible to make either calculation.

The Court: All right.

Mr. Lyon: Frankly, Your Honor, I may be able to arrive at a point here before one o'clock where we can agree

on what the issue is in infringement here, and dispose of any dispute as to the facts. I would like to do that because I would like to submit a clean cut issue to the court, if we could. That is what I am going to try to do. I have in mind what it ought to be, and if I can get an agreement on it, I would like to submit it. As I understand it, Your Honor, the plaintiff's charge of infringement in this case is based on increased amounts of copper and lead which they state they have found in the defendant's acid at the well as compared with the amounts that exist in the storage tank acid. Can we have an understanding to that effect?

Mr. Owen: The charge of infringement is based on the fact that the defendant's treating acids, which it uses in treating oil wells in this district to increase their productiveness, contain substantial portions of copper, lead and iron which they did not contain when those acids were purchased by the defendant, and as those acids stand in the defendant's storage tanks at Mt. Pleasant. And by "substantial amounts" I have reference to their effectiveness rather than to their quantity in grams or ounces.

Mr. Lyon: I think that answers my first question, Mr. Owen.

Mr. Owen: What we are interested in is the acid as it went into the well, and if that contained substantial amounts of inhibiting materials, that is what we claim to be an infringement, and I don't limit the charge of infringement to the portions of the inhibiting materials that were added or which accumulated in transit. I think we must take the acid as it is used in the wells and consider whether or not at that time it was inhibited acid within the meaning of this patent.

The Court: When it starts down?

Mr. Owen: When it starts down.

Mr. Lyon: As I understand it, those materials which you say are the added inhibitors are the copper, and the lead, and the iron which you find in the well acid which you didn't find in the tank acid. I just want to know if those are the inhibitors that you are charging to be an infringement.

Mr. Owen: I wouldn't limit myself in such a way as to exclude other inhibitors that might be present. Those are the ones our expert found and we have shown that the amounts in which they were found are in themselves quite effective, but if the acids contain other inhibitors—

The Court (interposing): You haven't shown anything about the results they obtained in the well.

Mr. Owen: All we can do at this time is to show what the acids were that went into the wells, and how much they were inhibited as compared with C. P. acid.

Mr. Lyon: Can I put it this way: Do you claim now or contend that there is any other added inhibitor in the defendant's well acid other than these added amounts of copper, lead and iron?

Mr. Owen: I don't think we are so much concerned with whether they were added or not, as we are with whether they were present or not when the acid was used.

The Court: As I understand the question, do you claim there was anything present except this copper, lead and iron?

Mr. Owen: Apparently there were some minor inhibitors present in small amounts.

The Court: That you claim? You had it to analyze all these months.

Mr. Owen: Yes.

The Court: Why don't you analyze it and claim it, if there is anything more than that copper and lead and iron that I have heard about that is in there? You have had the samples there.

Mr. Owen: Well, I don't see that the burden is on the plaintiff to show every different thing that might be in that acid that caused it to be inhibited. I think the question is whether or not the acid is inhibited, and not how it is inhibited or what causes it to be.

The Court: But I have no reason to think it is inhibited by any result obtained by the thing down in the well. The only reason I have got to think it is inhibited is because it has got copper, lead and iron in it. That is the only thing in the world that makes me think it is inhibited.

Mr. Owen: Well, you also have Dr. Bartell's tests, the results of his tests of the acid as it came from the defendant's truck tanks. Those were the first tests he made, and when he reached the conclusion that there were some things in that acid which caused it to be inhibited, then he made his analyses to find out what it was as far as he could, and he found that they did contain copper, lead and iron, and he has reported that data.

The Court: In other words, it is your contention that you could show it was inhibited and not bother what the cause of the inhibition was.

Mr. Owen: I think we could have done that.

The Court: You could put a piece of iron down in there and show it didn't eat it, and—

Mr. Owen (interposing): I think we could have done that, and it would be—the burden would then be on the defendants to show how the inhibitor got in there and what it was, and whether they were responsible.

The Court: As you claim the patent is so broad that it covers anything that inhibits.

Mr. Owen: That is true. Our patent is not limited to any specific type of inhibitor.

The Court: Or any particular type of metal.

Mr. Owen: No. No; that is true.

The Court: All right.

Mr. Lyon: I would like to go ahead.

Mr. Owen: It is confined to an inhibitor which will prevent corrosion of iron by hydrochloric acid.

The Court: He says he is satisfied with your answer.

CROSS EXAMINATION

Q. (By Mr. Lyon): Now, will you please refer to Exhibit 169, which is this summary of copper, lead and iron contained in grams per thousand gallons of defendant's hydrochloric acid samples, and convert those values into per cents so that we can compare them with the 1 to 5 per cent by weight called for in the specification of the patent in suit? A. Yes.

Q. I do not care about the storage acids. That will take too long. Just take the truck acids and convert them into per cent, so that I can compare them with the statement commencing at line 86, page 1 of the patent, reading "1 to 5 per cent thereof, based upon the weight of the solution." A. The values would be for the Stella Wilcox samples, 3.6 parts per million of copper, 0.00036 per cent. For the Zahn, 3.1 parts per million, would be 0.00031 per cent. For the lead in the Stella Wilcox, 0.04017 per cent. For the lead in the Zahn, 0.0435 per cent. For the iron in the Stella Wilcox, 0.0473 per cent. For the Zahn, 0.0380 per cent. And, the values for the Crawford would be; for copper, 0.00048 per cent; for the lead 0.0053 per cent; and for the iron, 0.0210 per cent.

Q. As I understand you, Dr. Bartell, you determined the per cent of inhibition for the specific formula appearing at page 2 of the patent in suit commencing at line 70 through to the end of the sentence on line 88, but in that test you employed no agitation; is that correct? A. That is correct.

Q. Now, it is reasonable to suppose, is it not, or you would expect that with agitation in that test you would get a higher percentage of inhibition than 97 per cent? A. We didn't perform the experiment. I would prefer not to speculate.

Q. With the defendant's samples where you had inhibitors present, you testified yesterday that agitation increased the percentage of inhibition. A. It did.

Q. Have you any reason to think that that wouldn't be true with the formula of the patent? A. I have no reason to base such an opinion.

Q. All right. Then the only thing we could do is compare the tests on the defendant's samples that had no agitation with the sample of the patent that had no agitation. I want you to tell me how many times as corrosive you found the defendant's samples to be than the specific sample of the patent formula, basing the comparison on the tests without agitation? A. It may take me a few moments to assemble the information.

Q. I wish you would, because that is the effect of your testimony and I want to understand your testimony today, if I can, and see if we can shorten this proceeding. Of course, I want you to confine yourself to experiments with the same kind of metal as you employed in making the experiment from the formula of the patent in suit. A. We haven't available the data with which I can make an exact calculation that you have asked for.

Q. Why not? A. I have not the data with me obtained with the arsenic sample that was referred to.

Q. You gave me a figure of 97 per cent. A. I did.

Q. Inhibited, didn't you? A. That was the reduction in corrosiveness, but I haven't the experimental data from which that was calculated.

Q. What is it that you don't know? A. I do not know the original amount of weight of the metal, nor the loss of weight, nor the per cent loss in weight.

Q. I don't need that. Do you know what type of metal that experiment was made on? I mean I don't need it for this particular question? A. It was made with a metal similar to that that we have stated in the other experiments.

Q. Which one? You have a lot of different metals? A. Strap iron. But I do not know which series.

Q. You don't know which series? A. Of strap iron we used in that particular test.

Q. Your strap iron figure is shown in Table No. I, is it not? A. Some of them are, yes.

Q. Well, now,—well, all of them on Table No. I, Series D and B, are the only two on there, aren't they? A. That is right.

Q. And they all use strap iron. Now, then, you found that the Stella Wilcox—the samples from the Stella Wilcox well were—what is the difference between Series D and Series B? A. As I explained previously the series came from different lots or pieces of strap iron.

Q. All right. Well, let us compare it with Series D, in the first place. You say that these tests on Table I had no agitation? A. That is right.

Q. All right. Now, we will compare your 97 per cent figure with your 47 per cent figure here, the first figure under the title, "Per Cent Reduction in Corrosion" in Series D. How many more times is defendant's acid as there shows corrosive than the patent sample which you say was 97 per cent inhibited? You divide 3 into 47, don't you? A. The corrosiveness of the plaintiff's sample would be represented by 3 into 53. The rate of corrosion of the one would be about 17 times that of the other.

Q. All right. Now, let us take the next value on that column 18, that is also 17, for all practical purposes, is it not? A. It would be close to that.

Q. 17 times. Now, let us go down to Series B on the Stella Wilcox well. On the basis of Series B how many more times corrosive is the defendant's well acid that was used on the Stella Wilcox well than the acid of the patent, the specific example from the patent you have given? A. Well, on that basis, it would be about 19.

Q. Sample 6 in Table I, the value 43 would also be approximately 19 times as corrosive? A. That would be 19 times, yes.

Q. And so would the average, then, without asking that. A. As a matter of fact, the one I gave before would be a little less than 19 in round numbers; it is close to 19.

Q. And so would the answer be from the sample from the Zahn well, which is value 42? A. In that neighborhood.

Mr. Lyon: Now, I would ask, Your Honor, is the plaintiff willing to concede, to stand on the results as shown from these tests, samples from the Stella Wilcox and the Zahn wells as typical and representing the results of the defendant's practice? And will it concede that the defendant's well acid is from 17 and 19 times as corrosive as an acid, or formula corresponding to that, commencing at line 74 through the sentence ending at line 79, on page 2 of the patent in suit?

Mr. Owen: We will not make such a concession for the reason that these tests made by Dr. Bartell are laboratory tests which were conducted for the purpose of showing how

much the defendant's acid corroded the iron in laboratory tests as against commercially pure acid. Now I think Your Honor appreciates that plaintiff is in rather a difficult situation here because we cannot go out and buy an oil well and bring it in here and have it acidized before the court and take that pipe before and after treatment to show the effect of the treatment. We will show, I will state to the court and counsel, by other witnesses, that we have done the next best thing—that we have conducted large scale laboratory tests, but instead of using 50 c.c. or 300 c.c. of acid solutions we have used about 200 gallons of solution. And we have run that solution through an oil well pipe. We have run a series of those tests, both with acids—hydrochloric acid to which these metals have been added in proportions found by Dr. Bartell—and acids which have been produced in a tank built in accordance with the description of defendant's truck tanks, which is in evidence. Those practical tests, as nearly practical tests as we are able to make, show a lower rate of corrosion for the synthetic acids made up to correspond as nearly as possible with the defendant's treating acids; they show a much lower rate of corrosion than resulted from Dr. Bartell's tests. So that I do not want to have counsel proceed or the court to proceed on the theory we are standing alone on Dr. Bartell's tests. Of course it is a simple matter of computation. Counsel doesn't need to fill the record with these computations. Your Honor can make them in your head. It isn't to show one acid is 19 times as corrosive as the other—

Mr. Lyon (Interrupting): I think it is the point.

Mr. Wiles: There is another element counsel has entirely overlooked, and I refer to that part of the specification which has our preferred example, which approaches, at least, one of the best of the inhibitors, but we name a considerable number of other inhibitors as being within the invention, and the use of those will show, and Your Honor will see that the plain intent was to cover inhibitors that are not as effective as the preferred one given, but which materially benefit conditions when you have the acid on iron.

Mr. Lyon: I will have something to say about that when we come to the argument. I am trying now to get the facts before the court.

Mr. Wiles: We are not going to stand on any specific example in the patent, where the patent names a considerable number that differ among themselves.

Mr. Lyon: Dr. Bartell, what per cent by weight of the solution of As_2O_5 is there in the specific example that I have referred to on page 2 of the patent in suit, commencing at line 74? A. (After figuring and conferring with Dr. Cardwell): The best that one can do with that is, of course, an approximate calculation, because to the 4500 pounds of the 15 per cent acid is added 2 gallons of arsenic acid, which changes the thing a little bit, but it would be in the neighborhood of about four tenths of one per cent.

Q. In other words, as far as the range of one to five per cent at line 86 on page 1 of the patent, that formula is a minimum quantity and not a maximum quantity; that is obvious, is it not? A. It is not obvious as to what is meant by the question. If the question simply is to ask whether .4 per cent is closer to 1 per cent than to 5 per cent, the answer is obvious.

Q. Yes. All right, now, referring to the tests with the Detroit company acid, which you stated was 15 per cent inhibited, in the case of strap iron without agitation, how many times as corrosive is that acid than the formula we have just referred to in the patent in suit commencing at line 73 on page 2? A. As I understand the question, the answer obviously is that if the Detroit acid is 15 per cent inhibited it is 85 per cent as active as the C. P. acid, and I understand that the solution referred to as covered by the description of the patent is the one which we reported as giving a reduction in corrosiveness of 97 per cent. Hence that acid would show a corrosiveness of 3 per cent that of the C. P. acid. So, on that basis, the acid showing 85 per cent corrosion would be about 28 times as active as one showing 3 per cent corrosion.

Q. Now, as I understand you, the plaintiff did not

furnish you with a specimen of its inhibited acid that it employs commercially under the patent in suit, and you have made no tests of any such specimen; is that correct? A. I have made no tests of the plaintiff's acid.

Q. Well, I show you a copy of the plaintiff's publication entitled, "The Acidizer" for April, 1939, "Importance of addition agents in acidizing," and call your attention to the table, "Comparative value of inhibitors," appearing on page 2, together with the statement "Per cent of effectiveness of several ordinary inhibitors for prevention of corrosion of steel as compared with 99 per cent results obtained from the use of Dowell's inhibitor." Now, on the basis that the plaintiff's acid of the patent in suit is inhibited to the extent of 99 per cent, then comparing that with the 47 per cent that you referred to in connection with the defendant's acid from the Zahn and Stella Wilcox wells, the defendant's acid is 53 times as corrosive as the plaintiff's acid, is that not correct? A. The answer to the question as to whether an acid which would show a corrosiveness effect of 53 per cent and another which would show an inhibition of 99, or a corrosiveness of 1 per cent, it is true that the one showing the 53 per cent corrosiveness would be 53 times as active.

Q. Now, you have produced Tables No. I, II, III, IV, VII, VIII, IX, XII, XIII, XIV, XV, XVI—no, or up to XIX, here, which appear to me to be all printed here, and all in order at present, but there seems to be missing Tables V, VI, IX, X, VII and XVIII. I want you to tell me what those other tables are? Do you have copies? A. No, I haven't.

Q. Well, you better tell us what they are first. Doctor, you have found those copies? A. I have found all but one of my tables.

Q. Tell us what they are. Tell us what missing table V is, and what missing table VI is, and so forth? A. I will, as far as I am able to here. Missing table V was simply a summarizing table, giving a summary of the per cent reduction in corrosiveness of table I, II, III, and IV;

and it contained that summary of results with the data obtained with the samples from the three—the truck acids from the three wells, and with the four metal pipes. It was simply a summarizing table.

Q. What about table No. VI? A. Table No. VI was a table with but four entries, and that table gave the percentage composition of the concentrated hydrochloric acid found in the storage tanks, samples N-14-B, N-20-B and S-14-B and S-20-B, together with the average of those concentrations.

Q. What about Table No. IX? A. Table No. IX is another summarizing table. It gives a summary in the reduction of corrosiveness, tests made with the storage tank acids, together with the calculation of the average reduction of corrosiveness for those samples.

Q. And table No. X? A. I am uncertain about my table No. X. The position I have here for No. X is the table I presented with the percentage of reduction in corrosiveness of five commercial hydrochloric acids, the values, the figures that I read into the testimony the other day; but I am not certain that that was the original No. X. In fact, I doubt it. I would like to check back on that.

Q. Now, what about No. XVII? A. XVII was a table I had compiled giving data of the analysis that we made of the samples of Mt. Pleasant water, taken on different dates, and it gave the copper analysis of the water on those six different dates.

Q. Now as I understand it we now have before us all the tests that you made?

The Court: No. X, he doesn't know.

Mr. Lyon: He says he thinks it is the percentage of inhibition of commercial hydrochloric acid. A. I am quite certain it had to do with inhibition. I would like the opportunity to place the proper table there if I can locate it. It apparently hasn't been in my notes since I have been on the stand. I thought my tables were complete when I came on the stand.

Q. When we get No. X now, we will have had reported

here the results of all the work you did on this subject, is that correct? A. Oh, I wouldn't say that is entirely correct. I certainly have done some work that may or may not show up in these particular tables. That would be a pretty broad statement to make.

Q. Have you done any experiments on any of these subjects of any significance in connection with the matters that you have reported here which haven't been presented? A. I believe I am correct in stating that this would represent all of the significant work. I believe it would. I say that with reservation. I may have overlooked something but if I have, I don't recall what it would be, with the possible exception of what may appear on that table X.

Q. Now, you did not determine what effect agitation would have on increasing the percentage of inhibition which you reported for the commercial acids, did you? Commercial raw acids? A. No, we did not have that data.

Q. You didn't determine what effect conducting the experiment with 300 c.c. of acid instead of 50 c.c. of acid would have on the percentages of inhibition that you reported to the commercial raw acids, did you? A. No, I don't think I did.

Q. Your answers to those two questions would be the same as to the samples of defendant's storage acids? A. That is true of both the defendant's storage acids and tank acids.

Q. Now, Doctor, can you tell us the date you did the work which is reflected on the table No. I, the date of the experiment? I wish you would take each one of these tables and give us the date the work was done by you and your associate. A. That is asking for a pretty large order. We will be glad to do it. I couldn't do it without referring to my notes.

Q. Has any of this work been done recently? Any of the work reported in your testimony? A. Yes. Some.

Q. When was the most recent work? A. Work I reported on the agitation.

Q. When was that done? A. Oh, that was done within recent weeks.

Q. How long ago? A. I would have to check to give you the exact dates. Some of it within, I believe, the last three weeks.

Q. Now, these tests you made with the samples from the Crawford well, and the amount of or the per cent of inhibition which you report is more than could be the result of the presence of the copper and lead and iron which you have reported for those samples; isn't that correct? A. I don't know that I have made an analysis of the result from that standpoint.

Q. Well, now, wait a minute. You put a table in here showing that after you got up to a certain point that added amounts of copper or added amounts of lead did not materially affect or increase the inhibition? A. That was with chemically pure acid, yes.

Q. You didn't make these various comparisons as against commercial acids? You made them as against chemically pure acid? A. We used chemically pure acid; yes.

Q. Well, now, you don't think that those results are valid for what the differences in the amount of inhibition and the percentage of inhibition there will be between commercial acids and inhibited acids, as distinguished from chemically pure acid? A. The commercial acid may contain certain impurities which might have a somewhat different effect upon the tests.

Q. Well, can you definitely state in the case of these Zahn and Stella Wilcox samples what part of the percentage of inhibition which you report is in excess of the inhibition that was had by the storage acids from which the well acids or tank acids were derived? Can you state that definitely? A. My answer to that is simply reference to the testimony I have given, obtaining or taking samples of the storage acid, actually making tests with that acid, then actually making tests with the Zahn well acids, gives the comparison to be obtained between the two.

Q. How many tests did you make with the samples of the storage acid to determine the per cent inhibition of

that storage acid? A. Well, we made at least one in every case. Not always as many as in the other case, for the simple reason that we did not have the volume of acid to work with.

Q. I notice, Doctor, that in some of these cases you compare the results of one test with an average of the results of three or four tests? A. Yes.

Q. Now, that is not valid; if the result of the one test is approximately the result of one of the series of tests that you are going to average—that is true, is it not? I will try to pick one out here. Let us look at PX-159. A. Yes, sir.

Q. You report as the average per cent loss in weight, with six trials, with commercially pure hydrochloric acid, a value of 2.53, do you not? A. With the chemically pure hydrochloric acid, yes; we used the data obtained with six different tests.

Q. And one of those individual tests has a value of 2.44, has it not? A. It has, per cent loss in weight, yes, sir.

Q. Will you look at the next item above it, that individual test you made on Sample S-14-B has a value of 2.43, has it not? A. It has, yes, sir.

Q. You report that the relation between the sample S-14-B and the chemically pure hydrochloric acid shows a value of what? Of 4.0, do you not? A. That is right, yes, sir.

Q. Well, there is no such difference between 2.43 and 2.44, is there? A. No, but it must be pointed out that all of the data we had for the S-14-B sample gave a value of 2.43, while we were able to take the average of the number of tests made with the chemically pure acid, and the average value in that case was 2.53.

Q. How do you know that a single experiment that reports a value of 2.43 is not in a relation corresponding to the value of 2.44, one of the tests with the chemically pure acid? A. Throughout we have taken the best data that we could obtain under the conditions, and have made the calculations accordingly. We have presented the data,

that this represents the results with one sample, and we feel justified to use the figures in the calculation.

Q. Now, I want to know within what per cent of accuracy we can accept this work, if it is based on that kind of relations. If you are going to take one value for one acid and six values for another, and derive a percentage, you can't say that is accurate work. A. Our six values certainly shows we did no choosing there to obtain the best values.

Q. I am not accusing you of anything. A. And all we can say about the other is that it was the best value we could obtain under the conditions with the amount of solution we had.

Q. Isn't it just as logical to say that if you could find a sample of the S-14-B acid test that came out 2.14 and a test with the C. P. acid 2.44 that those are the comparisons that should be made rather than add five more of one and none of the other in the form of tests? A. That would not be my opinion. I see no reason why one with a series of data should pick from that series of data some one value that just happened to fit a situation.

Q. In many instances in this work you have used,—you have compared the value of an individual experiment for one material with an average of the values of chemically pure hydrochloric acid tests? A. Not in many places in our work, no.

Q. If you are going to compare one average with another you should have the same number of tests in each of the series that you are averaging, should you not? A. It is well to when one can.

Q. Well, what about on this same sheet, PX-159; you averaged two tests of sample N-20, two tests of sample S-20, and how many tests of hydrochloric acid? A. Well, it just happens there that nine are reported. It happened that many values were available.

Q. Now, in the results that you depend on for your reports and for your calculations are loss in weight per grams of the samples of metal that were suspended in the

various acid solutions, is that correct? A. Loss in weight calculated in grams, yes.

Q. That means you weighed the specimens of metal before and after the experiments? A. That is right.

Q. And if we attribute this reduction in corrosiveness to the action of copper and lead on the assumption that you made yesterday that copper and lead in its inhibiting action would, to some extent, plate out or form a protective coating on the specimen in the metal, would it not? A. Some of the copper and probably some of the lead would tend to deposit on the metal.

Q. Whatever amount of such copper or lead did so deposit would increase the weight of the sample when you weighed it, and increase the apparent reduction in corrosiveness, would it not? Unless you corrected for it? A. But the difference in weight due to such a coating would be exceedingly slight for a given piece of metal, such as the size we used.

Q. Oh, well, did you measure it to determine how much it would be and make a correction for it? A. I haven't made any calculation.

Q. Did you make any correction for it? A. We made no correction for it.

Q. Well, we are dealing here with very small quantities, are we not, in these tests? A. We did go so far as to make this calculation, if I may amplify the answer, that weighing out to the fourth place as we did, the amount of copper or lead would not be detected.

Q. How do you know? A. Well, we know that from the amount of copper we had in solution, for example, and the change in concentration that might have occurred in the solution, that there is not enough copper plating out to be weighable on a piece of that size.

The Court: That is, I thought, if I got the meat of your question, the deposit of lead on there would be just as important in the matter as a deposit of copper.

Mr. Lyon: That is correct.

The Court: I understood the answer to say that the amount of copper would be very small. What about the

lead? A. Such lead as might deposit would not be detected in the weighing to the accuracy of these weights.

Q. How do you know if you haven't tried? A. Well, that is simple enough to make a calculation. Do you have any evidence on that (addressing Dr. Cardwell)?

Dr. Cardwell: You know how much copper there is in the solution, and we know that is beyond the fourth place.

A. Yes; even the total amount there.

Dr. Cardwell: If you plated it all you couldn't weigh it.

Mr. Lyon: I believe you attribute or are willing to attribute the greater reduction in per cent—per cent reduction in corrosiveness of the samples from the Stella Wilcox on August 2nd to the presence of oil in the samples that were delivered to you; is that correct? A. Those are the samples I mentioned this morning?

Q. Yes, I think so, Doctor? A. No, I am not ready to make that admission. I do not know for certain why the bigger difference in the two samples occurred.

Q. Did you analyze that material to see or make any test to determine if it was contaminated with an oil and whether that oil had any inhibiting effect on the acid? A. I don't recall the tests I may have made on that at the time. I don't recall that we had data on that. I do remember that at the time we stopped work temporarily with that sample, and whether we went back to it I don't recall.

Q. Did you make any tests on samples from the Zahn and the Stella Wilcox wells, the other samples, or from the Crawford well, to determine whether or not they were contaminated in any way or with any oil? A. I don't recall that we did.

Q. Based on all results of your work and all that you know about the subject, in your opinion did the well samples from the Stella Wilcox well which you refer to as your sample No. 8, or the well samples from the Zahn well, which you refer to as your Sample 12B, or your sample 5 from the Stella Wilcox well, your sample 6 from the Stella Wilcox well, or your sample 12 from the Zahn well, contain any inhibitor other than the amounts of copper, lead and iron

which you have reported that you didn't find in the storage samples N14B and S14B, N20B and S20B? A. I wouldn't be able to answer that question without very careful study of the figures.

Q. Have you made such a study? A. I don't know that I have made a study that would answer specifically the question you have asked. The question is long enough so I am just a little bit uncertain as to the entire scope of the question.

Mr. Lyon: Well, let's leave that question unanswered until we resume here, and in the meantime you may be able to prepare the answer to it if you will.

Q. The per cent of reduction in corrosiveness you reported for the Crawford well is higher than you could account for because of the presence of the amounts of copper, lead and iron, is that correct? A. I believe it was.

Q. But you have no suggestion as to what it was in those samples that produced that greater percentage reduction in corrosiveness? A. Well, apparently, there is some constituent present other than the metals that gives the greater percentage reduction in corrosiveness.

Q. Did you attempt to determine what that is? A. And I have made no attempt to determine what that might be.

The Court: Well, is oil an inhibitor? A. It has been suggested here, I think by counsel for the defense, that oils do contain certain sulphurous compounds that might have that effect, and, if that is true, I would not want to rule out the possibility of such a constituent being present in the oil.

The Court: That is, oil as oil? A. Oil as oil, but the pure oil I would not expect to have an inhibiting effect.

Mr. Lyon: I call your attention to line 3, page 2 of the patent in suit, Grebe and Sanford, 1,877,504, one of the inhibitors there specifically mentioned is mercaptans, is it not? A. Yes, sir, it does.

Q. That is a sulphur compound? A. That is a sulphur compound, yes, sir.

Q. It is well known that Michigan oils are especially rich, if you want to use the word "rich," in mercaptans? A. I would not say that it is well known, because I did not happen to know it myself, and if that is true I really should have known it, but they may contain mercaptans.

Q. Mercaptans have a very distinctive odor, do they not? A. They do.

Q. Do you know whether they have a pretty distinctive odor that corresponds to the odor of mercaptans? A. I know that some of the oils have a reasonably pungent odor, but I have never happened to associate it with mercaptans.

Mr. Owen:- The witness has found Table X, which was referred to on Saturday, and which relates to the tests that he made with other inhibitors mentioned in the Grebe and Sanford patent. I think the mixup on Saturday came about by reason of the fact that his Table X was confined to his use of 1 per cent of the inhibitor; and I learned that he had made tests with higher proportions, and I wanted him to revise the table, so as to include the higher proportions.

We have both tables here which I will ask the witness to produce, first the original one, and then the revised table.

Mr. Owen: The witness has produced his original Table X, which I will offer as PX-171.

(The table above referred to was thereupon marked PX-171.)

Mr. Owen: Will you explain this table PX-171? A. Table PX-171 contains results on percentage reduction in corrosiveness when some of the materials referred to in the Grebe-Sanford patent were used. The results were obtained using strap iron, of pieces the same size as have previously been described, 1 by 7/8ths by 1/16th inches, in acid solutions of 50 cubic centimeters, and the tests were run for the period of 16 hours. The materials reported in that table are a saturated solution of acridine in 15.1 per cent hydrochloric acid, which gave a reduction in corrosiveness of 41 per cent. 1 per cent solution of aniline in 15.1 per cent

hydrochloric acid gave a reduction in corrosiveness of 34 per cent. A 1 per cent solution of pyridine in 15.1 per cent hydrochloric acid gave a reduction in corrosiveness of 47 per cent. A 1 per cent solution of quinoline with the same concentration of acid gave a reduction in corrosiveness of 84 per cent.

Q. Now, those tests were without agitation, as I understand. A. Those tests were without agitation.

Q. Now, did you make tests of any of these inhibitors using more than the amounts you used in the tests shown in Table X. A. I did.

Q. Will you state what those tests showed, and whether or not you made them at the same time you made the tests in Table X? A. The solutions of three and five per cent which were run were run a few days later than with one per cent solution.

Q. What were the dates? A. Let's see. That is about a year ago.

Q. Now, will you state the results of your tests using higher proportions of inhibitors? A. Using three per cent aniline—

The Court (interposing): Have you got those in a table? A. I have not, Your Honor. I have them simply in my own notes.

Mr. Owen: In the tests shown in this PX-171, the witness used saturated solutions in the case of acridine and a one per cent solution in the case of aniline. That is, he added one per cent of aniline to the fifteen per cent hydrochloric acid, so that the solution contained, the entire solution contained one per cent of aniline and ninety-nine per cent of the acid. Now, the new tests that I am going to ask him about were the same as those shown in the exhibit except that instead of using one per cent of aniline he used three per cent, and I believe also one with five per cent, and the same is true with respect to the pyridine and the quinoline. He did not change the hyrochloric acid solution strength, but he did increase the percentage of inhibitor placed in that solution. Is that clear?

The Court: Yes.

Mr. Owen: Now, will you go on with your answer, Doctor? A. The three per cent solution of aniline in the hydrochloric acid gave a reduction in corrosiveness of 60 per cent.

Mr. Owen: I think I will ask the Doctor to re-tabulate this exhibit PX-171 and to add these.

The Court: If there is going to be only a couple, and nobody has objection, I will just add it right down below in pencil.

Mr. Owen: All right.

The Court: Three per cent. That is what?

Mr. Owen: Reduction in corrosiveness of 60 per cent.

Q. Then with 5% of aniline, what was the result? A. The value was 67% reduction in corrosiveness.

Q. Now, as to the pyridine, did you make other tests with that? A. I did. With the 3% solution of pyridine the reduction in corrosiveness was 60%. And with the 5% solution the reduction in corrosiveness was 65%.

Q. Now as to the quinoline? A. With the quinoline, the 3% solution gave a reduction in corrosiveness of 84%, and the 5% solution a reduction in corrosiveness of 84%. The different concentrations of quinoline gave practically the same value in reduction of corrosiveness.

Q. Referring now to the five commercial acids which you purchased and tested, do you recall when you purchased those acids? A. It was approximately in June of '39. It was close to June of '39.

Q. And what did you order? A. I ordered from each of the companies which have been mentioned, a gallon of their commercial acid.

Mr. Owen: Now, during Saturday's session the court asked for the dates of the different samples.

The Court: If I remember my own mind—I recognized it was all in the record—what I was suggesting was that somebody that had time make a little tabulation of something that I could put my eyes on. You talked about analyzing these different things. Something I could put my eyes on so I can place them properly in the picture.

Mr. Owen: We will be glad to do that.

The Court: All right.

Mr. Owen: I think it might be convenient if we prepared a tabulation showing the dates when the defendant replenished its storage tanks and the dates when these well treatments were made, and the dates when the storage samples were taken.

The Court: And the samples taken out of the transportation tank.

Mr. Owen: Yes. We will do that.

The Court: I dare say it is in the record that we had in mind to get. This other was just an added thought. Now, you have got it all in the record, but I doubt if any of you could exhibit to me right now, although in the record, and if you could I would have it this afternoon if I wanted to look at that, and have it in mind. I would just like to see on one page a picture of what we are talking about.

Mr. Owen: We will do that.

Mr. Owen: Do you wish to make a correction as to the date when you performed those experiments that you were just testifying about? A. Yes, I would like to. The question was asked as to the date that these experiments were performed, and in checking carefully I find that they were all performed the latter part of June or the first of July, 1941.

The Court: That includes the one originally shown in typewriting on this sheet PX-171? A. It does, Your Honor.

The Court: And these with the increased percentages? A. That is right. They were all performed within a period of some two weeks or so, the higher concentration ones. They probably started in the latter part of June, perhaps the last week in June, something like that. I haven't the exact date that they were started, but it was during the present summer.

By Mr. Lyon:

Q. Doctor, now have you run any other tests? Are you sure you haven't run any other tests on the subject of

this inhibitor patent in addition to those you have brought into this case? A. In addition to the data that was presented this morning, is that your question?

Q. Including that. Including all the data that you have brought in either this morning or any other morning, are you sure there are no other tests you have made on the subject? A. We probably have made other tests.

Q. Well, where is the data on them? A. They are not included here because the work on that in my opinion was not complete.

Q. Well, have you ever tested any samples delivered to you by any representative of the plaintiff and said to be samples from the defendant's operations, other than the samples from the particular wells that are mentioned in the reports that you have already presented? A. Yes, I do recall one other sample.

Q. I believe you did mention a well that you tested? A. I mentioned a well and at least two or more samples from that well.

Q. Those are all the samples you ever had submitted to you to test say for inhibitors? A. So far as I recall no samples have been submitted to us other than from the wells already mentioned, including at least another well.

Q. Were any samples ever delivered to you by the defendants purporting to be samples from the defendant's operation taken in Kansas? A. I believe not.

Mr. Lyon: It is not clear on the record, Your Honor. Perhaps we can clear this up. Plaintiff, I believe, has made some statements as to whether or not they procured other samples from the defendant's operations around the country, or delivered other samples, and I am informed that many samples have been furnished to plaintiff, and I may be wrong about it. I don't know it of my own knowledge. I only know what is told me, and I would like to know that. I would like to know if they had it tested by this witness, because there is some issue here or may be some issue as to how far the court would treat particular individual instances as representative, and Your Honor has already seen

there is considerable variation, even in the materials presented to you now.

Mr. Conner: This suit was filed on June 15, 1939. Before we filed the suit we had procured all the samples that we are now relying on, except such samples as defendant gave us during the taking of depositions. Now, the intimation made by Mr. Lyon, the record is clear. We have obtained samples of a few in Kansas, and a few in Texas, but those samples were all obtained after this suit was filed, merely for our own benefit to substantiate that what they were doing in Michigan was also taking place elsewhere.

Mr. Lyon: Let's have no mistake on it. Because we will call a witness on this.

Mr. Conner: And the later samples were never submitted to Dr. Bartell at all. The only samples he obtained were samples taken in this state in the months of August and September of 1938, and one sample taken in April of 1939, all prior to filing this suit June 15th. Defendant's intimation here is we have taken samples all over the country and picked Michigan where the infringement is. That is not true, Your Honor. The only samples we obtained after the suit was filed were obtained in Texas and Kansas.

Mr. Lyon: Mr. Conner, just so there will be no question of inadvertence in your statement, I want to have it definitely understood, because I plan to call a witness on the subject. Are you stating that numerous samples from the defendant's operations taken in Oklahoma and Kansas in the years 1936 and 1937 were not delivered to and received by the plaintiff?

Mr. Conner: No, I am speaking only of what I know. I wasn't with the plaintiff company until the first day of 1938. What transpired before then, I wasn't responsible for and do not have. I am speaking and saying it was my duty and job to obtain the samples for this lawsuit. I personally did not take them; the boys brought them in to me. Samples may have been obtained prior to 1938. I don't know.

Mr. Lyon: That is what I am bringing out. Counsel says there were no samples; now he says he doesn't know.

Mr. Owen: There is one other, the Knight well, that I spoke of the other day.

Mr. Conner: I mentioned it.

Mr. Owen: That is going to be referred to in connection with the other patent.

The Court: Well, with that—it is my understanding that all the samples which you ever gave to the doctor, the samples taken prior to the starting of this lawsuit, are then accounted for,—

Mr. Owen: That is all that I know anything about, Your Honor.

The Court: I am satisfied that that is so.

Mr. Owen: No, I will have to apologize to you on that. There was another sample taken—another storage sample—taken when, Mr. Conner?

Mr. Conner: Some time in April, as I recall, of 1939, prior to the filing of the suit.

Mr. Owen: I think that storage sample was delivered to Dr. Bartell, and I think he analyzed it.

Mr. Lyon: Did he make any tests on it?

Mr. Owen: No different from the others.

Mr. Lyon: Did he make any tests on it?

Mr. Owen: You will have to ask him about that.

Mr. Lyon: What I am trying to do is to get all of this work in here, on Your Honor's theory that all of it should be in here.

The Court: I knew that you would, and I was trying to—I know these things are confusing to me, and I think possibly they might be to Dr. Bartell and everybody else, so I was letting counsel try to refresh the doctor's memory about it so that we could get the facts out.

Mr. Owen: My recollection is now as to the reason we did not include those—that later storage sample, was because it was taken just about the time the Knight well was treated, and I think it will be referred to in connection with the Knight well; but if counsel wants to get the information out now, I have no objection to it.

Mr. Conner: The Knight well was treated April 24, and the storage sample was taken April 26, and we were not relying on the Knight well, so we didn't include the storage sample.

Q. Well, did the plaintiff ever furnish you or did you ever obtain in any way any sample of any of the inhibitors that may be used by the plaintiff? A. I don't recall whether plaintiff has furnished us with any of their inhibitor.

Q. Well, did you obtain it in any other way? A. Oh, yes. We obtained them in other ways. Naturally we would have some of them in stock in our own laboratory, and some I obtained from supply houses, such as Eastman.

Q. Now, you brought in a—just strike that out. You don't have any means of knowing what inhibitors plaintiff has used or is using in its acid? A. I don't believe I have any direct information covering that point.

Q. What do you mean by direct information? Do you have any indirect? A. Not other than hearsay. I may have heard it suggested plaintiff is using arsenic or something of that sort, but specifically, no, I have no specific information.

Q. Do you find anywhere in the Grebe-Sanford patent in suit, No. 1,877,504, any direction or statement as to what amount of the specific inhibitor mentioned in that patent shall be used, other than the amount of arsenic compound? A. I don't remember any such directions, no, other than for the specific example of arsenic.

Q. There is no teaching in the patent or no specification or quantitative figure given as to how much of the other inhibitors mentioned therein may or should be used, isn't that correct? A. I don't believe any mention is made of the amounts of other inhibitors which may be used.

Q. Is there any mention in the patent as to— A. (Interposing) Other than—I will qualify that—in Claim 1 the statement is made that an aqueous hydrochloric acid solution may be used to which has been added "a relatively small amount of an agent capable of inhibiting action of the acid upon metals."

Q. Now, what is your understanding of what "relatively" refers to. It says "relatively small." It is small relative to what? A. It might mean anything, depending upon the system one was working with. Working with the substances such as we normally work with in surface chemistry a relatively small amount might mean as small as one part per million.

Q. I am not asking you what it might mean. I am asking you what it does mean? A. That is what it does mean to me.

Q. It means how many parts in a million? A. Oh, it might be one or a fractional part.

Q. I am not asking you what it might mean. I am asking you is there any definite meaning to this phrase that you called attention to. If so, give it to us. A. Well, relatively small amounts certainly would hardly be taken to indicate more than ten per cent.

Q. What makes you think so? A. Well, simply my judgment would indicate that relatively small means exactly what it says, relatively small.

Q. Does it include up to ten per cent? A. I wouldn't expect it to, as I mentioned, anything like that, or five per cent.

Q. What is the basic figure to which this word relatively refers? What is the practice which it is distinguishing from, do you know? Is it identified in the patent? A. The patent refers specifically to inhibition and the main designation is that a relatively small amount of material may be added to produce inhibition and the inhibition effects would tend to be the measure of the thing that one is after.

Q. Is that the best answer that you can make to my question? A. Well, the answer to the question is that to me the term "relative" would represent a comparatively great leeway in the selection of compounds and naturally compounds with different properties might require quite different amounts to bring about a given effect.

Q. I am asking you to what should this word "rela-

tively small amount," or these words "relatively small amount" be distinguished. What is the practice which these words are used to distinguish from? A. Well, the word "relative" as used in this particular patent is written for one reasonably skilled in the art to interpret.

Q. You have to know the prior art in order to be able to interpret it, is that your answer? A. No, not necessarily. I refer to the art of chemistry, surface chemistry.

Q. Now, does commercial hydrochloric acid as determined by your test contain relatively small amounts of copper and lead? A. It contains small amounts of copper and lead.

Q. Relatively small amounts? A. Yes, they are relatively small amounts.

Q. Now, Doctor, let us take mercaptans. They are mentioned as inhibitors in line 3, page 2 of this patent. A. Yes.

Q. Does this patent tell you how much mercaptans to employ in order to constitute adding a relatively small amount of an agent capable of inhibiting, and so forth? A. The patent does not tell what amounts to use.

Q. What? A. The patent does not state specifically the amounts to use, other than a relatively small amount.

Q. Is that the extent of the definiteness of the patent, as to how much of these inhibitors to use, other than the specific formula given in connection with the arsenic compounds, and the 1 to 5 per cent statement at line 86 on page 1? A. The statement is made that other inhibitors may be used, and it specifies the reference to the organic sulphur compounds, such as mercaptans. It does not refer to the definite amount which should be used.

Q. Well, does it tell you how much you are to inhibit the acid, distinguishing now from the quantity of inhibitor to be added, we are now referring to the effect of the inhibitor, and, does it tell you what the magnitude of the effect is to be? A. It refers to an inhibitor which will decrease the danger of damaging the metal portions of the well.

Q. Does it say how much? A. It does not say how much.

Q. Doesn't it tell you the amount of the inhibitor, how much to inhibit this acid, and doesn't it tell you by the effect wanted as to how much you should inhibit the acid—is that your testimony? A. The last part of that question, yes, it does refer to the effect desired.

Q. Well, does it give you a definite measure of the effect that is to be accomplished? A. Enough so that there will not be damage to the casing, for example; and beyond that, there are no specific directions or specifications that I can recall.

Q. Does it say preclude any damage to the casing, enough to preclude any damage to the casing or pipe? A. Well, in my opinion it refers to making use of the acid practically so that the—well, it is my understanding, and as repeatedly has been indicated, that the non-inhibited acid will have a much greater action on the metal parts of the well equipment; while the use of inhibitors, such as these mentioned, prevents damaging of the casing to the extent certainly of making the operation practical.

Q. Well, what I am getting at, does the patent contain any criterion as to how much the acid shall be inhibited? If so, what is the criterion given in the patent? A. It gives one example of the use of the arsenic compounds and states the amounts of the arsenic compound that can be used.

Q. And in your test with 50 c.c. of acid on the specimen of strap iron without agitation that was 97%? A. That is right. That is per cent inhibition.

Q. Does it give any other criteria or any other measure except that? A. Well, the one to which I have previously referred. An effect which will prevent the danger of damaging the casing.

Q. Doesn't it say how much it protects the casing or pipe in that? Does the patent say? A. Well, there is this statement—"In actual practice this method has never been generally adopted due to the fact that the acid"—and that

refers to uninhibited acid—"attacks metallic casing, pump and so forth, about as actively as the rock." And so the implication would be, certainly, that these inhibitors will so inhibit that the action on the casing certainly will be far less than that indicated by the statement I have just read.

Q. Have you made any test to determine whether or not uninhibited raw commercial hydrochloric acid will attack well pipe about as fast as it will attack lime formation? You know that isn't true, don't you? A. I have made no test to get a comparison.

Q. You know it isn't so, don't you, as a chemist? A. I wouldn't go that far to make that statement.

Q. You wouldn't? You made ordinary tests of pouring hydrochloric acid on calcium carbonate or lime. Every chemist does that in high school chemistry. A. But more may be implied in this case. The limestone referred to perhaps is the rock material within the earth formation and it may be that the acid cannot readily get at that material so as to react as rapidly as it would if the material were in a beaker right in contact with the acid. But the acid must get to the limestone before it will react.

Q. Have you computed in thousandths of an inch how deep the corrosion of acid took place in the experiments that you have made? So you can just give us an idea of what it is. A. I haven't made such computations.

Q. Those pieces you used were how thick? A. About an eighth of an inch.

Q. And it is true, is it not, that the greatest corrosion in any of your experiments that you got was less than a thousandth of an inch in 16 hours? A. Well, I couldn't give you exact value but it was nothing approaching the eighth inch depth.

Q. Why can't you give me the exact figures? You can compute it right off your papers, can't you? A. Assuming the value were around 4% loss in weight would indicate—

Q. (Interposing) On all sides. A. (Continuing) —would indicate that there had not been in those tests a

great depth of penetration, unless by chance the penetration should have been in spots or something of that sort.

Q. Well, I am assuming you get an average penetration. You can see offhand it is of the order of less than a thousandth of an inch, isn't it, from the figures you have just referred to. A. Well, I wouldn't say a thousandth of an inch.

Q. Well, you better calculate it then. It won't take you but just a second. You know the size of the test piece and you can assume the maximum four per cent loss, and figure the area of the sample and tell me what the depth of corrosion would be. I can add one thing to help the doctor, remembering that the penetration is from both sides, I think you will find it is two per cent of one-eighth. A. No, it is not as simple as that.

Q. Did you make the calculation, doctor? A. Yes, I did. Using certain assumptions that may or may not—well, that would not be strictly correct, of course, making the assumption that all the loss comes from the side of the plate, which, of course, isn't quite true, but assuming that it did, and assume that the change in thickness was uniform of the plate, the total loss of iron would be expressed in something like five thousandths of an inch.

Q. Now, then, that means on the same assumption two and one-half thousandths on each side, does it not? A. Yes, calculated on that assumption the loss from each side would be in the neighborhood of as you say two and one-half thousandths.

The Court: And inasmuch as there would also be a layer around the edges it would really be a little less than the figures you have given? A. Slightly less, provided the action were uniform throughout, all over the surface.

The Court: And if you applied the loss it would come at the ends and side of the narrow strip running around it, to the two wide sides, as I understand it? A. Yes.

Mr. Lyon: Well, now, you do not find in this Grebe and Sanford patent in suit any definition of the extent to which the acid is to be inhibited, either measured in the

amount of inhibitor used or measured in effect to be accomplished, other than what you have already stated? A. I believe that is right.

Q. Why haven't you mentioned the phrases used in line 15, page 2, where it says, "And such strength of acid, the corrosive action thereof upon metals, particularly iron or steel, can be largely or substantially inhibited"? A. Well, that is a further indication of the results.

Q. Is that a definite indication? A. Which would be expected.

Q. Is that a definite indication, anything definite about it? A. The word "can" appears, "with such strength of acid, the corrosive action there upon metals, particularly iron or steel, can be largely or substantially inhibited by adding thereto a relatively small amount of an arsenic compound or other inhibiting agent."

Q. Well, now, what does "largely" or "substantially" accomplish here? Does it give us any definite quantitative measure or effect that is to be accomplished? A. Well, I would feel that the implication is to the fact—is to the statement that I made in my earlier answers, that corrosive action can be largely or substantially inhibited, to the extent that the process is made practical the casing is protected.

Q. I want to add to that the sentence commencing at line 25 on page 2, which reads,

(Reading): "Due to the presence of the inhibitor there will be no substantial attack upon the pump tube, or upon the well casing."

Isn't it true that there is no quantitative indication or extent of the inhibition called for by this patent except that it shall be such that there will be no substantial attack, or, to put it the other way, that the acid is largely or substantially inhibited? A. Yes, to a degree, but it is assumed that the uninhibited acid will give what would be referred to as a substantial attack, so the implication is that one must compare the attack with the non-inhibited acid with that of the inhibited acid.

Q. Now, let us assume that we have chemically pure acid, which has the maximum amount of corrosive effect; and, let us assume that we have a completely inhibited acid, now, does this patent tell you at what point intermediate to those two you will be—on one side—accomplishing what is called for by that patent, and on the other side not reaching that accomplishment? A. Not in terms of quantitative figures.

Q. Well, the only terms that exist for consideration are these terms "largely and substantially inhibited," and the term "no substantial attack," so far as the effect of any measurement in this patent is concerned, isn't that true? A. Yes. That is essentially true.

Q. I think I will add to that, to make it complete, the phrase appearing at line 96 on page 2, "without appreciable damage." A. Yes. That term also appears.

Q. Well, now, taking all together these terms, which I understand are, first, the phrase at line 15 on page 2 reading "can be largely or substantially inhibited," and next the phrase at line 26 on page 2 reading "no substantial attack," and the next and finally the phrase at line 96 on page 2 reading "without appreciable damage," will you tell me at what per cent of corrosion or inhibition, either one, lying between chemically pure acid and one hundred per cent inhibited acid marks the distinction between practicing this patent and not practicing the patent? A. I can't tell you that.

Q. Why not? A. I do not know.

Q. Can't you tell from the patent? A. But I have been asked for a specific value and my experience is not such that I could give you a specific value.

Q. You cannot find that value in this patent; is that correct? A. No, the value is not given in the patent.

Q. You are not willing to subscribe to the proposition that the phrases "largely or substantially inhibited" and the other phrases connote an acid which has been inhibited to the extent advertised by the plaintiff, to-wit, 99 per cent, or the extent you found with the arsenic formula, to-wit, 97

per cent or thereabouts? A. The question is put in the negative there somehow. I would like to answer it by stating that I am willing to subscribe—if you will read the question once more, I will try and answer it.

(The question was repeated by the reporter and the question in writing was handed to the witness.)

A. (After examining the question): I would be willing to subscribe to the phrase "largely or substantially inhibited," when used to refer to the plaintiff's acid which has been inhibited to the extent of 97 or 99 per cent.

Q. Would you be willing to do so as applied to the Detroit Chemical Works acid which when tested with the Atha Supply Company metal gave a per cent of reduction in corrosion of 18.4 per cent? A. I would be willing to state that that acid has been inhibited.

Q. Would you be willing to say it was largely or substantially inhibited? A. It would depend upon whether—I would feel that it would depend somewhat on the purposes to which the acid was to be put.

Q. Well, assume that we are going to use it for acidizing a well in a limestone formation? A. I would say the acid is inhibited, and I would feel that the tests, such as I have described, showing inhibition, might not serve as a sufficient criterion to indicate the extent to which the inhibition would exist in the well.

Q. Now, in order to obtain any meaning for the word "substantial," or "largely," or "appreciably," which are comparative words, as I understand it, it is necessary to know the starting point with which to compare them. Do you agree to that, doctor? A. In general, yes.

Q. Now, what do you understand to be the starting point in the case of the words that we are inquiring about, chemically pure acid or commercial raw acid? A. Well, the only definite yardstick, of course, would be the chemically pure acid.

Q. You do not believe that this patent, in discussing inhibited acid, is intending to go back and use chemically pure acid as a starting point, to the exclusion of commercial

raw acid, do you? A. That would not be my opinion, no.

Q. If we are going to use chemically raw acid as the starting point for this comparison, can you place any limit on the percentage of reduction in corrosion that you would tolerate in such a commercial raw acid? A. I feel that it would be necessary to place some restriction on that, yes.

Q. Does the patent give you any guiding restriction, the patent in suit, the Grebe-Sanford patent? A. Not in terms of quantitative values, no.

Q. How are you going to tell from this patent, if you can tell, what the starting point is that you are to employ for the purposes of comparison in interpreting these terms "largely," "substantially" and "appreciably"? A. I have nothing to add to the statements that I have previously made on the same question.

Q. Well, you mean to say, then, that there is no criterion to that starting point in the patent? A. There is no quantitative scale set up, no.

Q. Now, what we are interested in in the— A. (Interposing) In terms of figures.

Q. What we are interested in when we talk about substantial attack on the pipe or the words "largely" or "substantially" inhibited, is the corrosive effect of the acid in question, are we not? The rate at which it would corrode pipe or steel? A. That is involved. That is involved; yes.

Q. Now, would you say that this patent contained any criterion by which you could state, with respect to the corrosion rate, what was embraced within the terms "largely" or "substantially" or "appreciably" as distinguished from what was excluded by those terms? A. There are many types of experiments or processes in which it would not be possible to set up, perhaps, a simple set of criteria to cover all cases. I have already called attention to the fact that when the system is allowed to remain unagitated one gets a certain type of—certain rate of corrosion, while if the system is agitated somewhat one obtains a different rate of corrosion. If one has a certain ratio of metal to acid one gets a certain rate of corrosion; if the ratio is somewhat

different one obtains a different rate of corrosion. So it is perfectly evident from that statement alone that it would be a little bit difficult to set up a quantitative measure covering this word "substantial inhibition," for these different inhibitors.

Q. Well, now let's compare again the matter that I brought up here the other day. On the basis that the defendant's sample which you tested in a particular manner showed 47 per cent reduction in corrosiveness and the plaintiff's formula of this patent showed 97 per cent under similar conditions, I believe you testified that the defendant's acid was seventeen times as corrosive as the plaintiff's formula. I use the word "plaintiff's formula" to refer to this specific formula in the patent. Now, is there anything in the patent in suit to indicate whether or not one acid is largely or substantially inhibited with respect to the other when that acid is 17 times as corrosive as the other? A. No, there is nothing in the patent referring to that. Neither is there anything in the patent demanding that certain volume relations be observed.

Q. Now, if the plaintiff's—I mean if the specimen of the defendant's acid is 47 per cent reduced in corrosiveness, and you compare it with this Detroit raw commercial acid which is 18 per cent, how many times more corrosive is the Detroit raw commercial acid than the defendant's acid? A. Well, if the reduction in corrosiveness of the one is 47 per cent it means its corrosive effect still is 53 per cent. And if the reduction in corrosiveness of the other is 18 per cent it means that the corrosiveness of it is 82 per cent, so the ratio is 53 to 82.

Q. Which means that the raw commercial acid in question would be one and one-half times as corrosive as the defendant's acid, does it not? A. Approximately that. Not quite.

Q. Well, now, let's apply that to these terms "largely" "substantially" and "appreciably" in this patent. Would you say that the defendant's acid in that case was substantially as corrosive as the raw commercial

acid that I have referred to since it is only one one-half times as corrosive, or would you say it was substantially as corrosive as the formula of this patent in suit since it was 17 times as corrosive? A. To give a complete answer to the question I would want to test the corrosiveness under various conditions.

Q. I am just taking—accepting for the moment that you are going to answer based on these comparative tests—that you testified to, to-wit: That the Detroit raw commercial acid had an 18% reduction in corrosion whereas the defendant's sample had a 47% reduction in corrosion under the same conditions. A. I would say it was substantially more inhibited, yes.

Q. Well, is it substantially like the raw commercial acid with respect to its rate of corrosion or is it substantially like the formula of this patent in suit with reference to its rate of corrosion? A. It might apply to both. The term "substantially" might apply to both.

Q. Might apply to both? Will you please explain what you mean by that? A. May I have the original question read, please?

(Whereupon the question was read by the reporter.)

A. It is rather a difficult sentence to analyze. May I have it once more, please?

(Whereupon the question was again read by the reporter.)

A. I have answered, I believe, that I feel "substantially" would apply in both cases. Can the question be made more specific if that answer is not satisfactory?

Q. Is that the best answer you can give to the question? A. I feel it is a suitable answer.

Q. Well, let's put it this way: Compare it to the raw commercial acid on the one hand and the 97% inhibited acid of the patent in suit on the other hand. As to which is the rate of corrosion of the defendant's sample most comparable? Which is it most substantially like? Is it substantially more like the raw commercial acid or substantially more like the formula of the patent in its corrosion rate?

A. If I understand the question correctly, the truck tank sample with its reduction in corrosiveness of 47%—

Q. (Mr. Lyon interposing): Remember it is only one one-half times as corrosive as the raw commercial acid. Now, isn't it more like that in its corrosion rather than it is like the corrosion rate of something that it is 17 times as corrosive as? A. As to the amount of corrosion which would be caused by these two acids under consideration under which the experiments we are referring to were run, it is true that for a given experiment the truck tank sample would reduce a loss in weight of iron more nearly in amount like the raw commercial acid than of the sample of the defendant's inhibited acid.

Q. Now, as you understand the wording of this patent as a man skilled in the art, would you say the patent includes and covers the use of that 18 per cent Detroit raw commercial acid? A. I would feel it might if it were found that under conditions of operation that Detroit commercial acid produced an effect which made it possible to use it to advantage. May I have the question before I put the period there, if you please, to be sure that I have understood the question?

(Question read.)

Q. I mean by 18 per cent the raw acid has an 18 per cent reduction in corrosiveness as compared with chemically pure acid? A. And my answer is it might.

Q. That it might? A. It might, yes.

Q. I can't get very far with the word "might." A. No.

Q. In your opinion does it or does it not? A. I have just previously stated that under the condition of my experiments it was shown that the acid is inhibited. Now, whether or not that inhibition might be sufficient in practice to make that acid outstandingly better—

Q. What is that term you used? A. Outstanding or substantially or very materially better. As to whether it would be materially better under other sets of conditions would have to be determined by running experiments under

other conditions. My experiments went this far, they showed that acid was inhibited, contained something that served as an inhibitor, and that is as far as that particular set of tests of mine that I described were supposed to go.

Q. Well, now, you have referred to the fact that you would have to determine whether or not that amount of inhibition had a quantitative effect, that is right, isn't it? A. Right.

Q. Now, does this patent tell what this quantitative effect is? A. It doesn't mention it in terms of figures, no.

Q. Does it mention it in any definite terms? A. It implies that the effect must be such as to make the improvement of value.

Q. Of value. Is that all that it claims now; is that all the quantitative indications of this patent on that point signify to you? A. To me the patent signifies exactly what it says in claim 1. "In a method of increasing the output of a well for producing a fluid mineral product such as oil, gas, water or brine, the step which consists in introducing into the well an aqueous hydrochloric acid solution to which has been added a relatively small amount of an agent capable of inhibiting action of the acid upon metals."

Q. Now, why wouldn't that fit any commercial hydrochloric acid which was put down a well for the purpose stated for that commercial hydrochloric acid containing amounts of copper and lead? A. Apparently the patent refers to the use of commercial acid; and apparently the patent refers to the addition to such commercial acid of agents which will produce an inhibiting action.

Q. Do you find that definitely stated in the patent? Do you find that this addition is to be to commercial acid, as distinguished from chemically pure acid? If so, will you please point that distinction out in the patent, or, that statement? A. I do not recall that the word "commercial" is used in respect to use in the patent.

Q. Do you understand from reading this patent that when they speak of an addition of a small amount of an agent capable of inhibiting the acid, that they are speaking

of an addition to commercial acid, or are speaking of any addition to chemically pure acid? A. Well, it would be my interpretation that the patent refers to the addition of such agents to commercial acid.

Q. And, therefore, any inhibiting agents that were present in commercial acid and raw acid as a result of its manufacture would lie outside of the added agents to which the patent refers? A. I would think so, if the manufacture is by a normal process of manufacture.

Q. It is true, is it not, that all raw commercial hydrochloric acid contains some amounts of lead and some amounts of copper? A. I could not say how much.

Q. Don't you believe that to be true? A. Well, all I have examined here have contained some, yes, sir.

Q. Now, then, I want to find out if I can if this patent gives us a starting point with which to compare either the amount of agents that are to be added, by weight, or by effect, and I think you have stated now the first premise in establishing that starting point is that we are to start with raw commercial acid though we are not restricted, or not set back to chemically pure acid. Do you agree on that? A. I would be inclined to, with the proviso that I made in my last answer.

Q. Now, then, how much lead or copper would you allow to exist within that raw commercial acid, and still be within the starting point to which we are referring? A. (after examining a book): To answer that question correctly, I would want to—if a definite criteria is to be set up to cover all time, I would want to know the average composition of practically all commercial acids. The evidence is that the available commercial acids contain a copper content somewhere in the neighborhood of three-tenths of a part per million, when those acids are diluted down to approximately 15 per cent acid.

Q. Now, you say in the "neighborhood." I suppose that is the average figure you have given? A. It would be close to the average, the values I have.

Q. What are the extremes? A. The extremes are as

follows: From .24 up to .37 of copper, parts per million.

Q. Now, do you know whether or not that represents the extremes that would be found in actual commercial acids? A. They happen to be the values in all that I have happened to analyze this way.

Q. You haven't made any study further than that? A. I have not made a study further than that.

Q. Do the handbooks, if you know, contain any data on the percentage of copper and lead which may be expected in commercial hydrochloric acid? A. I don't know of such data.

Q. Have you ever examined them to see? A. No, I haven't. I don't believe you would find it. I don't believe you would find it.

Q. Does the patent in suit give any quantitative figure or quantitative value for the amount of inhibitor or copper or lead that may be allowed within the commercial hydrochloric acid which you say is to represent the starting point for the purpose of comparison in this patent? A. No, it does not.

Q. Then if you were the operator of a well, and you employed a service company to come out and acidize your well. They came out and brought a tankful of acid, and before that acid went down the well you tested the acid to see whether or not it was inhibited in the sense of this patent. What would guide you at that point in saying, "I can use this acid without violating the patent," or, "I must tell this operator he cannot be permitted to put that acid down my well because it will infringe the patent"? What would you have to know and how would you determine it, assuming you had the patent before you and were thoroughly familiar with the wording of the patent? A. May I have that question, please?

(Question read by the reporter.)

A. May I ask a question about the question?

Q. Oh, yes. A. The question was if I were the operator?

Q. Yes? A. Then naturally, if I were the operator, I

would know what I now know, and if I were to examine that acid and found that acid to contain copper, for example, in amounts somewhat greater than the values I have stated, I would have my suspicion that copper had in some way gotten into that acid after having left the manufacturer. Hence, I would be suspicious that that acid might be inhibited.

Q. Well, let's suppose you are just the ordinary oil well operator to whom this patent is directed, and you haven't made the tests that you have? How could you tell then? A. Probably if I were an oil well operator I would take the commercial acid delivered to me.

Q. Well— A. If I were the operator.

Q. I am saying that you have heard that the Dow Company is asserting this patent, and you are liable to be sued if you put any acid down the well that is covered by this patent, and this company that you have employed brings out some acid, and you say, "Wait a minute. I have got this patent here and I have read it. I want to test that acid and see whether it is an infringement of this patent or not." How could you tell? A. I would say you better take that acid to the laboratory and have the chemist investigate that acid and determine whether or not that is inhibited. That would seem the logical thing to do.

Q. Now, you have done that. Would you say that the acid—if you, we will say, found the acid had an 18 per cent reduction in corrosive effect, that that established that the acid was covered by the patent? A. I would be rather suspicious of the acid.

Q. I am not asking about being suspicious. I am asking you would you be able—would that establish, as you read this patent, one skilled in the art, is an infringement of this patent? A. I would feel that it might be.

Q. I am asking just a plain, simple question, and not whether it might be. But as you read the patent, does it or does it not? A. If it would be discovered that an inhibiting agent was deliberately placed in that acid, as it may be, why then I would feel I was infringing.

Q. If it hadn't been deliberately put in there but had just arrived there in the normal manufacture of the acid, would your answer be the opposite? A. I have indicated that by a previous answer. Yes, in normal methods of manufacture without the addition of anything.

Q. How much of the inhibiting agents arriving in the acid only due to its normal method and process of manufacture would you tolerate? Or, if you want to express it in per cents of reduction in corrosion in a raw acid, without saying that it violated this patent, assuming that there was no addition subsequent to the normal manufacture of the acid? A. Well, I would feel that an amount such as was represented by the storage tank acids of the defendants would quite likely indicate a suitable value.

Q. That isn't my question. I am asking you how much greater than that could it be and still be permissible? A. Well, anything greater than that might indicate the presence of an added inhibitor.

Q. I am not asking you what it might indicate. I am asking you, assume that it isn't added in the sense that you are referring to, would you allow any amount of inhibitor in there that was caused by the normal method of manufacture of the acid? A. If it isn't added, it can't get there. My answer would be inclined to be I see no reason why it should.

Q. What do you mean "if it isn't added it can't get there"? A. If more of these metals are present in the truck samples than in the storage tank samples, the metals must have gotten there in some way.

Q. Well, would you allow the use of a raw commercial hydrochloric acid for the purpose of the starting point, which we are interested in, if that acid contained no added inhibiting agent in the sense that you referred to but contained amounts of copper and lead sufficient to reduce the corrosive effect of the acid by 18%? A. I would be very suspicious of an acid that would reduce the corrosiveness to 18%.

Q. I am not asking you would you be suspicious of it,

I am asking you if you would allow it. A. If I were in the position that you have suggested I consider myself and had the responsibility attendant to that position, I would want to check up on it immediately. So in that respect I would not allow it.

Q. Then, as a matter of fact, in order to establish a starting point which is necessary for interpreting this patent here in suit, you cannot do it from the patent itself. You have to go and find the acid and examine its method of manufacture, make tests on it to determine the amounts of copper and iron it contains, and find out its per cents of reduction in corrosiveness rather than reading that and relying on the data that is in the patent in suit, is that correct? A. The patent does not discuss the normal impurities.

Q. Then, as a matter of fact, you couldn't establish the starting point from this patent from the wording of the patent itself? You have to go outside of the wording of this patent and make some other kind of determinations? A. I wouldn't say that because I have indicated that I would feel that it would be perfectly permissible to use commercial acid, assuming no inhibition, but if I found the acid did contain inhibitor, then I would feel that it was time to investigate.

Q. Well, all right. Now, can you get the answer as to those acids from this patent? A. No.

Q. Or have you got to go out and look at something else? A. No, you can't get the answers from that patent. It doesn't tell about the manufacture of hydrochloric acid.

Q. And the point that you have got to ascertain then is whether or not the manufacturer deliberately added an agent that wouldn't get into his acid by its normal method of manufacture, is that the point? A. I think that is the thing one should know, yes.

Q. Now, how are you going to tell whether this copper and lead got into the acid in the normal method of manufacture, or got in there by intention? Do you know enough about the manufacture of commercial hydrochloric acid so

you could go in a plant and tell whether they were deliberately adding copper and lead, or whether the presence of copper and lead was due to the normal operation of the manufacture of the acid? A. I could tell this; I could tell whether or not the copper and lead content was above that of the acid when manufactured, and to answer—

Q. (interposing): We are not talking about that. We are talking about this examination to see whether it has been added or not. What do you mean by added, something that you strictly—the term "added" is something after the acid is finished, or something that was done in the manufacture of the acid? A. I refer to after the acid is finished. Perhaps I didn't answer completely your first question there.

Q. Then you think that the real criterion for this patent and the starting point, so-called, is that this patent covers the deliberate addition of an inhibiting agent to a commercial raw hydrochloric acid where that acid is to be put down an oil well to treat a lime formation, you think that is what the patent covers, irrespective of the amount of acid. I mean irrespective of the amount of inhibitor added, and irrespective of the effect as to the percentage of reduction in corrosion? A. I feel that the patent does call for the addition of material to normally made hydrochloric acid which will lower—which will give an inhibiting effect.

Q. Irrespective of the amount of the added agent, or irrespective to the extent of the lowering of the corrosiveness? A. That is my opinion.

Q. That is your opinion? A. Yes.

Q. Do you find that stated in this patent? A. As to the amounts of material?

Q. Yes. A. Yes, it is.

Q. Isn't the information— A. (Interrupting): It is stated in these words: "The hydrochloric acid solution to which has been added a relatively small amount of an agent capable of inhibiting action of the acid upon metals." That is the statement.

Q. That is to be read, is it not, in the light of the speci-

fication, which refers to largely or substantially inhibited, at line 15, so that there will be no substantial attack, as stated at line 25? A. The claim 1 contains no such word as "substantial." The claim 1 states as I have just indicated, reading the entire claim again, if I may, to have that clear:

"In a method of increasing the output of a well for producing a mineral product such as oil, gas, water or brine, the step which consists in introducing into the well an aqueous hydrochloric acid solution to which has been added a relatively small amount of an agent capable of inhibiting action of the acid upon metals."

Q. All right. Now, how does that claim differ from a raw commercial acid containing small amounts of copper and lead? A. In this way: It says an acid solution, an aqueous hydrochloric acid solution to which has been added a relatively small amount of an agent capable of inhibiting the action.

Q. Well, then, for the difference you depend upon the word "added"? A. Added after manufacture, yes.

Q. Added after manufacture? A. After the normal process of manufacture, that is my understanding of that patent and claim.

Q. And any addition of that kind, no matter how small it is, you think is included and covered by this patent? A. It is covered by claim 1, in my opinion.

Q. But you think the addition must be intentional? A. Well, I would feel that is a matter of law.

Q. I am just asking you to read this patent now. As I understand it you are saying that the difference between this claim, and this patent as represented by this claim, and the starting point just outside of the patent resides entirely in the intentional addition of the inhibitor after it is manufactured? A. I do not think that is a fair statement.

Q. Do you know anything about the defendant's method of operation? A. No, nothing, only—

Q. Have you made any tests on it? A. I know only what I have heard about the method. I have never seen the method carried out.

Q. Have you ever made any tests having any bearing on the defendant's method? A. Why, it—

Q. Other than these that you have produced here? A. I think practically none.

Q. Well, any? A. Well, in considering any preliminary experiments, I think—at the moment I think of practically none. What they might be, they would be in the nature of preliminary experiments, or something of that kind, if we made any; but those are essentially all of the experiments that we have made. The information that we have here was essentially the information we set out to get from our experiments, and which we have presented.

Q. Do you know whether or not the purpose of the lead plate bonded into the defendant's tank is to protect its tanks? A. I think I have heard the statement that they were there for that purpose.

Q. Have you any idea how much longer the defendant's tanks last with the lead plate bonded in there than they do without it? A. I have not.

Q. Can you give us an idea, based on your knowledge of the corrosiveness of the raw hydrochloric acid? A. I couldn't give data that would have much bearing on that point, for the simple reason that I am inclined to believe that information one can obtain concerning normal action, as far as metals are concerned in solutions at the source, will be quite different in solutions of 15 per cent acid, and I have not enough information to hazard a guess as to what the reactions would be in the 15 per cent hydrochloric acid.

Q. You are not in position then to compare the causes for the existence of these small amounts of lead and copper in the well, as it arrives at the well, with respect to whether or not that is incident to the protection of the defendant's tanks? A. I have made no study of that.

Q. Further, in connection with this starting point for patent 1,877,504, what is the difference in corrosiveness of the two ordinary raw commercial hydrochloric acids, and one of ten per cent strength, and one of fifteen per cent strength, or twenty per cent strength? A. I have no data to show on that.

Q. Well, this patent in suit specifies, does it not, that a hydrochloric acid may be used of the strength varying from 5 to 20 per cent? A. It does.

Q. Or more. And, as a matter of fact, would the corrosiveness or, the rate of corrosion of those two strengths of acid, 10 and 20 per cent, vary more than the difference in variation between the defendant's well acid samples that you tested and the raw hydrochloric acid in the defendant's storage tanks? A. I couldn't say. They might.

Q. Well, try to figure it out, will you? A. You can't figure it out offhand.

Q. What. A. You can't figure it out offhand.

Q. Don't you know anything about the difference in the corrosion rate of 20 as compared with 5 and 10 per cent hydrochloric acids? A. No, nor anyone else, without having access to data of some sort with such experiments.

Q. Now, have you made any—just strike that for a moment. In the exhibit that you produced this morning, Plaintiff's Exhibit 171, you report certain tests with acridine, aniline, pyrodine and quinoline. You also reported your tests with arsenic. Didn't you make any tests of the other inhibitors referred to in the Grebe and Sanford patent in suit, commencing at line 87 on page 1? A. Not that we have completed.

Q. Not that you have what? A. Completed.

Q. Have you ever tested the cyanides? A. No, we have not.

Q. Have you ever tested the organic nitrogen bases? A. Well, some of these things we have mentioned are organic nitrogen bases.

Q. How about the phenyl-hydrazine? Have you tested that? A. That is the one that we now have under test.

Q. How about mercaptans? Have you tested those? A. We have tested no mercaptans.

Q. Why not? A. We just haven't.

Q. Don't you know, as a matter of fact, or haven't you been told that that is the inhibiting agent that the

plaintiff uses commercially and has used for some years? A. We have not.

Q. You never asked what inhibitor the plaintiff uses? A. I don't believe I ever did.

Q. Nobody told you that that is what the plaintiff used or asked you to test that? A. No.

Q. To make any comparative tests of that? A. No one has.

Q. Well, who have you contacted in this case? Who gave you your instructions on behalf of the Dow Company, of the work you were to do in this case? A. I think the legal counsel here.

Q. Which one? Any particular one of them? Somebody come and arranged with you to do this work and told you what they wanted you to do? A. They did. And I stated in the first of my testimony the other day we were asked to do two things, and as to whom it was, I think perhaps it was Mr. Conner. I wouldn't be positive, but I think it was Mr. Conner.

Q. Were the arrangements made with you? A. Yes, they were made with me. I was simply asked to make the—

Q. He looks more like the man that made the arrangement with you than anybody else around here, doesn't he? A. I beg your pardon?

Q. He looks more like the man that made the arrangement with you than anybody else around here, doesn't he? A. Well, as I recall, Mr. Conner was present the afternoon I was asked to make those measurements. I don't recall who might have been there. I think others were along. Well, I wouldn't be sure. I think possibly Mr. Chamberlain may or may not have been there. I think he was.

Q. I think that is probably safe, he may or he may not. I think that is pretty safe to say that. We are trying to find out what the possibilities were. We are trying to find out what happened. A. What happened, I was asked to make a test of some solutions. I was given those solutions and asked to make the test that I have already mentioned, sample tests.

Q. That is all you were asked to do? A. That is all I was asked to do.

Q. Did they give you a copy of this Grebe and Sanford patent? A. I don't remember that they did at the time. I have since gotten a copy.

Q. How long have you had a copy? A. Oh, over a couple years.

Q. How did you find out that these tests were pertinent to this patent? A. Well, I suppose from the patent.

Q. How did you know that there was such a patent? A. Well, I suppose the patent was given me, certainly.

Q. Do you remember? When you undertake employment in a case like this to do experimental work and are asked to be an expert witness, don't you know who comes to see you and arranges the matter with you; don't you know what instructions are given you, and what material is handed to you? A. I was not asked to be an expert witness when I was first given the solutions and asked to examine them.

Q. When did you find out you were going to be an expert witness in this case? A. I don't remember. Some time after that.

Q. Have you ever been an expert witness in any other case for the Dow Company? A. I think I have in one.

Q. Have you or haven't you? A. I have.

Q. A patent case? A. It was.

Q. Well, that is the only other one? A. I believe that is right.

Q. Then this isn't so common a thing the Dow Company coming and asking you to testify as an expert for them it didn't make some impression on your mind as to what they wanted and what they wanted it for? A. Just to clarify the issue, I may state the company have asked me to examine things in a referee capacity, which had, so far as I know, no bearing, it did not involve me as an expert witness in the case.

Q. Don't you think it would have been rather an intelligent thing to have done in making these comparisons,

in preparing for testifying in this case, to have asked the plaintiff which one of these inhibitors they were using and make a test of that? A. I don't see that that has any bearing on the point. That has nothing to do with the things I testified about.

Q. How about slug acid? Did you make any tests with that? A. What do you mean by "slug acid" please?

Q. From oil refining. A. No, we made no tests with that.

Q. How about residues from acid sulphite paper manufacture? A. We made no tests of that.

Q. How did you come to pick these particular inhibitors that are mentioned on your Exhibit 171 out of this list and test those and not the others? A. Well, we had those available and those were definite.

Q. What do you mean you had them available? A. In our laboratory, in our chemical laboratory.

Q. You didn't have any mercaptans in your laboratory? A. I am not sure whether we did or not, and what's more, the particular mercaptan isn't indicated. It might have been any one of a number of different things.

Q. What difference does that make? Make any tests on that? A. We could have tried them.

Q. What? A. One could try any one of a number.

Q. I mean do you know whether it makes any difference—the difference between one mercaptan and another? A. I expect it would.

Q. Have you tried it? A. I have not.

Q. Well, now, you have sand blasted all these samples— A. (Witness interposing) We did.

Q. In the case of each test that you reported here the metal was sand blasted, is that right? A. Before testing, yes.

Q. Isn't it true that sand blasting a surface like that greatly increases the area of the surface that is exposed to the liquid? A. It probably would increase it somewhat.

Q. Well, you know it would, don't you? A. It depends on the condition of the surface before it is sand blasted.

Q. Did you make any tests so you can tell us how much the area of those surfaces that were exposed to the acid was increased by the sand blasting? A. No, we made no such tests.

Q. Did you try any tests where the samples were oiled before they were put in the acid? A. I don't believe we did. I don't remember such a test. I don't know why I'd do it.

Q. You didn't try? A. So far as I remember, we didn't try.

Q. True, isn't it, in order to corrode a steel surface the acid must wet the surface? A. It must get to the surface.

Q. It must wet it, must it not? A. Depends on what you mean by "wet."

Q. Take your definition of wetting. I am sure it is better than mine would be. A. If you take my definition of wetting, yes.

Q. Maybe you better state to the judge, if he doesn't understand already, what your definition of wetting a surface is. A. Wetting of a surface constitutes a process in which when a liquid comes in contact with a surface there is a change in energy at the interface.

Q. Now, then, if you applied an oil bath or oil film on this metal piece before you dipped it in the acid, do you know whether or not that would have any effect on the wetting of the metal by the acid? A. It's a guess. I would guess it would.

Q. Well, I think it would be a pretty safe assumption, without asking you to give any quantitative values, to assume that the rate of corrosion of a steel pipe by acid flowed down through the pipe would be different in the case of the acid being preceded by a flow of oil than if the inside of the pipe was clean or sand blasted? A. How different I wouldn't know.

Q. But it would be different. A. I would expect it would be some different. How different, I wouldn't know.

Q. And you didn't make any tests along that line?

Mr. Conner didn't suggest you make any tests with these pieces of metal after they had been oiled? A. No such tests were suggested.

Q. Did he tell you that in the defendant's acidizing process that the acid is preceded down the pipe by a column of oil? A. Well, at the time we started our tests, I don't think he did because our instruction was specific and did not include a discussion of the defendant's process.

Q. Has he since mentioned the fact to you and asked you to conduct any experiments on the basis of oil specimens? A. No.

Q. But has he mentioned to you that that is one factor that will influence the rate of corrosion down a well pipe? A. The answer to the question would be no, he has not told me that. On the other hand, I may have been told that the oil is in contact with—has been in contact with the pipe, but no one has told me the thing indicated by the question.

Q. Dr. Bartell, referring to the instructions that you received from the plaintiff's representatives as to the work or tests they wanted you to make for the purposes of this case, did they ask you to analyze these samples for lead, copper and iron, or was that your own idea? A. As I recall, that was our own idea.

Q. They didn't tell you that those were examinations or tests that they wanted made? A. As I recall not.

Q. What led you to analyze the samples only for lead, copper and iron? A. Well, an examination of the samples would readily show the presence of considerable lead, so it is perfectly obvious as to why we would test for lead.

Q. You could tell by just looking at the sample? A. No, but the simplest of qualitative analysis would show upon that.

Q. What about copper? A. Copper is not so readily detected. After going that far and finding that lead was present, and knowing that something else was probably present, because of the inhibition effects that we were getting, we naturally tested for other metals.

Q. As I understand it, this inhibition or reduction in

corrosion that you referred to could not be accomplished by the lead itself, because lead has a very limited action, and the results are due to the presence of copper in conjunction with the lead? A. As I recall, we made a test with lead salts alone to see whether that much lead would cause the inhibition that we obtained, and it did not cause as much as we obtained, so we suspected that something else must be there.

Q. Did you examine the storage samples to see if they contained any other agents or chemicals other than hydrochloric acid, water, and lead, iron and copper? A. We made qualitative tests for other things.

Q. You found some other things, did you not? A. Not in appreciable amounts, no.

Q. Well, didn't you find some arsenic in the storage,—in the raw acid? A. Not with the tests we made, the regular qualitative tests.

Q. You didn't examine sufficiently to determine whether there were any other chemicals in the raw commercial acid which could function as inhibitors? A. We didn't make an exhaustive analysis, no.

Q. I did not ask you about exhaustive. Did you make any analysis? A. I just mentioned that we did make some qualitative analyses.

Q. Have you got a complete analysis of those samples from the defendant's storage tanks, as far as you made a qualitative analysis, have you got a complete report? A. No, I have not, beyond the three metals.

Q. What else did you find in the raw acid qualitatively? A. I don't remember that we found anything.

Q. Would your notes show it? A. Well, after having found lead and copper and after having found the inhibiting effects we did I am not sure we looked beyond that, except we did make some qualitative tests for arsenic.

Q. Was that the only thing you made the test for? A. Just about, I think.

Q. These abouts and maybes are difficult for me to use your testimony on. I asked you, did you make any

qualitative tests for anything else? A. I will have to consult with Mr. Cardwell.

Q. That is perfectly all right. He is in on this at all stages.

The Court: I suggest one of you help the other in any way you want.

A. Mr. Cardwell informs me we did what I thought we did, we took the regular qualitative analyses scheme for detecting the inorganic constituents and did not find appreciable quantities of anything else.

Q. Well, have you got your qualitative report here so that we can see what you did find in the raw acid? A. I am quite certain we haven't. I don't know we even kept a record of it. Perhaps Mr. Cardwell would be willing to answer that question.

Mr. Cardwell: We have a record of it, but it is not here in the courtroom today.

Q. Is it in town, do you know?

Mr. Cardwell: Yes, sir.

Mr. Lyon: I would like to have it sent down to me, if you would.

Q. Did you examine these—well, as I understand it, you did not make any quantitative tests? A. We did not.

Q. About anything, for anything except lead, copper and iron? A. That is right.

Q. And you say you did not find in the raw acid or in the defendant's well acid at the tank, at the well, any other inhibitor except copper, lead and iron? A. We did not find them, no.

Q. Did you analyze the samples for oil, particularly the tank samples at the well, to see if they contained oil? A. Well, if there were oil present on the sample one would expect the oil to be on top of the sample, and no analysis was made of the solutions received for oil content.

Q. I believe you stated that in the case of the Crawford sample the oil was readily observable on top of the sample? A. Yes, there was considerable oil on top of the Crawford sample.

Mr. Owen: I beg pardon. That is the Stella Wilcox. A. That is right.

Q. (By Mr. Lyon) Excuse me. A. I am sorry.

Q. Now, what other samples from the defendant's tanks at the well did you look to see if there was any oil observable on the surface of the sample? A. We observed to note whether there was oil on the sample.

Q. Was there some in each case? A. There may have been traces on some of them.

Q. Did you examine—did you make a qualitative determination to test for the presence of oil in connection with those samples? A. I don't believe we did, with those samples, because, as I recall, they at most would be but traces of oil on the samples.

Q. Did Mr. Conner explain to you that in these operations from which these samples were obtained from the defendant's tanks at the direction of the Dow Company that the oil was circulated in the system so that the acid would be, when circulated, would pass through passages that had had oil in them, and be subject to contamination by oil?

Mr. Conner: If you please, Mr. Lyon, I think that is a misstatement. Such a fact as you are talking about only happened at one well. I suggest you refer to the record of the testimony taken at Midland.

Mr. Lyon: I am cross-examining the witness to see what they told him.

Mr. Conner: Perfectly all right, but the question is incorrect as to the facts you are assuming.

Mr. Lyon: I am asking the witness. A. May I have the question, please?

(The pending question was read by the reporter.)

Mr. Wiles: If that is not the fact it is an entirely improper question. Counsel can't ask a question of that sort unless the facts are truly expressed. He can't use that kind of entrapment.

Mr. Lyon: That is my understanding of the fact. It doesn't make any difference. I don't think counsel has the

right to get up and prompt the witness in answering the question.

Mr. Conner: We weren't prompting the witness here, Your Honor.

The Court: As I understand the question, it might be, and I don't know whether it is,—I wouldn't think he ought to ask a question unless it has already been proven or you have reason to think you will prove it.

Mr. Lyon: That is right.

The Court: You may not be able to. You might find something happens. But if you thought you were going to prove that, or if you claim it has been proven—

Mr. Lyon (Interposing): I understand that they admit it was true in one of these wells, and it was my information it is true in all of them. Maybe to a less degree.

The Court: Well—

Mr. Conner (interposing): Well, now, I would like to get it straight. The testimony is already in as to how these samples were taken. The opposite side was there and cross-examined. I think to Mr. Babcock's satisfaction it was determined when and where and how these samples were taken. They all came out of the manhole of the defendant's oil truck, and it is true in one case, which was the Crawford well, treated September 10, 1938, even though the acid came out of the manhole at the top part of the oil tank, it came out at a time after they had circulated the acid back from the tank through a valve and back into the tank again, which was their normal practice in this instance because they were mixing the acid with a substance called Klersol, which is not here in suit.

The Court: Would you have objection to it—because I am not sure I understand—if it was limited to that one sample?

Mr. Conner: If it is limited to the facts and correctly quotes the facts.

The Court: I mean—

Mr. Conner (interposing): Yes.

The Court: Not the rest.

Mr. Conner: If he limits it to that one case.

The Court: It would seem to me it is all right. All he is asking him to do is to tell him that, and it would not be surprising to me if he didn't. I don't know anything about that.

Mr. Conner: I am probably just an old fuss-budget, but what I hate in this case is a loose use of the record.

The Court: Has that been proven in one case?

Mr. Conner: Yes.

The Court: I don't see it would be anything bad to ask if the witness was told that. I am not saying you can think of everything in the world that was told him; I don't see any objection to finding out whether he was told or not. I will let him answer that. We have had this discussion.

Mr. Lyon: I would like to ask this be pointed out in the record. The reason I didn't limit my question to the one well was because their witness Shelley, whose deposition is in the record, gave this testimony, page 94 of his deposition—

"Q. Did you look into the tank? A. I think so, yes.

"Q. But you don't remember whether there was any oil on the surface of the acid or on the walls of the tank? A. Well, I just can't be absolutely sure about it. I just didn't have that in mind at the time. There probably was skim oil on it. You can hardly find a tank there isn't skim oil on it."

The Court: I will let him answer the question.

Mr. Lyon: Did Mr. Conner tell you anything about that subject at all or any of the other representatives of the Dow Company? A. As I remember at the time the samples were given to me no one mentioned the fact.

Q. Did they later? A. I learned later and I don't remember at the moment how, that that particular sample had received a treatment or processing which was different than that reported for the other samples. I did know that that sample was different but not at the time I got the samples.

Q. Well, you knew that the difference was in the fact

that there was a substantial amount of oil in the sample? A. I noticed that, yes.

Q. And are you prepared to state that there was no oil at all in other samples? A. No, I am not prepared to state that there was no oil.

Q. Did you make any test to determine whether or not, and if so in what quantity, the presence of oil would have any inhibiting effect on the acid? A. I don't recall that we have such data. We may have made some preliminary tests but I am not certain. We have not carried through any series of tests.

Mr. Lyon: Would it be all right to ask Dr. Cardwell if he knows there were any tests of that kind made?

Dr. Cardwell: I believe we did make some preliminary tests with oil.

Mr. Lyon: Well, I would like to know about those tests, what tests you made and what they showed. A. Well, we did not carry through on any of those tests because we were sufficiently occupied with the tests that we had under way.

Q. I would like to know what tests you did make on that subject and what the results were. As I understand from Dr. Cardwell there were some tests. Can you tell us what they were or refer to your records and tell us what they were? A. If I may see if I have anything in the record on that. (Witness conferred with Dr. Cardwell.) Some preliminary experiments were made using some of the oil that came on the sample that we have just referred to. Only a few preliminary tests were made.

May I have all of the question that was asked?

(Whereupon the question was read to the witness.)

A. Well, the results were of about this order. We did get an evidence of inhibition and the figures would be somewhere around 20 to 30% as the result of the use of that oil in the solution with the metal strips carried out just as we have described for the other experiments.

Q. Have you got your record or table on those tests here, either you or Dr. Cardwell? Can you produce the

data on those tests? A. I am sure they are not here. They were just preliminary experiments.

Q. Can you also send those to me along with this other item that I asked for? A. I will be glad to.

Q. I notice in these exhibits that you have produced here, these various tables refer to Series D, Series A, Series C, and so forth. I do not think that has been explained. I would like to have you tell us how many series there were in your tests which have these different letters from A to what? And tell us in each case what the particular series consists of? A. As referring to the metal? Q. Yes, I guess they refer to metal. On table VII, I see metal strips of strap iron, Series D; and in others you refer to Series C and Series A? A. Yes.

Q. I want to know how those series work out. A. The series would indicate batches of strap iron that were made up. If, for example, a certain number of pieces were to be cut from a given lot of strap iron, that batch would be referred to, for example, as Series A; and if some other batch of strap iron were used, that batch would be referred to as Series B; and another batch of strap iron would be referred to as Series C and so on.

Q. How many letters did you have in that series? A. The tables will indicate that. They will indicate that, just about. I note that we have a series as low as L, and it is presumable that we had approximately that many batches of strap iron.

Q. Each one of these series are for a batch of strap iron, or do those include this National Supply pipe, and all of this— A. Those numbers refer to strap iron only.

Q. Well, now, you made tests with each one of those different series A to L? A. Yes, sir.

Q. Well, now, first I would like to have you tell me, identify, if you can, as to what series A was, what Series B was, and what tests were made with each series? A. Well, that would be shown in the tables.

Q. Which tables? A. Well, in table I, for example, two series of irons were used. Series D for the first—for the

sample 8 Stella Wilcox, and sample 12-B from the Zahn well, with corresponding things.

Q. I understand that, but I want to know what different tests you made with series A. Haven't you got a schedule which would show? A. I would have no such schedule. It would be readily available.

Q. Could you make me up a schedule which shows each one of these series and shows each one of the tests made with those series? Can you do that and compare the data which you brought in, and filling the spaces would seem incomplete, because I will want to check into that? I don't see any reports here on Series K or Series E or Series F, and I want to know, because you evidently had a complete program here, and we only have tables covering part of the data, and I want to find out what the rest of the data is? A. Well, the rest of the data, it might be that some of the sets might have been small sets used for preliminary experiments.

Q. Well, I want to find out. A. Yes.

Q. You understand? A. We will be glad to try to get you the information, if we have the record covering it.

Q. All right. A. I am not sure we have the record covering series A to L complete, but I will see.

Q. Will you give me as complete a record as you can? A. Yes.

Mr. Lyon: Now, I have agreed with Mr. Owen to make this statement, Your Honor. Prior to last Saturday I asked him to furnish me certain material, particularly over the adjournment, and he has furnished me certain material, and I would want to state on the record what he has furnished me, so the record will show whether it was a compliance.

He sent me a table of the experimental data which was obtained in the acid corrosion tests as presented in and described in Table XIX, PX-167.

He also sent me a table of the experimental data which was obtained in the acid corrosion test with samples numbered 1 and 2 on the Stella Wilcox well.

He also sent me a table of the data obtained in the acid

corrosion test with the arsenic solutions prepared according to the disclosures on page 2, lines 74 to 78 of the Grebe and Sanford patent in suit.

And he also sent me a statement of the approximate dates on which the acid solution tests were made. I believe that is all you did send, Doctor. A. As I recall, and as I recall that was all that was requested.

Q. (By Mr. Lyon): I don't have in mind anything that you omitted? A. Yes.

Mr. Owen: Your Honor requested that a table be made showing the dates of purchase of commercial hydrochloric acid by the defendant and placed in its storage tanks at Mt. Pleasant, and of the different well treatments and taking of samples, and so forth, and I have prepared a chronological schedule here which will give you that information. I have given a copy of it to defendant's counsel.

The Court: That is what I want. Do you want to have that marked as an exhibit? It might be useful for somebody else. I am not asking it be done.

Mr. Owen: I think it might be marked as PX-172.

(The document above described was thereupon marked PX-172.)

REDIRECT EXAMINATION

Mr. Owen: Doctor, a considerable amount of cross examination referred to the percentages called for by the patent and included in those questions was one relating to what would be a relatively small amount of a corrosion inhibitor. In that connection I call your attention to a statement on page 1 of the patent, beginning in line 84, as follows: "The amount of arsenic compound added may be varied, but we have found that from 1 to 5 per cent thereof, based upon the weight of the solution will be satisfactory for the purpose." In view of that statement I will ask you what you understand the term relatively small amount to mean, that is, relative to what? A. Relative to the weight of the solution, strictly speaking.

Q. I will ask you if the amounts of lead, copper and iron you found in the defendant's solutions were relatively small amounts with respect to the weight of the solutions? A. They were.

Q. Now, how about the amounts of acridine, aniline, pyridine and quinoline, which you stated you had tested, being in some instances 1 per cent, and in other instances 3 per cent, and in other instances 5 per cent; do those refer to the percentages of the weights of the total solutions? A. That is right.

Q. In connection with your testimony regarding the testing of a 15 per cent hydrochloric acid solution containing 1 per cent of aniline—which you stated gave a 34 per cent reduction in corrosiveness—that is correct, is it not? A. That figure is correct.

Q. Now, will you tell the court how much more corrosive that solution containing 1 per cent of aniline was than the defendant's solutions which you have stated were 47 per cent inhibited; that is, how many times more corrosive. I will ask you, was the solution containing 1 per cent of aniline, than the defendant's solution, which gave 47 per cent reduction in corrosiveness? A. Why, in the ratio of 66 to 53; that is to say, the solution containing the 1 per cent solution of aniline had a corrosiveness of 66, in relation to the defendant's acid, which would have a corrosive value of 53, so that would be the ratio of the corrosiveness.

Q. How many or how much is that in times, one and a half, one and three-quarters, one and a quarter, or what?

The Court: Which one to the other?

Q. I want to know how many times more corrosive the aniline solution was than the defendant's solution. A. A little less than one and a quarter.

Q. Now, would you consider that solution which you made containing one per cent of aniline to be within the disclosure of the Grebe-Sanford patent? A. I believe it is.

Q. How many times as corrosive was that one per cent aniline solution as was the solution which was made up in accordance with the patent example, and which you stated was 97 per cent inhibited? A. If my figures are right, in

the neighborhood of the ratio of 66 to 3, or the corrosiveness of the one per cent aniline solution was about 22 times that of the arsenic solution referred to in the patent.

Q. Well, referring now to the solution you made up using acridine, and which I believe you stated reduced the corrosiveness of the acid 41 per cent, what would be the relative corrosiveness of that solution as compared with the defendant's solutions, taking them to be 47 per cent inhibited? A. The corrosiveness would be the ratio of 59 to 53. In other words, the corrosiveness of the acridine solution would be a little greater than that of the other solution referred to.

Q. Now, you stated, I believe, that that acridine solution was a saturated solution? A. That is right.

Q. By that, I understand that it took up all the acridine that the acid would dissolve? A. Yes; that is right.

Q. So that using that particular inhibitor, am I correct in stating that you could not get more than 41 per cent inhibition, according to your test? A. With our tests as conducted, at the temperature, constant temperature and all, one wouldn't expect to get much more reduction in corrosiveness with more acridine. It would not be in true solution, unless the suspended acridine might deposit on the plate, why, that would be the limiting value.

Mr. Lyon: I don't think the record shows what per cent of acridine went into solution in that test. May I ask? A. I recall we tried to make a one per cent solution, and it didn't quite all dissolve, so the answer would be the solution was somewhat less than one per cent.

Q. Mr. Owen: And I believe you have testified that the specific patent example using arsenic as the inhibitor contained only four-tenths of one per cent arsenic? A. Yes; this is right.

Q. Now, referring to your test using 1% of pyridine, your figure in that connection was 47% reduction in corrosiveness, as I recall. A. That is right.

Q. That is the same in that respect as the figure which

we have been taking for the reduction in corrosiveness of the defendant's sample, is it not? A. Yes, it happens to be of the same value.

Mr. Owen: I will state in this connection, Your Honor, I am adopting the 47% counsel for defendant used, not with the intention of being limited to that, because some of the tests show a much higher reduction.

Q. Then your solution containing 1% of pyridine would bear the same relation in rate of corrosiveness to the patent example using arsenic as the defendant's acids bear to the patent example? A. That is right.

Q. Now, taking up your test in which you used 3% of aniline and secured a 60% reduction in corrosiveness, how much more corrosive is the defendant's acid based on the 47% figure than the solution containing the 3% of aniline? A. The ratio would be as 53 is to 40 or the defendant's acid would be about 1.3% more corrosive.

Q. You stated that the defendant's acid at 47% reduction in corrosiveness would be about 1.3% more corrosive than the 3% solution of aniline, is that correct? A. That is right. The ratio would be as 53 is to 40, or about 1.3.

Q. Stating it another way, the 3% aniline solution would be about three-fourths as corrosive as the defendant's acid, or .7? A. Approximately so, yes.

Q. And how much more corrosive was that 3% aniline solution than the solution you made up in accordance with the patent example using arsenic? A. The arsenic gave a corrosiveness which could be expressed as 3% against this 3% solution of aniline, having a corrosiveness of 40%, so the ratio of the corrosiveness effect would be as 3 is to 40.

Q. Or the aniline solution would be about 13 times as corrosive as the arsenic solution, is that correct? A. That is right.

Q. Then your 5 per cent pyridine solution gave 65 per cent reduction in corrosiveness, and your 5 per cent aniline solution 67 per cent reduction in corrosiveness? A. That is right.

Q. Without asking you to make those computations I will simply ask if those two solutions were not still less corrosive than the defendant's solutions, that is, less in comparison with the ones I have previously referred to—well, that is a pretty complicated question.

The Court: It is 33. It is less than 40 and less than 66.

Mr. Owen: Yes.

Q. Then I will pass on down to the quinoline solutions. You made up three quinoline solutions, one containing 1 per cent of quinoline, one 3 per cent and one 5 per cent? A. That is right.

Q. And according to my figures each one of those gave 84 per cent reduction in corrosiveness? A. That is right.

Q. Now, how many times more corrosive were the defendant's acids than these quinoline solutions? A. About 3.3 times as corrosive.

Q. And how much more corrosive were the quinoline solutions than were the patent example solutions using arsenic? A. Approximately five times.

Q. So that here you have these quinoline examples five times as corrosive as the arsenic example of the patent, and still considerably less corrosive than the defendant's samples? A. That is true, assuming the defendant's sample has a reduction in corrosiveness of 47 per cent.

Mr. Owen: Now, the only other exhibits I want to offer are two sets of tables that Dr. Bartell furnished to Mr. Lyon, at his request, and I would like to offer this set in connection with the copy of Dr. Bartell's letter to Mr. Lyon dated August 4th, which states:

"Acting upon your request I am sending you herewith the experimental data which was obtained in our acid corrosion tests with samples numbered 1 and 2 from the Stella Wilcox well." I will offer that carbon copy of the letter and the four sheets of data as PX-247.

(Whereupon the document above referred was marked PX-247 by the reporter.)

Mr. Owen: I offer as PX-248 carbon copy of the letter written by Dr. Bartell to Mr. Lyon August 4th, reading as follows:

"Acting upon your request I am sending you herewith the experimental data which was obtained in our acid corrosion tests as presented in and described in our Table XIX (PX-167)," and attached to that copy are three sheets of data.

(Whereupon the document above referred to was marked PX-248 by the Reporter.)

Mr. Owen: Doctor, have you recently made corrosion tests on a number of commercial acids? A. Yes, we have.

Q. Where did you obtain the acids? A. The acids were obtained from the Dow Chemical Company.

Mr. Owen: I will state for the record, Mr. Lyon, that these samples were either telegraphed for, or written for, by Mr. Crawford. Mr. Crawford either personally, or someone under his direction, wrote or wired to these various chemical companies, asking them to send one and two gallon samples of their commercial hydrochloric acid, and as those samples came into the Dow Chemical Company, they were sent down to Dr. Bartell, without being opened. That is the way they came to you, is that right, doctor? A. Yes.

Q. And you opened them and made tests of them? A. Yes.

Q. Now, will you state what samples you received and tested, and the results of the tests.

Mr. Lyon: Hasn't he got that all in a table here? Isn't that all tabulated here? Can't you offer this paper without him reading it?

Q. Mr. Owen: Have you a table showing the names of the companies from whom these samples were received, and the results of your tests? A. Yes, I have.

The table was offered and received as PX-358.

Q. Well, now, state, doctor, how you made these tests, that is what technique you followed? A. These tests were made in exactly the same manner that we had previously adopted as standard tests for making our acid corrosion tests. The metal used was strap iron cut to the size of one inch by one-eighth by three-sixteenths. The solutions were

not agitated. The experiments were carried out at 85 degrees Fahrenheit. The volume of the acid solution on test was 50 c.c., the same as before, and the time of the test was 16 hours. It will be noted that two series of strap iron were used. That was because in preparing strap iron for tests a limited number of pieces are available from any one series of strap iron and we made use of two series.

CROSS EXAMINATION

By Mr. Lyon: Q. Doctor, referring to these tests that you have listed on PX-358 produced today, these various tests on the corrosiveness of these samples of commercial hydrochloric acid, when were these made? A. The acids were obtained on the 26th of August and the tests have been made since that time. Within the last two weeks.

Q. And did you make an analysis of these various commercial hydrochloric acids referred to on this exhibit 358 to determine their copper, iron and lead content? A. No, we did not.

Q. Or either of those three metals? A. No.

CLERK'S COPY.

DR. CARL F. PRUTTON,

a witness called on behalf of Plaintiff, testified as follows:

DIRECT EXAMINATION

My name is Carl F. Prutton. My residence is 2217 South Overlook Road, Cleveland Heights, Ohio. My occupation is professor in charge of the chemistry and chemical engineering department, at Case School of Applied Science, in Cleveland, Ohio.

As to my education, I received the Bachelor of Science degree, the Master of Science degree, and Doctor of Philosophy. My experience in chemical matters has been connected with both my educational training and industrial experience as a consultant for many concerns. I have been connected with Case for twenty-one years. Electrochemistry is one of the subjects that I have taught for many years.

By Mr. Owen:

Q. Have you conducted any experiments with a view to ascertaining what effect the presence of small amounts of copper, lead and iron in hydrochloric acid solutions has on the corrosive effect of the acid on iron or steel? A. I conducted two sets of tests, to determine the effect of copper, lead and iron in hydrochloric acid solutions, upon oil well tubing. The first set of tests was conducted upon a small laboratory scale; the second series of tests was conducted on a large piping set up, in which large volumes of prepared acids were run through the system. The tests were conducted in the laboratories of the Case School of Applied Science during the last two years, or two and a half years.

The small scale tests were performed in the following manner: One inch sections of 1¼ inch type C oil well tubing were cleaned under an exact procedure of cleaning, following the following steps: First, the small sections of

tubing were washed thoroughly with a fifty-fifty mixture of benzene and acetone. Second, immersed in 15 per cent c.c. hydrochloric acid for one hour. Third, rinsed thoroughly in water. Fourth, dried in an oven at 105 degrees Centigrade for one or two minutes, simply to remove the moisture.

The ends of the samples were then carefully faced off in a lathe. The handling of the sample in that operation was done avoiding any contact of extraneous material, handling with metallic tongs, and there was no oil used in the cutting operation. In this manner an exact length of oil well tubing could be obtained.

The sixth step was to brush the inside surface of the tubing with a hardened steel wire brush, known as a flue cleaning brush, which removed any loose particles of metal from the inner surface of the sample. The outside of the sample was burnished on a clean wire burnishing wheel, to remove any loose particles. The seventh step was, the sample was then rinsed in acetone, and then dried in an oven at 105 degrees Centigrade for about one minute, and then cooled in a dessicator, and weighed.

The test procedure was to take these small sections of oil well tubing which had been cleaned in the manner that I just described, and suspended them after, of course determining their initial weight, suspended them in a two liter bottle by means of a glass hook coming through the top of the bottle in the middle of the sample of acid on which the corrosiveness was to be determined. 1360 c.c. of acid were placed in the bottle. The bottle was immersed in a constant temperature bath at 30° C. and when the acid in the bottle had reached the 30° C. temperature the steel sample was then inserted and the test was started. The sample was removed at the end of the three-hour period, was washed with water, then with acetone, and then quickly dried and final weight of the sample determined. The loss in weight from the specimen was then calculated by subtracting the two weights—the difference between the initial and the final weights.

The results of these tests were reported in two figures. First, the grams of steel dissolved per square meter of area of the sample per hour of acid contact; and secondly in terms of the percentage reduction in corrosiveness when a given sample of acid was compared with chemically pure acid, exactly in the same manner calculation that Dr. Bartell used in expressing his results.

Q. What acids did you use in these small scale tests? A. The acids that were used in the small scale tests, first, a determination was made upon chemically pure acid which was diluted to 15% concentration and, of course, the results of that test expressed on the basis of percentage reduced corrosiveness would be zero because it was the blank run. Samples were then prepared from 15% chemically pure acid, which contained various amounts of copper chloride, of lead chloride, and of iron chloride. The chemically pure salts were dissolved in the acid in definite proportions to give a range of compositions that covered the range of compositions reported to us as having been found by Dr. Bartell in his analyses of the defendant's samples obtained in the acidizing of oil wells.

The second test following the blank, the acid contained 15% hydrochloric acid, 473 parts per million of iron in the form of iron chloride, 242 parts per million of lead, and 2.14 parts per million of copper. The percentage reduction in corrosiveness of that acid as compared with the C. P. was 59.7.

The third sample, 15% hydrochloric acid contained 473 parts per million of iron, 242 parts per million of lead, and 3.72 parts per million of copper. The percentage reduction in corrosiveness of that acid as compared with the C. P. was 70.

The fourth sample contained 15% hydrochloric acid, again 473 parts per million of iron, 510 parts per million of lead, and 1.86 parts per million of copper. Percentage of reduction in corrosiveness as compared with the C. P. acid was 62.8.

The fifth sample contained 15% hydrochloric acid, by

weight 473 parts per million of iron, 510 parts per million of lead, and 4.18 parts per million of copper. The reduction in percentage of corrosiveness was 71.4.

The sixth sample containing 1430 parts per million of iron, 204 parts per million of lead, and 1.86 parts per million of copper, the percentage reduction in corrosiveness was 61.1.

The seventh sample, 15 per cent HCl, 1440 parts per million of iron, 530 parts per million of lead, and 3.44 parts per million of copper, 70.5 per cent reduction in corrosiveness.

The samples were all run in duplicate and the individual determinations did not vary over one per cent from each other, and the average is reported.

The conclusions from these tests are that copper chloride and lead chloride and iron chloride in the compositions such as reported to me as having been found by Dr. Bartell in the defendant's acids, reduce greatly the corrosive effect of the acid upon oil well tubing, and the reduction is around 70 per cent in this laboratory test. We have made some other tests in which the proportions have been varied somewhat from these figures, but the percentage of inhibition does not change greatly from these.

Q. Well, then, will you compare the results of the different tests you have made, six in number, as compared with the C. P. hydrochloric acid blank, and explain how the effect of varying the amounts or the proportions of iron, lead and copper have affected the corrosiveness of the solution? A. Well, these results would indicate quite definitely that iron has practically a negligible effect in the concentrations that were used here, and if you will look at Test 2, in which 473 parts per million of iron were used and about 240 of lead and a little over 2 of copper, it was 59.7% reduced in corrosiveness. And when the iron was stepped up in Test 6, to 1430 parts per million and the lead was about the same, 204 instead of 242, and the copper was around 2 parts per million, the percentage corrosiveness reduced was 61.1, or substantially the same. In other words, the iron,

variation in iron concentration over this range of about 470 parts per million to over 1400, the iron has practically no effect upon the amount of inhibition that is obtained.

With the copper, why, you can see a definite increase in going from Test 2, where 473 parts per million of iron were present and 242 of lead, but only 2.14 of copper gave 59.7 per cent reduction in corrosiveness. In Test 3, when the iron and lead contents were identical and the copper content stepped up to 3.72, or not quite double that in Test 2, the percentage of inhibition went up, or the percentage reduction in corrosiveness went up to 70 per cent. In other words, doubling the copper content from 2 parts per million, approximately, to 4 parts per million, increased the inhibition about 10 per cent.

The lead concentration, if you try to analyze it, it shows some slight increase in inhibitive power, but not nearly as great as the copper, so the iron has practically no effect, the lead has some effect and copper has a very appreciable effect, which agrees with Dr. Bartell's tests.

Mr. Owen: I supposed I had a table showing what the Doctor has been testifying to, and which I intended to offer, but it is apparently not available today. I would like to offer it tomorrow morning.

The Court: You may do that. I want to have it as an exhibit. I will give you a number now. It will be PX-173.

(Plaintiff's Exhibit No. 173 was reserved.)

Mr. Owen: You referred to another series of tests which you conducted, more or less approximating conditions which are present in acidizing an oil well. Will you describe those tests and the apparatus and materials you used in making them? A. In the large scale tests we used this pipe "C" oil well tubing, which we purchased from the Oil Well Supply Company of Pittsburgh, Pennsylvania. There are a number of charts and figures. I don't know which ones you want to introduce in evidence.

Mr. Owen: Let us use PX-174 for the drawing showing the apparatus which you used in your tests, and which you are now going to describe.

The Court: PX-174 will show this larger experiment, is that it? I am thinking of it as the bigger one.

Mr. Owen: Yes. Now, will you describe the apparatus and the materials, and the manner in which you conducted those large scale tests? A. The apparatus employed was, first, as shown in Figure 2 (PX-174) in this report that I have. In these large scale tests, approximately 200 gallons of 15 per cent hydrochloric acid were run through 112 feet of this 1½ inch oil well tubing—15 per cent commercial hydrochloric acid, and 15 per cent commercial hydrochloric acid to which various metal concentrations were added. The acid was all purchased from the Grasselli Division of the du Pont Company, in Cleveland, and it was regular commercial hydrochloric acid, or muriatic acid, delivered in carboys, and we transferred the acid from the carboys through glass siphon tubes into a stoneware storage crock, and diluted the acid with Cleveland city tap water to the correct concentration of 15 per cent.

Q. The stoneware crock is the one shown in the photograph, PX-175? A. Yes. The stoneware crock used was a brand new stoneware crock, obtained from the Myers-Knight Company, of Akron, and was thoroughly soaked in hydrochloric acid for several days before using it in tests, and between tests was soaked in 15 per cent hydrochloric acid to be sure that there was no contamination from one test to another.

The acid was prepared in that crock, and drained from the bottom of the crock through the spigot into the piping system, and connections were made between the piping system and the stoneware crock by means of pure gum rubber tubing, short lengths, and short lengths of 1 inch Pyrex tubing.

The Court: Is that the part that is the top of the tubing? A. Yes, the top of the tubing. Part Y is the start of the steel tubing. The line connecting to the crock from point Y back to the crock and the line extending up to the top of the crock is all Pyrex tubing, connected with short lengths of rubber tubing whereever connections had to

be made. All of the rubber connections that were used in this work were soaked in hydrochloric acid for several days to make certain no soluble constituents of the rubber tubing would dissolve into the acid on the actual test.

The entire line of tubing was made up of 20-foot sections of this oil well tubing connected together with couplings of the same tubing. The couplings were supplied with the tubing when we purchased it. And elbows were prepared by cutting the threaded ends off of several lengths of the tubing and welding those short sections together to make elbows with threads on them. That length of 1¼" oil well tubing, extending for a total distance of 112 feet, was slightly inclined so the acid would run through it. I think the fall from one end to the other was about six to eight feet in the 100 foot length.

The Court: That is not shown. A. No, this is just a schematic drawing. It was on a slight incline. At the lower end of the oil well tubing, the discharge end, a rubber stopper was inserted into the last length of oil well tubing and through that a short length of 1" diameter Pyrex tubing, and under that a short length of pure gum rubber tubing. Extending beyond that rubber tubing was another short length of Pyrex tubing that dipped into the top of an open bottle. On this rubber tubing we had a screw clamp so we could adjust the rate the acid ran out of that piping system. The bottle had an orifice in the bottom, this discharge bottle that the acid ran into of one-gallon capacity, and by keeping the height of the acid in the bottle at a definite level with this definite diameter orifice at the bottom, the rate of discharge was maintained constant at one gallon per minute, with a definite size hole in the bottom of the bottle, side of the bottle, and a definite liquid in that open bottle running into this tube you get a definite rate of flow. It is a standard method of measuring the flow. The rate of these tests was adjusted to one gallon of acid per minute.

The Court: Your final adjustment was by the size of the stream? A. By the size of the stream, by the height

of the liquid column. The higher that liquid would be in the bottle the greater the run out of the hole in the bottom. In other words, we had a constant size orifice.

The Court: The adjustment was by the size? A. By the size, by the screw clamp. The size of the stream was adjusted so that we maintained a definite calibrated level at the bottom. At the top of this system connecting to the Pyrex tubing leaving the crock was a gas vent which permitted the escape of any hydrogen gas from the system. It would simply bubble back up the tube and out of the Pyrex tubing vent at X. We discharged that back into the top of the crock because sometimes the bubbles of hydrogen carry small amounts of acid with it, a little slug of acid would be shot out.

The Court: How did you get it back? A. We just bent the tube over the edge, up over the edge. These tests were run at 85 degrees Fahrenheit. All of the tests were run after the acid was adjusted to 85 degrees Fahrenheit. The results of the tests and the data taken are given in individual tables that have been prepared, and if we take up the first test that was made—before I take up this first test I think it would be well to describe the method of cleaning out this tubing.

The Court: Right in this same book? A. It is described in there, all the methods that we used. It is the first stiff sheet of tabular data there, marked Table I.

The Court: I was wondering if you wanted the whole thing in. It seems like a very carefully worked out and prepared document. I was wondering if you wanted this as an exhibit. I am not trying to outline your course of procedure. I thought before we started using up letters I would ask you whether you wanted it all in. You have got minutes on this one.

Mr. Owen: I have got minutes on this. This is my copy and I have marked it up. Let us consider this tonight.

The Court: Suppose we call Table I Exhibit PX-176. And when we get one that you can spare and want to we

will put it in. I will save you the place. Table I is PX-176.

(Plaintiff's Exhibit No. 176 was reserved.)

The Witness: The method of cleaning the tubing was substantially the same as was used in cleaning these small specimens that I described in the laboratory test. The first cleaning operation was the washing of the tubing with a solvent, acetone benzene, to get grease and paint and oil off the outside and inside of the tubing, and then the tubing was pickled with hydrochloric acid inside, fifteen per cent, and then washed thoroughly and then reamed out or brushed out with this very stiff flue brush, which was kept very clean and we used a new one on about every second test to remove any very loose particles of metal that may have been on the inside of the pipe.

And the inside of the pipe, when that cleaning operation was over, had a burnished appearance. It was very bright looking, very clean. The outside of the pipe in these tests was not wire brushed as we did in the laboratory test, simple because the outside of the pipe was not exposed to the acid in the large scale tests, but in the small scale tests it was exposed. So we did not give it the same cleaning on the outside.

The tubes and fittings were all accurately weighed, and the accuracy of the weighings was to about two grams, and so we could determine the loss in weight of each fitting and each length of tubing in the test. And the pipes were then carefully assembled, after the cleaning operation and weighing.

The acid was run through the pipe system after it reached a temperature of 85 degrees Fahrenheit, and the rate was adjusted rapidly to one gallon per minute. That was easily done. It occupied a very short time. And then, as the acid ran through the tubing, we took periodical samples of the discharged acid leaving the tubing and saved those samples for analysis and future examination.

At the end of the test, the tubing was taken out and washed, cleaned and re-weighed, dried, of course, and re-weighed to get the loss in weight or a rough check on the

loss in weight, but the amount of iron that was picked up by the acid was determined very accurately by analysis of the inlet acid and analysis of the outlet acid during the run.

Now, if we go to Table I, the first run was made using 15 per cent hydrochloric acid, prepared from this Grasselli commercial acid, diluted with Cleveland tap water. Run 1-A, the first column gives the run numbers. The second column gives the general conditions of tests and of the acid used, 15 per cent hydrochloric acid directly from the stoneware crock through the tubing, temperature of 85 degrees Fahrenheit, at the rate of one gallon per minute, and the Series 1 tubing.

Now, in order to insure that we had made a valid test, we simply picked at random five lengths of this oil well tubing, numbered them carefully and called that Series 1 tubing, and every test in which Series 1 tubing is used has the number 1 in front of it. So 1-A was run with Series 1 tubing. We then picked five other lengths of oil well tubing at random and numbered each length and called those tubes Series 2 tubing, and so every test run upon Series 2 tubing has the number 2 in front of it and the letter following. It is a different tubing. So we ran the 15 per cent commercial acid, 1-A is running 15 per cent commercial acid through Series 1 tubing, and then we took this other set of tubing, completely different, and we ran commercial acid through it. So we have two separate, completely separate sets of tubing, and we kept those sets together in the subsequent runs.

The first run, 1-A, shows a run with the commercial acid diluted to 15 per cent concentration, temperature 85 degrees Fahrenheit, and in the third column in this table are the gallons of acid through the tubing between samples.

Now, we took a sample about every 20 minutes, of the effluent acid, and at that time, at the time of taking the sample of effluent, we determined the number of gallons of acid that had run through the system by noting the fall of level of acid in the crock. We could calculate the amount that had gone through. So at the time that 27½ gallons

of acid had run through the tubing, if you follow over you will see that the sample No. 1, in the samples taken at the outlet, is opposite that particular volume of acid that was discharged, and so every 20 minutes we took a sample of the discharged acid.

At the start of the test, each of these tests, the first gallon of acid that came through was distinctly dark. It had a darker color than the rest of the acid, and we found in each case the initial acid that came through, the first gallon, definitely contained a greater amount of iron than the rest of the acid taken at subsequent times. But that concentration of iron in that first gallon, although it was high, was not an appreciable part of the total iron dissolved. It was a very negligible part, and we have shown in these tables, just to make them complete, we have shown the concentration in that first gallon of acid.

The Court: Now, that acid you took where? A. We took it down at the bottom. It just ran out of the bottom through the whole piping system.

The Court: All through the pipes? A. Yes, and we took a sample out of the first gallon of acid coming through, which was a little darker than the rest. After that it cleared up and got a certain definite yellow color, due to the iron, and our iron analysis fell down to a fairly stable value, and we took a sample every twenty minutes of the discharged acid, and we took two samples, as shown in the fourth column under the general heading of samples taken at the inlet, the fourth major volumn, samples taken at the inlet.

The Court: That is way up at the top? A. At the crock. We took two samples, one at the start of the run and the other at about half way through the run. Those two samples were blended together to make a composite sample, composition of the acid leaving the crock, just to save analysis.

The Court: You didn't analyze that? A. We did not analyze each separately. We mixed the two together. We took an equal volume of each.

The Court: I took it from what you said this is in the

initial test? A. In the crock. They should be just alike. There was no necessity of checking each one. The composition of that inlet acid is shown in this sub-head, specimen Fe, under the fourth column of samples taken at the inlet, and the next column with the sample number.

The Court: 9.3 parts iron to a million parts of acid? A. Parts of acid.

The Court: Of the whole solution? A. That is correct. Now, under samples taken at the outlet, the first sub-column and sample number, the initial sample out, that was the first gallon of acid coming through, was slightly darker than the rest. Then a sample was taken at the end of twenty minutes and at twenty minute intervals thereafter. Those 20-minute samples were blended together to make composite samples.

The Court: Not the first one. A. The first one wasn't considered. We took one sample right at the start. The first gallon of acid through we took a sample. That is the initial out. No. 1 is the first sample taken at the end of the first twenty-minute interval. The initial out is the sample of the first gallon of acid that left the tubing.

The Court: Well, what is No. 1? A. No. 1 was taken at the end of twenty minutes, at the end of the run.

The Court: All right. Now I've got you. After that initial out you bunched three together. A. 1, 2, 3; then 4, 5, 6, and then 7, 8, 9 and 10 were bunched together in proportion to the volume that had run through the pipe at the time analysis was made for the iron content in those effluent samples or composite samples and the parts per million of iron is reported in the second sub-head under "Samples Taken." The initial sample out, 2240 parts per million of iron; the first composite sample of 1, 2 and 3, 1135 parts per million; the second composite sample 4, 5 and 6, 1450 parts per million; the third composite sample, 7, 8, 9 and 10, 1405 parts per million.

The Court: Now I am curious to know that there is a peculiar curve there. It is a way up and down, then up and then down. I am wondering if you had analyzed each one

of those samples whether you would get another little hump in there. A. The initial out is very easily explained. In the burnishing operation and cleaning there were little particles that dissolved rapidly so that shouldn't be considered. The subsequent, although there is some variation, the variation is not a great deal. I think particularly in the last two samples—1450 to 1405 is not a great deal, and the 1135 that, of course, is lower than the 1450.

The Court: What do you think No. 1 would be as compared to No. 3? A. Well, it might be 10% difference—something like that; maybe 100 parts per million.

The Court: One or three? A. I think No. 1 would be lower than No. 3, possibly.

The Court: In other words, you think that that first gallon out had gotten out all the loose stuff? A. All the loose material.

Mr. Owen: I might call your attention to the fact that in subsequent tables, II, IV and III, which were all run with commercial acids without any additions of metals, the same ratio or the same phenomenon appears in I, II and III. That is, the first initial out sample is high in iron and then the next three, the composite is lower than the second three, and the final four drops off a little from the second three of that sample that run through the series.

The Court: What you found was not free iron but ferrous what? A. Ferrous chloride.

Mr. Owen: Now, Doctor, explain the entry in the last column. A. The last column report is the number of grams of iron picked up by the acid in running through the tubing. The amount of iron at the inlet acid was calculated and the amount of iron at the exit was calculated and the difference shows an increase in iron content and it amounted to 1043 grams of iron or a little over two pounds of iron dissolved.

The Court: In other words, if you take this ferrous chloride and bring it up so you didn't get your free iron you would have two pounds? A. You would have two pounds of metallic iron. Ferrous chloride is $FeCl_2$. Now,

the second table, Table II in the first column, the run number is given as 1-AA, the "1" designating it as Series 1 tubing. The run 1-AA was a blank run of fifteen per cent commercial hydrochloric acid of the same type described in the first run, run on Series 1 tubing, and the conditions were exactly the same as in the first run. And in this case the initial crock acid contained four parts per million of iron, and the composite samples taken at the exit during the run, the initial out, was 3,540 parts per million. The first composite 1180, the second composite 1263, and the third composite 1218 parts per million of iron, making a total of 943 grams of iron dissolved in that particular test from the tubing.

Then in Table III we ran this diluted 15 per cent commercial acid through the second series of tubing, using entirely different tubing than Series 2 tubing, so in Table III we have run 2-A, "2" designating the series of tubing, and "A" designating a blank commercial fifteen per cent acid. The temperature, rate of flow and so forth was the same as in the other tests. The inlet iron concentration in the acid, the acid going in contained 9.3 parts per million of iron, and the samples of acid leaving the system, the initial out, 3,580 parts per million of iron, the first composite sample 1292 parts per million, the second composite sample 1357 parts per million of iron, and the third composite 967 parts per million. The total amount of iron dissolved from this tubing was 919 grams. Then on Table IV we have a duplicate blank run with a smaller amount of acid. This is run 2-C of Table IV. The 15 per cent acid was run through from the stoneware crock in the Series 2 tubing at 85 degrees Fahrenheit. The composite of the crock sample was 7 parts per million iron. The analysis of the two samples, the initial acid out, 1330 parts per million. The first composite sample, 1143 parts per million of iron. The second composite sample 1088 parts per million of iron. Third composite sample 1070 parts per million of iron. And the total amount of iron dissolved, 791 grams. So there are the results of four blank runs.

The Court: I don't consider it of any importance, because it is so small, but it does show that there was less than half as much iron in the crock in the sample in Table II. They got down to half. A. We had purchased several batches of acid, and it varied somewhat from the one shipment to another.

The Court: Each one of these acids are different purchases? A. No, not each one. I have a record of our purchases, and sometimes the purchases overlap the runs. We didn't run the same acid through two runs. We purchased several batches of acid from the Grasselli Company and if we had three or four carboys left over, we used those three or four and it possibly went into the next shipment.

The Court: It was so little I didn't consider it important. I didn't count it as being important. And yet I was curious if it was the same purchase at the same batch how it would have to vary even that much. Do you know whether those were the same purchases? A. I don't think I could tell. I could not tell.

Mr. Lyon: Can I ask if these different batches or different purchases of raw hydrochloric acid were checked against any C. P. blanks so that you could tell the difference? A. We have analyses and inhibition tests of every batch of crock acid that was used in every run that was made.

Mr. Lyon: Against C. P. acid? A. Against C. P. acid and analyses. They are not in the report.

The Court: But you have those figures? A. We have those figures, if they want them. They were substantially in every run within a few per cent of the corrosiveness of C. P. acid, the commercial acid that we obtained from Grasselli.

Mr. Owen: I would like to have the Tables II, III and IV marked as PX-177, 178 and 179 and offered under those numbers.

(Plaintiff's Exhibit Nos. 177, 178 and 179 were thereupon reserved.)

The Court: I don't believe anything has been offered.

I think I will say Exhibits 1 through 179, inclusive, have been admitted.

Mr. Owen: Before going on with the examination of the witness, if Your Honor please, I think it may be well tc identify these tables that we were going to offer; and I will state that a copy of this report was handed to defendant's counsel just before the adjournment last evening.

Now, PX-173 was a table to be supplied, and I find that on this report, pages 7, 8 and 9, are several tables which I had intended to combine as that exhibit, so I suggest that the table on page 7 be marked PX-173-A.

(The table in question was then marked PX-173-A.)

Mr. Owen: Then on page 8 there are two tables which I will have marked PX-173-B and PX-173-C; and on page 9 there is another small table which I will have marked PX-173-D.

(The tables above mentioned were then marked PX-173-B, 173-C and 173-D.)

Mr. Owen: Then, Your Honor, to identify the other exhibits in this report, the exhibits which were identified last evening, PX-174 is on page 34 of the report. That is the drawing of the apparatus.

On page 35 there is an enlarged detail of the delivery end of the apparatus, and I would like to have those both included in this exhibit, marking page 34 as PX-174-A and page 35 as PX-174-B.

(The pages above mentioned were then marked PX-174-A and 174-B.)

Mr. Owen: Then PX-175 is the photograph of the crock, which is on page 33.

(The photograph was then marked PX-175.)

Mr. Owen: PX-176 is Table I, which is on page 25.

(The table above mentioned was then marked PX-176.)

Mr. Owen: PX-177 is Table II, which is on page 26.

(The table above mentioned was then marked PX-177.)

Mr. Owen: PX-178 is the table on page 27.

(The table above mentioned was then marked PX-178.)

Mr. Owen: And PX-179 is the table on page 28.

(The table above mentioned was then marked PX-179.)

Mr. Owen: Doctor, at the adjournment last evening you had discussed your Tables Nos. I, II, III and IV. Can you state what the average loss of weight, or, in other words, the average amount of iron taken up in the acid as it passed through the pipe would be for these four runs, basing it on so many grams per hundred feet of tubing per hour of contact between the acid and the tubing? A. I have those figures here. In runs 1-A and 1-AA, taking first 1-A, the amount of iron dissolved from the tubing, expressed in grams of iron per hundred feet of length of tubing per hour of contact was 289 grams. In run 1-AA the rate of dissolving the iron per hundred feet of tubing per hour of contact was 273. So in the first set of tubing, that is, tubing in Set No. 1, why, the average was 281 grams.

And in the second series 2 tubing runs, with the commercial 15 per cent acid, run 2-A, the rate at which the iron dissolved per hundred feet length of tubing per hour of contact was 256 grams of iron. In run 2-C the rate of dissolving of the iron per hundred feet length of tubing per hour of contact was 239 grams. And the average on that tubing was 248.

Q. And have you the average for the four runs? A. You could. You could average 248 and 281. It would be 264½.

Q. Did you make runs similar to those covered by your tables Nos. I, II, III and IV, in which you made additions to the acid? A. Yes. Those results are reported in Tables V, VI, VII and VIII.

Mr. Owen: I might as well at this time mark those tables as exhibits. Table V as PX-180. Table VI will be 181; Table VII, 182, and Table VIII, 183.

(The tables V, VI, VII and VIII were thereupon marked respectively PX-180, 181, 182 and 183.)

Mr. Owen: Now will you explain in connection with your Table V what that one was, how it was conducted? A. The run 1-B which is reported, or the data reported on Table V, the commercial acid was diluted in the stoneware crock to 15 per cent concentration and metallic chlorides,

that is iron chloride, lead chloride, and copper chloride were added to correspond to the composition of defendant's acid as reported by Professor Bartell. Those amounts of metallic chloride were added to the acid. The acid was agitated and before running the acid through the tubing system, why, a chemical analysis was made upon the acid to determine the metallic concentrations, to check on the weights of chemicals that had been added.

Mr. Lyon: Did he add the total amounts that were found in the defendant's well samples or did he add the amounts that represented the difference between the defendant's well samples and the amounts that were in the raw commercial acids? A. We added the difference between the amounts found in the commercial acid and the figures as reported here. In other words, we added the amount of copper, lead and iron that would build the final concentration up to the figures we desired.

Mr. Owen: And what were the figures to which you built up the acid? A. The figures we built up the acid to correspond to the compositions that Dr. Bartell recorded as having been found in the defendant's samples.

Q. Well, for the purpose of the record, it is in the record, but to get it in connection with your testimony, please state to what copper and lead content you built up this acid before running it through the pipe. A. The contents are all reported on the sheets and therefore if I can go through those it would specifically give those concentrations and there will be no question about it.

Q. Well, now, as I understand, figures indicated on Table V at the bottom of the second column show the amount of lead and copper contained in the solution at the beginning of the run. A. That is correct.

Q. Now before we go into this, I will ask you if you analyzed these commercial acids as you received them or if you tested them for inhibition? Please state just what you did and what you found. A. The commercial acids were not analyzed as we received them. The commercial acids were analyzed after they had been diluted to 15% concen-

tration in the crock just prior to adding the chemicals to the acid. The reason for doing that, of course, was we used approximately 8 carboys of acid and we wanted to be sure that the acid that we finally had in the crock before we added the chemicals was representative of commercial hydrochloric acid diluted to 15%. Therefore, the analysis was performed at that time to insure no other impurities had gotten in in the transferring of the acid from the carboys to the crock and in the dilution of the acid. And so we analyzed the acid at the time after it had been diluted to 15% with tap water before these other chemicals were added.

Q. What amount of inhibitor, or what amount of inhibition did you find in the commercial acids as diluted to 15 per cent? A. The per cent inhibition as found in laboratory tests on this diluted 15 per cent acid ran from 0 per cent to a maximum of 6½ per cent inhibition, when compared in corrosiveness with 15 per cent C. P. hydrochloric acid.

Q. And those figures you have just given are for the solutions which you used as they existed before the runs were made, is that right? A. That is correct. Before any additions of metallic salts were made.

Q. Now, will you explain your Table V?

Mr. Lyon: Can I ask one question, Mr. Owen? The witness said that this figure at the bottom of column 2 corresponded to some figure that Dr. Bartell had given. I am unable to find in Dr. Bartell's reports where any of the samples of defendant's well acid that he analyzed, which he reports for these parts per million of lead and copper, so I am unable to understand what figure Dr. Bartell gave to the witness. A. I would like to correct the statement I made prior. Two of these runs, that is, of these runs with synthetic chemicals, were made to duplicate acid which we prepared in a Menaul tank which contained a lead sheet. We duplicated the Menaul tank system of the steel tank and lead sheet at the bottom which was being used to transport their acid, and we will report on those tests later, and

we got a certain composition of acid out of that tank, which differed somewhat from the field samples that were reported, so two of these tests are tests in which we ran the same composition of acid that we got out of that Menaul type tank, which did not differ greatly in the composition of the inhibiting metals from the field sample analyses as reported by Dr. Bartell, so two tests are run upon synthetic acid mixtures duplicating the Menaul type acid that we obtained out of the Menaul type tank, and two of them duplicate the analyses as reported to us by Dr. Bartell through Mr. Rebbeck of the Dow Company.

Mr. Owen: I think it is a matter of little importance whether these metal contents correspond exactly with Dr. Bartell's figures, or not. What these tables show is the effect of the presence of the amount of copper and lead which are specified in the tables, and whether they exactly agree with some other tests I do not think is important, so I will ask the court and the witness to consider these tables individually, and explain just how much copper and lead were in each of these runs—how much copper and lead were contained in each of these runs.

The Court: I am not to understand, as I understand it, that your Table V is exactly according to the formula of the defendant's acid, as analyzed by Dr. Prutton? A. It is not.

The Court: It is a synthetic one that you made? A. It duplicates an acid that we made in a Menaul type tank.

The Court: You analyzed it, and this is what it had in it? A. Yes.

The Court: This really is the explanation of it, you made a synthetic acid in this way, and you are going to show the results?

Mr. Owen: That is right.

The Court: That is all you claim for it? A. Yes.

The Court: All right. That is fair.

The Witness: In the first column the run number is 1-B. The acid was prepared, and contained 390 parts per million of lead, 2.79 parts per million of copper, and 1682 parts per million of iron. The figure for the iron is given

over under the fourth column, and samples were taken at the inlet, under parts per million of iron. It is the second sub-head under the fourth column. It is the average of two samples taken during the run. This acid was prepared and had those compositions, and then it was allowed to run from the crock through the tubing system that I described previously; and the samples of exit acid were taken and analyzed for iron; and the concentrations of iron in the exit samples are given in the fifth major column, the second sub-head, parts per million under samples taken at the outlet. The initial sample was 3250 parts per million.

The first composite sample was 1990 parts per million. The second composite sample, 2010 parts per million. The third composite sample, 1942 parts per million of iron. Calculating the grams of iron dissolved by the acid in passing through the pipe, there were 238 grams of iron dissolved from the piping system in the test.

The Court: That is, free iron? A. That is free iron. This is calculated as free iron. The weight of the iron dissolved from the pipe is actually that 238 grams. 238 grams is very close to a half pound. On the blanket run in this same tubing, that is the one with just the commercial acid without these added chemicals, and they are numbered 1-A and 1-AA, there were about two pounds of iron dissolved; and when we put those added chemicals in, it cuts it down to about a half a pound of iron dissolved.

Q. Will you take up your Table VI, PX-181, and explain it? A. Table VI is acid that was prepared to duplicate our synthetic Menaul acid prepared in our Menaul type tank. The run number is 2-B. The acid contained 316 parts per million of lead; 3.07 parts per million of copper and 2315 parts per million of iron at the inlet. We ran the acid through in the same manner, and the outlet samples, the samples leaving the end of the tubing system, initially showed 5970 parts per million; the first composite sample 2750 parts per million, the second composite sample 2770 parts per million and the third composite sample 2610 parts per million of iron. Calculating that into grams of iron dis-

solved from the tubing by the acid, it is 299.8 grams of iron dissolved, or again very close to a half a pound.

Q. Now, taking up your Table VII, PX-182, please explain it.

Mr. Lyon: Can I ask a question about Table VI. Is Table VI another run of this raw acid in a Menaul type tank? A. Oh, no. This was no Menaul type tank at all. It was run from a stoneware crock through tubing. That is all that was done.

The Court: That is what I thought.

Mr. Lyon: I understand your explanation to that effect, but Table No. VI is like Table No. V in that you determined the amount of copper and lead you added to the raw acid from your tests with the Menaul type tank, rather than from the directions given to you by Dr. Bartell? A. Oh, yes; that is correct.

The Court: He made this synthetically, and what he made it to was not something that Dr. Bartell had made, but something he had made by the experiment that we are going to compare, so far as it does compare, with the way the defendant treats and carries its acid. A. That is right; that is correct.

The Court: I have got the theory of your experiment.

The Witness: We wanted to find out whether that composition of acid, when separated from the lead plate and steel tank, would stop the corrosion of the tubing.

The Court: Where we got started wrong, in some way we got the idea that these had to do with the figures Dr. Bartell had given you, and you synthetically made up to what he had, and all we had to do was to disabuse our minds of that. A. In Tables VII and VIII we are going to take up that type of test.

Mr. Owen: Well, now, take up Table VII, doctor, and explain that. A. In Table VII, the composition was adjusted to the composition as reported by Dr. Bartell as existing in the average of samples he had analyzed of the defendant's acid.

Mr. Lyon: I want to just stop there. I have been

having trouble last night finding anything in Dr. Bartell's figures that corresponded to those the witness has given.

Mr. Owen: I will say it is not going to be claimed these exactly duplicate Dr. Bartell's findings. Let me explain. Mr. Rebbeck wrote to Dr. Prutton and told him what the averages of the samples taken from the defendant's wells were as to their metallic content. Dr. Prutton started from that point. Now, whether the actual amount in parts per million of copper and lead in Dr. Prutton's Tables VII and VIII correspond in the minutest detail to the number of parts per million Dr. Bartell's tests average up, I can't say, but I do say that the figures will show for themselves, if we compare Dr. Bartell's figures with these and they are a few parts over and under.

The Court: And we will be able to do that and if they are a little bit off, we will have to adjust them a little.

Mr. Owen: That is the position I take, Your Honor.

The Court: All right. Go ahead on that premise.

The Witness: Table VII, we have run 2-D. The composition of the acid was made up and the final acid before running it through the tubing contained 455 parts per million of lead, 3.7 parts per million of copper, and 418 parts per million of iron. The acid leaving the system, the initial acid out, contained 2295 parts per million of iron, 688 parts per million of iron in the first composite sample; the second composite sample, 697 parts per million of iron; and the third composite sample 669 parts per million of iron. The total amount of iron picked up by the acid was 195 grams. That figure is somewhat less than I found in the iron.

The Court: Let me see, how did you get that 195, by actual weight? A. We actually count them, the volume and acid that has gone through in between taking these samples, and the increase in iron content.

The Court: Did you compute them separately for each one of those four figures of iron? A. We computed the amount of iron. We computed them separately.

The Court: You took that first gallon that went through and computed at that high rate? A. Computed

each one of them separately, and then we computed the other quantities of iron at the total volume of inlet acid, and the difference between the sum of these exit acid composites and of the inlet acid, that difference was the amount of iron dissolved.

The Court: Here is what I was getting at, not whether there was anything wrong about your averages. As I understand it, you didn't take an average of four at all, but you took the first run there, and what did that figure, 2995? A. Yes.

The Court: You took all included within the next three sample all at this average figure of 688? A. That is the figure of 62.7 gallons of acid which had run through at that time.

The Court: Then you computed all that ran through during the next three periods at 697? A. That is correct.

The Court: All at the other three periods at 667. A. That is right, and added them together.

Mr. Owen: Would Your Honor like to know how he converted these parts per million into grams?

The Court: Yes, I would.

Q. Will you explain that? A. We have a sample calculation. This is for run 1-A. It is in the report, on page 16, and at the time of taking the first composite sample the gallons of acid that had gone through the tube was 76½ gallons. And went from zero to 76½, and in the acid there was one hundredth of a milligram of iron per cubic centimeter of acid.

The Court: Yes. A. That is we recorded our analyses that way, not quite parts per million. It is a different method of recording. One hundredth of a milligram per cubic centimeter of acid, and that was the inlet acid. The exit acid contained 1.22 milligrams of iron per cubic centimeter, and therefore the difference came in with .01 and came out with 1.22, which was 1.21 milligrams of iron per cubic centimeter.

Now, if we take the total number of cubic centimeters that have gone through 76½ gallons, a gallon is 3785 cubic

centimeters, and 85 cubic centimeters, one gallon is 3785 centimeters, so we multiply the gallons times 3785 and we get the total number of cubic centimeters that have gone through during the time of taking the composite sample that we have reported here. That is the total number of cubic centimeters. Now, each cubic centimeter picked up 1.21 milligrams of iron, and therefore we multiply that by 1.21 and we get the total number of milligrams of iron dissolved by that 76½ gallons of acid running through, and then you divide by 1000 and we have the number of grams of iron picked up for that first slug of acid, 76½ gallons dissolved 350 grams of iron.

The Court: Then you did the same thing on the others and added them together? A. Yes, that is right.

Mr. Lyon: I am still somewhat in the dark on one question, to which I would like an answer. I am just trying to get an explanation of this, that is, the final amount of lead and copper as reported at the bottom of column 2, Tables VII and VIII, is quite different. If those are both based on something from Dr. Bartell, I would like to know what accounts for the difference.

The Court: To date, we are forgetting that it is from Dr. Bartell at all, as I understand. A. I would like to explain that difference. In preparing these acids and dissolving the chlorides in the acid, it was very easy to get the iron chloride in the solution, and we could get whatever we wanted in the iron chloride concentration. To dissolve the copper chloride and get an exact copper concentration was also very easy; and, as has been reported by myself and Dr. Bartell, the copper is the vital element in the inhibition. The lead contributes some inhibition, but it is not nearly as vital as the copper concentration.

The Court: But it needs the copper to do its own work, does it not? The lead needs the copper to be effective, does it not? A. The two cooperate, but just the extent of the cooperation is difficult to tell from any tests that have been made; but they seem to cooperate, both contribute an inhibiting effect, but the copper seems to be the

one that does the major part of the inhibiting. If we take the final mixture, if we drop out the lead and iron, the copper would almost do what all three do. In dissolving the lead chloride in the acid, it is not very soluble—the concentration that we do get is almost a saturated solution, and, therefore, it was very difficult to dissolve lead chloride and get exactly what we wanted in the final acid, due to that slow rate of solution. And we did not feel that if we missed the lead concentration by 50 or even 100 parts per million that it made a great deal of difference, because the lead, although it has an inhibiting effect, our laboratory tests had shown that going from 250 parts per million to 500 parts per million of lead did not change the amount of inhibition to any extent. Oh, maybe 1 per cent. And therefore, if we hit fairly close on the lead, if we got the copper exact, and hit fairly close to the lead, as close as we could due to the difficulty of getting it in solution, and the iron is immaterial, but we could hit that whatever we wanted to, because it dissolved readily, and the lead is the one we couldn't get exactly what we wanted, due to this difficulty in soluble effect, and therefore the lead will differ. And so the figure that was given to us as the composition of—through Mr. Rebbeck, the average composition of defendant's acid as found by Dr. Bartell, as I stated, as he stated in his letter, 3.8 parts per million of copper. Well, on run 2-E, which is in Table VIII, the acid was exactly 3.8 parts per million of copper. In run 2-D the acid was 3.71 parts per million of copper which was substantially identical. The lead, however, in run 2-D was 455 parts per million, whereas in the analyses it was lower than that. I don't recall the exact figure. The amount that we had in run 2-E was 340 parts per million of lead. But our laboratory tests and the tests of others indicated the lead to be varied from 250 parts per million to 500 parts per million and the corrosiveness or inhibition of the acid was substantially identical.

The Court: Now is that true without the presence of copper, or in any acid with the presence of copper? A. It is substantially true whether there is copper present or not.

Mr. Lyon: Your Honor please, I would like to call your attention, while you are considering that, to one thing. The witness, as I understood his explanation to you, said the significant thing was the amount of copper. And you could disregard the lead.

Mr. Owen: No, no.

Mr. Lyon: Well, not disregard it, but—

The Court: But small differences.

Mr. Lyon: Yes. Well, now, I call your attention to Tables VII and VIII. They have apparently almost the same identical amount of copper, and yet the rate of corrosion in Table VII seems to be almost twice that of Table VIII, so there is something wrong here.

The Court: He hasn't got to explaining that. I could draw, probably, the same conclusion you have, to just look at it, but I am not going to until I hear what he says about it.

Mr. Owen: If I can get along, first I want to explain this matter of Dr. Bartell's sample that has been questioned, and if Your Honor will turn to your Exhibit PX-169 and go over to the right hand portion, under the heading "Truck Acids," it gives in that, under the heading, first the Stella Wilcox, then the Zahn and down below, in the separate column, the Crawford, and over to the left of the exhibit, the first line is copper. The first figure of 15 grams, or 3.6 parts per million, shows how much copper there was in that Stella Wilcox sample. And then to the right of that, under Zahn, 13 grams or 3.1 parts per million, was how much copper there was in the Zahn sample. Then if you drop down under Crawford in the first column it shows 20 grams or 4.8 parts per million. The average of all three copper contents is 3.8 parts per million. The amount of copper in Dr. Prutton's Table No. VII is 3.7 parts per million, and that in his Table No. VIII is 3.8 parts per million, so that is about as close as anyone could be expected to get.

Now under the lead content, the second line of figures, under truck acids, is the Stella Wilcox, lead 1700 grams or

417 parts per million; under Zahn 1800 grams or 435 parts per million; and under Crawford is 220 grams or 53 parts per million, and the average of those is 301 parts per million. Dr. Prutton's Table VII has 455 parts per million of lead and his Table VIII has 340 parts per million of lead.

Now, if you look at the next line below it shows the iron content, and under Stella Wilcox it was 1900 grams or 473 parts per million; and in the Zahn 1500 grams or 380 parts per million of iron, and under Crawford it was 860 grams or 210 parts per million. The average of those was 354 parts per million. And in Dr. Prutton's Table VII he had 418 parts per million of iron, and in Table VIII he had 382 parts per million of iron.

Exhibit PX-160 is Bartell's own averages of these samples. Your Honor will see they are very close to Dr. Prutton's.

Mr. Owen: Now, Doctor, will you go on with your explanation of Table VIII? A. Table VIII, Run 2-E is reported. The lead content of the acid 340 parts per million, the copper content 3.8 parts per million, the iron content 382 parts per million. The exit acid leaving tubing system, the first composite sample, 550 parts per million. We didn't take the initial out. That amount was of such a small volume, although it may be high, is negligible in comparison with the total and the first acid sample includes that.

The Court: If you made that very small and part of it got over into this No. 1, that, of course, would bring that 550 a little higher? A. A little higher, yes. One gallon out of 191 gallons, no matter how high it is, practically makes no difference. The second composite sample, 508 parts per million of iron; the third 483 parts per million of iron; the total amount of iron picked up by the acid was 101.4 grams.

The question was raised as to why this figure was 100 grams and the other was 195 grams. The statement is made that the acids should give substantially the same amount of inhibition. When you have an inhibited acid and you compare the difference between percent of inhibition and 100 percentage, you get into small differences and you can

magnify interpretations to get a very erroneous picture. The picture that these tests present to me is, first, that we ran commercial 15% hydrochloric acid through the tubing and got a loss of about 2 pounds of iron; secondly, we ran commercial acid to which we added the metal contents, varied somewhat, we got from one-quarter to a half pound of iron—approximately that range. It is impossible to exactly duplicate the preparation of the surfaces of the tubing in each run, and therefore I do not believe that the figures given in this report are any more accurate than plus or minus 75 grams, or some figure like that.

In other words, that there is a variation between the preparation of the surfaces that has to be considered and therefore you should look at the thing in a broad way in taking into account the accuracy of the method and the variations that might occur in the preparation of the inside surface of 20 foot lengths of tubing. I really was surprised at the accuracy we really got in comparing these tests.

The Court: This is about a sixth of a pound? A. No, about a quarter of a pound. And the other sample of 195 is about .4 pounds, the other close to .5. So it is between ¼ and ½. All of these synthetic acids run in that range. So comparing these two—

The Court: From the corrosive standpoint— A. As I say, I don't believe that these results are more accurate than plus or minus 75 grams as the outer limit of accuracy and that here we got 195 and 101 grams as the amount of iron dissolved.

The Court: You dissolved much less iron. About half as much? A. That is correct.

The Court: So if it will do the other work it would be much more desirable? A. Yes.

Mr. Lyon: May I ask what that means, Your Honor? He says that his results might be off or not accurate by 75 grams. That would mean in the case of Table No. VIII that the results are inaccurate to what per cent? I mean what per cent could you say the test was accurate? A. No, I would say that the test—I have not tried to compute any

per cent accuracy because I don't think it is possible, but the interpretation of the tests you have to include a consideration of the variables that are involved in the test, and I would say that this particular test, the actual amount of iron dissolved I am sure is 100 grams or very close to that at least. It might be somewhat more. We did not include the initial sample, due to some error. That would have stepped up a little bit the iron and it might be 150, or something like that. Actually in the weight loss of the tubing it was closer to 200. We weighed the tubing, and in this check we got this 101 grams dissolved in solution by our analysis, but when we weighed the tubing the loss in weight of the tubing was closer to 200 grams, so I would say it was somewhere from 100 to 200 grams of iron dissolved. The average would be about 150.

The Court: It is sort of an experiment if you wanted to check yourself by running two experiments you would have to rig up the thing the second time? A. Yes.

The Court: You couldn't keep using that over and over, the same tubing? A. We used the tubing over and we have data to show that. We have run a series of laboratory tests with this 1¼ inch tubing, running one run with an acid and getting the inhibition or corrosiveness of the acid, then taking it and putting it through this cleaning and brushing operation and running it over again, and we can check with that reuse of the tubing, we can check within about 10 per cent, within about 10 per cent.

The Court: Do I understand you have performed experiments that would be duplicates of this here? What I had in mind was as to your frank statement as to accuracy. I was wondering if I was to understand from that that it is your opinion that if you tried to run the very same experiment there during several times there would be— A. Differences.

The Court: A difference. Then it gets down to about what per cent? A. Oh, it is about 10 per cent.

The Court: Isn't that what you were asking?

Mr. Lyon: Yes. Although of course an error of 75

grams in the case of Table No. VIII would be bigger than a 10 per cent error. A. That isn't the statement, or else I made it wrong. I don't believe that 100 grams could be 25 per cent, I don't think that. It was actually 101 grams increase in iron as determined by analysis. That is fixed. But there might be more dissolved than that, somewhat more, and it might be 75 grams more. That is about what I meant.

Mr. Lyon: You made that statement which puzzled me last night, that you find more loss of iron on weighing the pipe than you can find present in the acid in all these tests? A. I will tell you why that is true, because before re-weighing the pipe when we clean it out the inside surface will rust slightly, and very rapidly after washing with water, and we ran that reamer in and dried it again and it took out a little loose iron, and we got more iron out, so the weight loss, we do not rely on that.

We can absolutely rely on these chemical analyses as being within 10 per cent of the figures, and we are talking here about 70 and 80 per cent reduction of corrosiveness, and 10 per cent on that is not a major factor, in a practical sense. If we were down talking of 10 per cent inhibition, 10 per cent would be a major factor. We are talking about 60 and 80 per cent.

Mr. Owen: In your Table VII, the total grams increase in iron which you gave at 195 includes the iron that came out in the initial out gallon of acid, and in the Table VIII the figure of 101.4 grams does not include that, is that correct? A. I would have to check on that. I believe that is the way it was done. As I said before, the concentration in the initial out, since it is only one gallon of acid, is a negligible amount, as a rule, and I wouldn't want to rely on that difference in the report here to indicate that that was the cause of the difference. It might account for a few grams, but it wouldn't be a major thing.

Q. Now, I wish you would in connection with Tables V, VI, VII and VIII do what you did in connection with Tables I, II, III and IV, that is, compute the loss, the

average loss of weight per 100 feet per hour of contact between the acid and the walls of the pipe? A. In Table V, run 1-B, the tubing lost 64.4 grams of iron per 100 foot of length per hour of contact. In run 2-B, the tubing lost 84.6 grams of iron per 100 foot length of tubing per hour, and the average of those two, 84.6 and 64.4 would be 149 over 2, which would be 74.5. Then in run 2-D the loss in weight was 59.3 grams of iron per 100 foot length of tubing per hour, and in run 2-E it was 29.4 grams of iron, and the average of those is 44.4. The average of the averages is 59.4.

Q. And the average of the average in connection with the first four runs is 264¼? A. Yes.

Q. Now, can you explain in some way the relative rates of corrosiveness indicated by those two sets of runs, the first four being without an addition of copper or lead, and the second four being with additions of those metals? A. Well, if you take—

Mr. Lyon: I am going to object to that on the ground it includes the result of Table No. VIII, which is admittedly way out of line, because there was no initial sample taken, and the result almost 100 per cent below No. VII, which had the initial sample, and on the witness' statement, as it contains the same amount of copper, that it should have the same value, so where we are averaging figures in here that are admittedly wrong it should be excluded.

Mr. Owen: I object to the statement that the figures in Table VIII are admittedly wrong. The witness has explained that the figures in any one of these tables are not stated to be accurate to the last degree, and they were all made in the same way, the tests were made in the same way, and the analyses were made in the same way, as I understand it. A. That is correct.

The Court: Well, I will let it go in with your criticism of it. You may put that in.

A. Well, if we take the corrosiveness of the first four runs of commercial 15 per cent acid as 264¼ and the average of the last four runs with the added metals as 59.4,

why the commercial acid is 264 divided by 59, or the commercial acid is 4.46 times as corrosive as the synthetic acid. The average of these four—

The Court: Do I understand from the eight, however, there is omitted from that all that ran through in the first twenty minutes? A. That is not omitted.

The Court: You took these samples every twenty minutes? A. Yes, but the initial sample was taken in the first gallon that came through. The first single gallon that came through, and then the average sample was taken over that twenty minute period, and including even that first gallon.

The Court: One gallon? A. Yes. It is a very small amount and it has very little significance.

The Court: While it is high, in a gallon there couldn't be very much? A. Out of 180 gallons that we ran through.

Mr. Owen: Doctor, how much difference would there be in the figure you have given in your last answer if you omitted Table VIII entirely and took the average of Tables V, VI, and VII for the runs in which you added lead and copper?

Mr. Lyon: My point is, Your Honor, these averages seem to me have to be scrutinized very carefully, because when you average two tests that are almost 100 per cent apart, why you are taking quite a liberty with an average.

The Court: I recognize that.

A. If you take the average of the first three tests, omitting the test described in Table VIII, the average amount of iron dissolved was 69.1 grams per 100 foot length of tubing per hour of contact. That is compared with 59.4 grams loss if you take all four and average them, and the raw acid, or the 15 per cent acid, the number of times more corrosive than that is in the acid of the first three would be 264¼ divided by 69.1, which is 3.83, so it is 3.83 times as corrosive, so taking either the first three, or the four, and averaging them up, the corrosiveness of the raw 15 per cent acid is about four times as great as that of these acids to which the metals have been added.

Q. What was the size of your tubing you used in these

tests? A. The tubing that was used was standard inch and a quarter oil well tubing.

Mr. Lyon: May I ask you how much it weighed per foot? A. I think that is in the report. It is right on the first page of the report. Page 3, the first one and a quarter inch oil well tubing, external upset, range 1, 2.41 pounds per foot of length.

The Court: I don't know if I got an answer to my question. This bears the date June 20, 1941. Were all of these things done prior to that? A. Yes.

The Court: They were all done before that, and then you made up the report? A. Yes.

The Court: And shortly before? A. Yes.

The Court: I don't care about, as far as I am concerned, the exact date, but this date here is after you got through all of this. A. That is correct.

The Court: You tabulated this. A. Yes.

The Court: All right.

Mr. Owen: Now, I would like to offer the report as PX-184. The offer includes all of the other PX's which have been identified in the report.

The Court: Well, I will admit that. The entire report of June 20, 1941.

(Dr. Prutton's report of June 20, 1941, was thereupon marked PX-184.)

Mr. Owen: Doctor, what is the size of the tubing used in oil wells generally? A. Usually it is about two inches.

Q. Can you compute what the loss of iron would be in 1,000 feet of 2 inch oil well tubing, taking as the rate of loss the average of your first four tables, I, II, III and IV, which you gave as 264¼ grams from 100 feet of 1¼ inch tubing with contact between the acid and the tubing for one hour?

The Court: Just on the inside.

Mr. Owen: Just on the inside. A. Just on the inside. The inside area of 2 inch tubing for 1,000 feet is about 540 square feet. The inside area of inch and a quarter tubing, 1,000 feet long, is about 340 square feet. So if we multiply

264¼ by 10 we get the amount of iron that would be dissolved from 1,000 feet of inch and a quarter tubing in one hour, and then if we multiply that by the ratio of the area, inside area of the 2 inch tubing to the inside area of the 1¼ inch tubing, we would get the amount of iron that would be dissolved from 1,000 feet of 2 inch tubing, and if we do that the figure comes out to be about 4200 grams. 4200 grams of iron would be dissolved in one hour from 1,000 feet, the inside of 1,000 feet of 2 inch tubing.

Q. And that is about 9.3 pounds of iron would be dissolved in one hour, 4200 grams.

Mr. Lyon: Do you have what per cent of the weight of tubing that is? A. No, I do not.

Mr. Owen: Now, in what form would that iron go down into the well? A. Well, it goes down as a mixture of ferric chloride and ferrous chloride.

Q. What action would those ferric and ferrous chlorides have in the well if they got into the formation?

Mr. Lyon: Well, I object to that on the grounds there is no foundation laid. I mean he is not entitled to express an opinion unless he is qualified. He hasn't testified to any knowledge of oil well formations or any experience with them, or anything of the kind.

The Court: I will overrule the objection. A. A solution of acid containing an appreciable amount of ferrous chloride or ferric chloride contacting calcium carbonate, which is the main ingredient of limestone, the ferric chloride would precipitate as ferric hydroxide and there would be a tendency to plug up the pores of the formation due to that precipitation. The ferrous chloride would have some effect upon the viscosity of the solution, making it a little thicker if it were present, thus retarding its entrance into the formation. In forming the ferrous chloride some of the acid has been consumed, and therefore the acid concentration would not be as great as it should have been. That is, as great as 15%, which is the concentration usually forced into the top of the well.

Mr. Lyon: I don't understand that. How much did

you say the concentration was reduced in this particular instance that you are testifying to? From 15% to what? A. It would be reduced—I haven't figured that out. I can figure it out.

Mr. Lyon: I would like to know what you are testifying to. I would like to know whether that is a significant quantity or not. In this example you have given, how far would the concentration be reduced? From 15% to what? A. Well, this calculation wasn't made for the intent of showing any exact reduction, but if we take a typical oil well, which is usually a couple of thousand feet deep, and give some contacts of the acid of 15 hours instead of one hour—

Mr. Lyon (interposing): No, take two hours. A. Well, multiply 3 times 15, and we get 45 times as much corrosion.

Mr. Wiles: This is not cross examination.

The Court: This is so complicated, maybe you better wait. I am glad to have it, but I think there is some other little thing that is involved that you can bring up in cross examination.

Mr. Owen: Doctor, you have referred to tests you made in a tank, or placing acid in a tank which you have referred to as duplicating the Menaul tank. Will you explain what tests you made, how you proceeded. And in that connection, I believe you have a report. A. Yes, I have a report of the tests.

Mr. Owen: I will hand up a copy of this report to the court so the testimony will be followed and will give a copy to defendant counsel (handing same to court and counsel).

Q. I think first, Doctor, I will ask you to explain the construction of the tank which you made. A. We prepared a tank, a steel tank of 240 gallons capacity, duplicating as close as we could the important details of the construction of the Halliburton truck tanks from the information received from Mr. Rebbeck of The Dow Chemical Company. He supplied us with a drawing of the tank, a statement as to the material the tank was made of, a statement as to the

relative area of lead sheet in the bottom of the tank to the area of the inner surface of the truck tank, and as to the composition of the sheet lead used, as well as the methods of assembling the sheet lead into the steel tank. From those instructions we prepared a steel tank which is described in this report. The tank was 34 inches square by 50 inches tall.

Mr. Owen: May I interrupt just a minute. I think, Your Honor, I will have this report identified as PX-185, and then we can refer to pages.

The Court: We will call this whole report PX-185.

Q. Now, what page are you referring to? A. Page 3 is a description of the tank that we prepared.

Q. And where is that tank illustrated in the report? A. On page 14 there is a side view of the tank in position for the runs, page 14, or Figure 2.

Q. Page 14 is a photograph in my copy. A. That is a photograph of the tank. Figure 3 on page 15 shows a sketch of the tank and shows some of the details of fastening in of the lead sheet on the bottom.

Q. You might explain that. A. That figure 3 should be viewed in the other direction. If you hold the report on the side, the bottom of the tank is down here (indicating) and this upper edge with reinforcing rim is on the top. The tank was prepared from manufacturer's Grade A steel plate ¼" thick and was fabricated for us by the J. T. Ryerson Company of Cleveland, Ohio. The tank was electro-welded. The inside of the tank was cleaned by sand blasting. And then a sheet of chemical grade lead was fastened inside the tank on the bottom. The sheet of lead was burned into a strip of steel, as described on page 3, on opposite sides of the lead sheet which was 33 inches square and ⅛ inch thick, two strips of No. 10 blue annealed steel, three inches by 33 inches, were fastened to the edge of the lead sheet by burning.

The Court: What was fastened to the lead sheet? A. Two strips of No. 2 blue annealed steel. Just thin sheet steel.

Mr. Owen: Does that appear in that Figure 3? A. That is the heavy horizontal line.

Q. The steel is in an "L" shape, is it? A. The steel, as I recall, was in a flat sheet, and this figure isn't quite correct as I recall. I can find out in just a moment, if I could ask my assistant.

A Voice: It was "L" shaped. A. It was an "L" shaped piece. It was not just a flat strip. That is right.

The Court: The sheet right at the corner? A. The sheet right at the corner.

The Court: Extending up along the side and a little ways out on the bottom. A. The lead sheet was burned to the bottom part of that "L" and then the "L" of this blue annealed steel strip was welded onto the side of the tank at three points, in order to tack it onto the side of the tank. So the upper half of this strip at three points across there, the strip was welded onto the steel tank.

The Court: Does the lead extend up along the side at all? A. No.

The Court: The lead is just on the bottom? A. On the bottom, yes, and this "L" shaped strip of steel was burned to the lead, and it was spot welded onto the side of the tank in three places. Now, the tank, before use in these tests, was polarized, or that is the term used by the Halliburton Company for this operation. As stated in letters from Mr. Rebbeck, the Halliburton Company polarizes their truck tanks. They prepare the tanks.

Mr. Owen: Your Honor will recall, that was in Mr. Edwards deposition, which was read into the record.

The Court: Yes, I remember. A. They prepare the tanks when they are new with the steel and lead sheet assembly, and then they fill the tank with acid, and into the tank, the top of the tank, they insert a strip of sheet lead, and they connect that sheet lead with the positive pole of a lead storage battery, and they connect the tank with the negative pole of that storage battery, and they electrolyze the contents of the tank, and with the idea that after allowing the storage battery to become discharged by

standing all night and current passing through the acid in the tank, that the tank is polarized.

The Court: Polarizing, you mean a positive and negative, is that what you mean? A. Polarizing is a term that has a very vague meaning. That involves mostly any kind of effect that reduces the voltage of an electro-chemical cell. In other words, if you have a battery and something happens to it and your voltage goes down, then they say it is polarized, or if you are electro-plating and putting a voltage into the cell and the voltage goes out, they say it is polarized. In other words, it is a general term that indicates something has happened to disturb the voltage relationships in a cell. It is a vague term and covers many types of things. For example—

The Court: The north and south pole are the positive and negative, and the electricity does some vague and indefinite thing, that is what you are referring to by polarizing? A. Yes. It refers to that, but it primarily refers to the voltage of the cell. That is the more scientific definition.

The Court: It loses it all if it gets it? A. If it is a battery that is giving out energy, like a storage battery that you have in your automobile, anything that reduces your voltage is called polarization, because it is reducing the effectiveness of the battery, but if you have an electro-plating operation, that cell is absorbing energy from the generator. If something happens that increases your voltage, its efficiency is lowered, then they call that polarization. It is a very vague term and its use in this particular case is simply another name for lead plating the inside of a tank. That is all it is. It is just used in a loose sense. What happens is that the lead dissolves from the strip of lead which is put in the tank and plates out and covers the steel up more or less perfectly.

The Court: But you have got a steel plate in there that is the other pole? A. That is the other pole, and then the dissolving—

The Court: You don't rely on just the steel of the tank? A. No.

The Court: But when they say they polarize— A. They have the two poles, the lead strip and the iron tank, and the lead dissolves from this strip and plates out on the tank and coats over the steel.

The Court: Is that a strip of lead? A. This is a strip of iron that we fasten the lead sheet into the tank. This is the side of the tank. This lead sheet is down at the bottom. The strip comes up like this and it is fastened to the bottom, the lead sheet is in the bottom.

The Court: It doesn't cover the whole bottom? A. It covers the whole bottom.

The Court: The whole bottom is covered? A. Practically the whole bottom. When they prepare these tanks they have the lead sheet in the bottom. That will save it all the time, but they fill the tank up with acid and then they put another lead sheet in the center of this acid.

The Court: Down into it? A. Down into the center. Figure 4 shows this polarizing assembly. They put a lead sheet in there. They fill the tank with acid and put a lead sheet into it and then connect the lead sheet, this added lead sheet. That is taken and connected to the positive pole of a storage battery, but not while it is in use.

The Court: You say not while it is in use? It is while it is doing this polarizing? A. That is only done once. That is only done when they first put the tank in service, as I understand it.

Mr. Lyon: The tank is only polarized once?

The Court: Everywhere there is steel there is a tendency to do that. A. They plate lead on to it.

Mr. Lyon: In other words, you don't have to use your acid going into the well to accomplish that result. They do it in the beginning.

The Court: I guess it is a part of the building of the tank, if you want to think of it in that way.

Mr. Lyon: That is right. They lead plate the tank in the factory, or before they put it in service, otherwise they would have to be using the well operations in lead plating the tanks.

The Court: All right. But this is once in a lifetime? A. Just in the beginning.

The Court: What it does is to put a lead coating on there? A. Partially.

The Court: And we can think of that as being done and that acid taken out? A. That acid is taken out and then the tank is ready for use.

The Court: All right.

Mr. Owen: Then this lead sheet which is suspended in the tank in Figure 4 is also removed? A. That lead sheet is removed and the lead sheet in the bottom stays in there.

The Court: That lead sheet is all over the bottom, as I understand it? A. Yes.

The Court: Will you agree to that?

Mr. Lyon: I think so, yes.

The Witness: The tank was 34 by 34 and the sheet was 33 by 33, so it substantially covers the whole bottom.

The Court: That explains where I got the idea it did not cover the whole bottom, but it pretty nearly does. You cover the whole bottom? A. 33 by 33 we used.

The Court: You followed the same proportion? A. Yes.

Mr. Lyon: I understand there is a man here that operates these tanks and he says these sheets do not cover the entire bottom, but they very nearly do.

The Court: That is what he did.

Mr. Lyon: There is a certain ratio of the area of the surface of the lead to the surface of the tank, which we will have to give you the formula for. A. We had to use that same ratio as close as could be calculated from the drawings of their tank.

The Court: Now, I haven't yet got—I understand the tank is a steel tank? A. Yes.

The Court: Now, you add the piece of steel, but I haven't got that through my head yet.

Mr. Owen: The only purpose of that is to hold the lead in place.

The Court: That is the only purpose? A. Yes.

Mr. Owen: It holds the lead in place and makes contact between the lead and the iron of the tank, electrical contact.

Mr. Wiles: That was explained in one of the depositions. They said it was too difficult to solder the lead inside the tank.

The Court: As to this plating operation, if they could have held it without anything it would have been plated just the same? A. Oh, yes.

The Court: It has no purpose, only as a holder? A. That is right.

The Court: And in making the holder they make it of steel? A. Yes.

Mr. Wiles: The lead could be just as well soldered or burned into the tank direct, only some man would have gotten inside, and it was a hard job to do it.

The Court: Well, all right. Now, I have got my tank straight.

Mr. Owen: And the sheet of steel at the bottom of the tank stayed there permanently? A. Well, the strips holding the lead stay there permanently.

Q. I mean the sheet of lead stayed there permanently in the bottom of the tank? A. Yes.

Q. And the suspended sheet of lead used during the polarization is removed after that operation? A. Is never used again.

The Court: Will you give me some idea how thick a coating that is, what that means, a little bit more, on that tank, that lead plating? A. It isn't very thick.

The Court: It is nothing I can see if I look at it? A. I think you could. If you wiped it, it would probably come off, partially.

The Court: Lead is soft so it will come off. A. It will not be any major thickness, I don't believe.

The Court: A thousandth of an inch? A. Might be a few thousandths. It isn't a continuous coating. Part of the lead plating never continuously plates over the steel, so there are little holes through it that the steel is somewhat

exposed, but there will be just some particles of lead covering most of the surface. The exact thickness of that would be difficult to say, but it is probably a few thousandths of an inch.

The Court: Maybe I am anticipating again, but are you going to account for anything that happens by this lead coat that is on there to start in with, is that going to enter into our problem? A. Not as a major factor.

The Court: All right. There is an awful lot of surface of that, if we are looking for a lead surface. A. That is correct.

Mr. Lyon: That enters into the protection of the tank, doesn't it? A. The protection of the tank.

The Court: But I am wondering if now, in this, they are going to now talk to me about and have been talking to me about the inhibition that comes from copper and lead, and I am wondering whether you are going to explain in any degree or take into account in any way that lead that is already plated onto the walls of this tank in connection with that other subject I have got to think about, which is the big subject, on infringement.

Mr. Lyon: The plaintiff here is talking about the action on the pipe down the well. The primary purpose or the real purpose of our lead, bonded lead in the tank, and the action in the tank, is to protect the tank. That is the real purpose of the Menaul system, is to protect the tank.

The Court: Yes.

Mr. Lyon: What it does down to the pipe is another thing.

The Court: What they claim is that your system puts inhibition into the solution.

Mr. Lyon: They say we get some copper in and that copper really protects—

The Court (interposing): And lead.

Mr. Lyon: But they say it is really the copper that does the protecting.

The Court: Yes.

Mr. Lyon: Down the well.

The Court: They give some credit to the lead.

Mr. Lyon: Yes. But as I understand the witness the lead is a minor factor. A. Well, it may be one-fifth, if there is copper or something like that.

The Court: Let's find out right now, before we get into this, whether there is any claim that this lead that is plated onto the walls of the transportation tank enters in in any way, that plated lead enters in in any way into the claim of inhibiting the acid.

Mr. Owen: Well, I think it does, Your Honor.

The Court: Well, all right then. That is what I want to know.

Mr. Owen: My understanding is that the acid placed in that tank after it has been polarized not only dissolves lead from the lead plates in the bottom but it also dissolves lead from the walls of the tank.

The Court: I want to know what to watch for.

Mr. Owen: And that both of those are sources for the lead which is found in the treating acid. That is your understanding, Dr. Prutton? A. I think some of it comes from the sides. It is so indefinite as to the amount I can't tell how much of it comes from the sides.

Mr. Lyon: I would like to state our position so the court may have it in mind. The purpose of our system is to protect the tank. They polarize the tank to get this lead plating on it to start with. But if they didn't have this lead in the tank bonded to the steel, that lead on the walls would come right off in a short time. And, therefore, they have to have this other lead plate in there, which continues to keep it.

The Court: As I understand it, wouldn't it continue it? A. Very slightly. It would continue to some extent.

The Court: And keep it from coming off, against the taking of it off?

Mr. Lyon: We will show Your Honor how long the steel tank would last even if we polarized it if we didn't have that lead plate bonded in there to keep up the polarizing action.

The Court: I guess I have it all in mind.

Mr. Owen: I would just like to read from the opening statement of counsel, which seems to me is not entirely consistent with what he has just stated that the only purpose of this lead plate so far is to protect the tank.

Mr. Lyon: I didn't say that.

Mr. Owen: This is what he said in the opening statement: "Now, as to our method of protecting our pipe, we don't add any chemical, don't add any arsenate, don't add any chemical at all. We have an electrical method of protecting the pipes. Certainly that raises an entirely different question of infringement than anything they had in the Williams case where the defendant was adding one of the very materials mentioned in plaintiff's patent. Here we have an electrical method and it is covered by our own patent."

Mr. Lyon: Now read the rest of it.

The Court: I don't understand the change from that.

Mr. Owen: That is the end of it.

Mr. Lyon: Oh, no, it isn't. I explained to the court that theoretically the electric current, on a theoretical basis, may aid in the protection of the pipe down in the well, but that that was theoretical and could not be demonstrated.

The Court: You continue the battery during the transportation?

Mr. Lyon: That is correct.

The Court: I don't see why the same operation, leaving the tank, wouldn't tend to continue to do it.

Mr. Wiles: Did you say he continued at all times the battery?

Mr. Lyon: We have the lead bonded to the tank and keep the battery action going while the acid is being shipped out to the well.

The Court: But you don't have an outside battery?

Mr. Lyon: Don't have any battery.

The Court: Pumping on it like you did when you plated?

Mr. Lyon: That is right.

The Court: All right.

Mr. Owen: We will go into that question further later in the case, Your Honor.

Mr. Owen: Now, doctor, will you state how you proceeded when you made a run through your pipe system utilizing this polarized tank? A. The set-up of the system that we used in these tests is shown on page 17 in this report, in Figure 5. We mounted the stoneware crock, which I have described before in the former tests, on the balcony of the large laboratory, and from the bottom of that crock we have Pyrex tubing that would lead the blended acids in the crock, and we had them at the correct composition, would lead them into this Menaul tank. You might conceive that this stoneware crock is something like a storage tank in the actual field operation of this Menaul process, that the acid is diluted and then dumped into the truck tank which corresponds to this steel tank of ours.

The Court: Now, your theory was you are getting acid in this stone crock as near as you could, as you understood it, like the acid when it was dumped into the transportation tank?

Mr. Owen: Yes, like the acid after it was placed in the transportation tank, and diluted to 15 per cent. We placed in this stoneware tank a 15 per cent solution of hydrochloric acid.

The Court: I had forgotten the water. So far as anything else that is in the acid other than the water to dilute, there was nothing else placed in it? A. Nothing else added, it was simply 15 per cent.

The Court: It was like it was and in other words commercial acid, as they say at that time? A. Yes, that is all. We added nothing in the tank except water to the commercial acid. The general method of the test was to dilute the commercial acid to 15 per cent concentration with tap water in the stoneware crock. Then after analysis and making certain that that acid was satisfactory to employ in the test by running the hydrochloric acid concentration and the corrosiveness of the acid as compared with C. P.

acid, that acid was then run into this Menaul type steel tank which had previously been polarized and washed out after polarizing.

The Court: That has got the lead in the bottom and it has got the plating lead plated as near as you can do it like the defendant's tank, transportation tank is lead plated when they get it in?

Mr. Owen: Yes, Your Honor.

The Court: The only difference in the whole thing is that they have their water in this tank and then let that run in, and you put the water in above?

Mr. Owen: That is right.

The Court: So instead of my saying when you dumped it in I will say right after you dumped it in you got just what you understand they have right after they put their acid in? A. That is correct.

The Court: Both as to tank and what is in the tank. I am ready to go. A. The acid was stored in this tank before it was dumped into the steel tank, and it was adjusted to 85 degrees Fahrenheit, and was kept at that temperature in the steel tank as well, so we are running at 85 degrees Fahrenheit, just as we did in the former runs.

The Court: Well, now, that is a little bit hotter than theirs will be, unless it was last week. Last week that would be a little bit too cold for them, probably. I am just thinking. I am trying to compare everything as I go along. They probably didn't have theirs 85, did they?

Mr. Conner: If Your Honor wants to compare those particular temperatures that Dr. Prutton is running, against the actual weather temperature in this state and in the county of Ogemaw for the days on which those wells were treated, if you say so I will get those for you next week.

The Court: That was the reason they took it?

Mr. Conner: I don't say that, but I merely state I have the weather reports for those days on which these wells were treated, August 2nd and 5th, which were very hot days, as I recall it, it was up in the 80's and 90's, and

September 10th was a very hot day and it was up in the 80's all of 1938.

Mr. Lyon: It is not a question of what the temperature is in the air.

The Court: This is hotter for some reason or other than I would expect to find if I put a thermometer into one of the tanks. A. Down in the well it gets hotter.

Mr. Owen: You take a steel tank and run it several hours in the country with the sun shining, it is much hotter than 85.

The Court: You couldn't get any temperature but what somebody could complain about it.

Mr. Lyon: Are they contending that there is some significance, some infringement here, because we acidized in the summer?

Mr. Owen: No, we say that you are infringing both summer and winter.

The Court: The doctor had to take some temperature and it is fair of him to tell us what he did take.

Mr. Lyon: The point is he maintained a particular temperature in this tank by using some heat, whereas the defendant, I don't think there is any dispute, does not add any heat to its tank.

Mr. Owen: No, we don't claim that.

Mr. Lyon: It is the temperature of his tank, it is whatever it will be because of atmospheric conditions.

The Court: If he hasn't taken it at all you probably will be saying you don't know the temperature. We can readjust from that. We know and I am glad we do, what temperature he has. A. I think 85 degrees Fahrenheit is very close to the bottom hole temperature of any wells in Michigan, and that was one reason for that.

The Court: I got an idea it was a lot hotter. A. I don't know. It is sort of an average temperature.

The Court: All he can tell us is what temperature he did use. A. This acid was run into the steel tank and agitated periodically with a glass, heavy glass rod for a period of six hours. Just stirred it every fifteen minutes with a

glass rod for a period of six hours, which we felt would duplicate in some manner the contact time and the amount of agitation that acid being transported in a Menaul type tank truck would get in being taken from a storage plant to the well.

The Court: And you are stirring it also as near as you could come to the agitation it would get by being hauled? A. I don't think it duplicates it.

Mr. Lyon: I think these roads are rougher than fifteen minutes stirring out in the oil field.

The Court: But they stop and stand. A. After standing in the tank, the acid standing in the tank, the contents of the tank was then siphoned through this tubing system that we have previously described. Now, we had to, in order to get it out of the tank without running it out of the bottom discharge in the tank, we had to siphon it, and shown above the tank is an arrow indicating a vacuum supply. We had a vacuum pump connected with that, and that vacuum pump went into a large Pyrex bottle, which is shown as a rectangle just directly above the steel tank, right at the top end.

Mr. Owen: Shown more clearly on page 18, Your Honor. A. That is correct. The vacuum was maintained in order to keep the piping system full of acid at all times. It was siphoned through the piping system, but to fill up the tubing to start the siphoning action we had to apply the vacuum at the beginning and fill the entire system up with acid, and then start the siphoning action, and we had to maintain that periodically, to apply the vacuum, in order to remove any hydrogen gas which was formed during the dissolving of the iron by the acid running through it. Hydrogen bubbles would accumulate which would break the siphon action, so the hydrogen was removed through this vaccum pump, and we maintained a level of acid up into the bottle at the level mark N on the bottle here, and in that manner maintained the siphoning action continuously, and the oil well tubing was always full of acid.

The acid was run through the tubing system at the rate

of ~~100~~ one gallon per minute, and adjusted as we have described previously. The two different types of tests were made, first tests which follow the teaching of defendant's Menaul patent, U. S. No. 2,149,617. We connected the wire from the truck tank or the Menaul type tank to the tubing system to make electrical connection between the two, and ran several tests in that manner following their patent. Then we ran also several tests in which we disconnected that wire to break the electrical circuit and prevent any electrical action, and the results of those tests are described in the tables that are contained in this report.

In Table IX, run 1-M, we used the Menaul type tank and the acid was in the tank in this case six hours and 33 minutes, agitation, and then the acid was run over through the tubing at the rate of one gallon per minute, using Series 1 tubing. The average analysis of the acid leaving the Menaul tank was 3—

The Court (interposing): That is at the end of the pipe? A. That is at the inlet of the pipe. That is this steel tank, duplicating the truck tank. That is the inlet.

The Court: When you started? A. When we started up in the stoneware crock, the acid contained substantially no lead or copper, and was substantially as corrosive as C. P. acid. Then we ran it into the tank truck and agitated it for six hours and picked up lead, copper and iron, and these are the concentrations of the acid we took with that simulated truck during the run, and we analyzed for the metal content of the acid run through the tubing.

The Court: Your thought being that this was the condition of it and the content of it as at the time it started into the tubing and you are trying to show by that what you think it would be at the time it started into the well. A. That is correct.

The Court: All right. I follow you. A. (continued): 362 parts per million of lead, 4.3 parts per million of copper, and the content of the iron varied considerably during the run, and we took a number of samples out of the Menaul type tank during the runs to get more—a better

picture of the iron content because the iron is an important element in determining the amount of iron dissolved from the tubing. And so you find under the heading of "Samples Taken at the Inlet," that means acid taken from the Menaul tank just before it went into the tubing system, after it has been in there this six and a third hours.

We took samples while it was running out of this tank into the tubing, so we would get a better picture of the metal concentration, the iron concentration of the inlet acid to the tubing.

The Court: Well, now that tends to show that it was getting more iron into it. A. It picked up iron during the run.

Mr. Lyon: The rate isn't reported here. Have you got the amount of iron you found? A. Oh, yes, it is over under the heading of "Samples Taken at Inlet." You see the iron content of the tank was varying during the run. It was picked up. The acid was still picking up some iron from the tank, so we took samples every twenty minutes.

Mr. Lyon: Wasn't the copper changing, too? A. We took several samples, but the copper did not show nearly the extent of change that the iron showed, and this figure is the average of samples, and I can give you the individual or the composites of several samples that were taken.

Mr. Lyon: Did the lead change, too? A. The lead changed somewhat, too. These are the averages.

Mr. Lyon: I would like to have, so we can study it over the week-end for these different tests where there are averages and you have given only one figure—there are averages of different samples, I wish you would let me have the individual data. A. I will get those.

The Court: I know it shows a quite rapidly increasing iron content. That means iron chloride? A. That is correct.

The Court: And that means, doesn't it, that it was eating off of the tank at that rate? A. Yes, sir.

The Court: Or, at that increasing rate. A. Yes, sir. You see the commercial acid when diluted, the 15%, had

from 5 to 10 parts per million of iron. We dumped them all in.

The Court: What is there that shows how much iron there was in this when it got into the transportation tank before it— (Witness interposing): I have all those figures. They are not on this sheet. It was very low, 5 to 10 parts per million. We received no acid that had over 5 to 10 parts per million of iron. In the six hours of agitation it picked up from 1100 to 1200 parts per million.

The Court: Then one of the arguments is it did not protect that tank? A. It didn't protect it a great deal. It undoubtedly protected it over a steel tank but there was considerable amount of action on the tank.

Mr. Lyon: Could you tell us, also, in this tank whether there was any lead and copper in the raw acid? A. The analyses of the raw acid, which I have for all of the runs, show just fractional parts per million of lead and copper; all raw acid, and the iron content was never over 10 parts per million of iron, and only fractional amounts of lead and copper.

Mr. Lyon: But there was some copper and lead in the raw acid? A. There was, yes.

(Witness continuing): This acid entering the system had an average composition of 350 parts per million of lead, 4 3 of copper, and then a variable amount of iron as the run progressed. We analyzed the samples of the exit acid, the composite samples, and determined their iron content. And in the same manner that we used in the former tests of calculating the increase in iron content of the acid going through the tubing.

The Court: Now, this is the bottom of the tank? A. The bottom, second column from the right.

The Court: Comparable to when it reaches the bottom of the well. A. Yes.

The Court: I am not saying anything about how active it is, but that is the purpose of it.

(Witness continuing): And from the difference in iron concentrations and the volumes that had passed through,

we calculated the amount of iron that would dissolve from the tubing; knowing the amount that was in the inlet acid and the amount in the exit acid, the increase in iron content came from the tubing and that amount in this test was 322 grams of iron was dissolved from the tubing.

The Court: I think I know what your explanation is but that initial one again? A. Was the first gallon.

The Court: I think I know what your explanation is, but give me again why that is the highest of them all. A. Because in cleaning the tubing out there is always a few particles of loose iron it is difficult to remove, and the acid loosens those up and the iron runs down in the first slug of acid; the first small amount contains a higher amount of iron, usually, than the rest of the acid. Now, it is not essential that that be the case. In other words, it comes out when we clean the tubing. As I said before, it is impossible to clean out 112 feet of tubing.

The Court: What was in there you didn't clean out was free iron. That wasn't iron ferrous chloride? A. It was free iron but in a very small particle form and by the time it got down to the end the acid had dissolved it. We never could detect any metallic iron in the exit acid.

The Court: What is your explanation as to why—why is it we find an increasing one following that? A. I don't know. In this particular case in this one 1106 at the beginning, possibly we had removed all that fine iron dust out of the sample tube and had done a particularly good job of cleaning, whereas in the other test maybe we hadn't done that and a small amount remained in there.

The Court: Now, you have two columns for the iron there. Now I get the same sort of results. Or am I too far into what you are explaining? I get the same sort of thing away over in the last column for the iron in the sample taken out. I find the original one is large, which I take it you explain in the same way as you did the other, and then I find it increasing again down there. A. It increases because the inlet acid is increasing in iron concentration. You see, the iron from the tank—

The Court (interposing): But this is increasing. Let me see if I am right or not. A. The first one is 370, between the first composite in and the first composite out. The next one is 217, and the next one 410.

The Court: It goes up and goes down and goes up. Have you any theory at all about that? A. I don't know how to explain it. I haven't any theory for it.

Mr. Wiles: Were those samples the same size? A. Substantially the same size.

Mr. Lyon: Your Honor has referred to that before. I would like to give you some assistance on that. Isn't it true that same action is usually found in corrosion of a hydrochloric acid on steel—that it goes in waves? Have you made any tests of that kind? A. No, but the question was asked me yesterday why the amount of iron dissolved was low at the beginning of the test and then it rose up and fell off. The reason in that case—I just happened to think overnight—could possibly be the tank acid was 85° F, the tubing was 72 because it is in a thermostatically controlled building, and when the first acid went through the tubing it wasn't quite up to the temperature so the rate of corrosion was kind of low. When the tubing got up to 85, the rate got up high and the lead and metals in the acid are doing their inhibiting action by forming a minute film of molecules of this stuff, and then tend to drop down as you went along.

Mr. Lyon: That might be a possible explanation but I don't think the witness advances it as necessarily the one. I think it is only fair to state, Your Honor, there is no point about it in this lawsuit and the witness evidently hasn't studied it, but wherever you study corrosive action of hydrochloric acid on steel it seems, for some reason (that has nothing to do with this lawsuit) to go in waves. It starts at one figure and either increases or decreases, and then goes the opposite way and does it in waves, for some reason. It has nothing to do with this lawsuit. But it seems to puzzle Your Honor, so I thought I would make that explanation.

The Court: Another thing, as to columns 5 and 7 I

should keep this in mind, shouldn't I, that in column 5 we are dealing with a solution that has remained right in that transportation tank. To use the metaphor here that you want me to use, all the while, you first take out some; now the action is going on with the rest while it stays in there, and the last it has had more opportunity to work on it and therefore I would expect a little increase along there if there was any action at all. Now I come over here to column 7 and I have an entirely different proposition and I mustn't apply that thought to it at all because that acid is going on down through and I have nothing to account to me at all as to why the first that goes the whole length of that pipe should have any greater change on it than the next that flows the whole length of the pipe. They are quite different, so far as that is concerned, column 5 and 7, isn't that right? A. They aren't a great deal different.

The Court: I mean in the first one, if I am drawing cider out of a barrel that is getting hard, and I only draw it at different intervals, the last I draw out ought to be harder than the first. A. Yes.

The Court: Now, I haven't any such theory I can apply to column 7 at all. I find nothing in that because it didn't take any longer for one part of it to flow from the top to the bottom than it did the other, you see? A. But in flowing through this pipe it is picking up iron and the thing we are noting here is that apparently the rate of picking up iron does vary during this run.

The Court: Yes. But I say you can't explain that on the theory (it may be a poor theory) that the longer it stayed in there the better chance it had to get iron. While in column 7 it wasn't in contact with the iron any longer than the last batch with the first, while in column 5 the last batch was in contact with the iron longer. A. But there are peculiar things happening in this pipe that are beyond my ability to explain to you.

Mr. Owen: Well, I made some figures here, Your Honor, that seem to me to be entirely consistent with the increase in the amount of iron in the inlet samples. That

is where it is going in, the fifth column. I take the second figure there of 1200 and I find that the outlet, the corresponding outlet samples increased 370 grams of iron, and the difference between the next two is 417, and the difference between the final sets is 410, so it seems to me that increase in the outlet column is accounted for almost entirely by the increase in the iron in the inlet column.

Mr. Lyon: No. A. The difference is closer than the figures I estimated. I made some mistakes in substraction.

Mr. Owen: 370, 417 and 410.

Mr. Lyon: The court calls attention to the one above that and the fact there is a drop from the first one and then it starts going up and then it starts going down again. A. That has nothing to do with the test. That simply has to do with the cleanliness of the pipe at the start and the first gram or two of loose iron in this inlet. In the initial tank sample that first gram was taken directly out of the tank and therefore should be below the samples that were taken as existed in the tank, so 1106 should be lower than 1200.

Mr. Lyon: Why shouldn't there be the same difference at each one of these stages? A. It is, except the initial out.

Mr. Owen: And that has been explained several times.

Mr. Lyon: The first stage of comparison after that initial you say is 370, the next one is 417.

Mr. Owen: Yes.

Mr. Lyon: Why shouldn't they both be the same?

Mr. Owen: Your Honor, I think we ought to postpone the cross examination. We don't seem to be making any headway at all.

The Court: I agree with you.

Mr. Owen: Now, Doctor, this Table IX you say in column 2, "Menaul method acid and special tank." Will you explain what is the significance of the term Menaul method there? A. The Menaul method is as described in their patent, which involves the forming of a galvanic steel by electrically connecting the truck tank to the head of the well, or the tubing, and that method was employed here of electrically connecting the truck tank with the top of the tubing.

Mr. Owen: And that, I will state, is or was the defendant's practice, Your Honor, in the three wells from which samples were taken. They connected the truck tank to the oil well tubing by a copper cable, and their contents—

The Court (interposing): Any battery now mixed up with that?

Mr. Owen: No battery, no, except that this lead plate in the iron tank, and the acid as an electrolyte, in itself forms a galvanic cell. That is right, isn't it, Doctor? A. That is correct.

Mr. Owen: But there is no outside battery, no external electromotive force there.

The Court: Except as the tank itself, with the acid, forms it?

Mr. Owen: That is true. Now, explain your next table, Doctor, Table No. X, and at the outset explain the first statement "Menaul Method No Wire Connected." That means, does it not, that you duplicated the other test as closely as you could, but did not connect the wire in Table X test but you did connect it in Table IX. A. That is correct.

The Court: And IX and X you run just alike except for that, is that right? A. That is correct.

Mr. Owen: The purpose being to show, Your Honor, that there is nothing in this connection between the tank and the tubing.

The Court: I see. In this test, the acid was agitated for 6¼ hours in the tank. Series 1 tubing was used. The average analysis of the inlet acid was 158 parts per million of lead, and 3.25 parts per million of copper. That is considerably lower in lead than the sample before and somewhat lower in copper.

Mr. Lyon: About 25 per cent lower.

The Court: And agitated the same length of time and agitated in the same way? A. As closely as we could. And samples of acid from the steel tank were taken at 20 minute intervals, and the composite samples analyzed for iron. That is shown in the fifth column, the figures for iron

of inlet acid. In the seventh column are the figures for the exit acid from the tubing system, when the increase in iron content in acid due to the dissolving of iron from the tubing is figured, 330 grams of iron were dissolved by the acid. In other words, we got exactly the same results with or without the wire connected.

The Court: You have got intervening figures that are quite different, aren't they?

Mr. Lyon: And I call Your Honor's attention to the fact that there was only about half as much lead in the second sample as there was in the first, and 25 per cent less copper.

The Court: Less copper.

Mr. Lyon: Yes, 25 per cent less copper. A. I think it has been shown here that changing copper from 3 to 4 parts per million makes little difference.

The Court: But what I was wondering, how did you get so much less lead and one-fourth less copper if you took the same acid? A. Yes, the same original acid.

The Court: I am wondering and I was carrying the thought that there hadn't anything at all happened up to the point of starting that could be different. You took the same crock. A. That is true.

The Court: You took the same acid and everything. Why do we start away from scratch with such different figures? A. Agitating by hand is a very variable procedure, Your Honor.

Mr. Owen: Which run was made first, Table IX or Table X? A. The first Table IX was run first.

Q. Well, might not the larger amount of lead and copper in the Table IX run as compared with them in Table X run be accounted for by the fact that the first batch of acid you put in that tank ate off the lead from the walls of the tank? A. That is the explanation.

The Court: But I thought that was when it went into the tank? This is before it has had time to eat. A. It is after it has been six hours in the tank.

The Court: This is? A. That is the acid before it goes into the tubing.

The Court: This 352? A. 362.

The Court: You did have them just alike when they went in? A. No.

Mr. Owen: When they went in the steel tank, they were just alike.

The Court: That is what I mean. A. You have four runs that we made in this tank, a steel tank. It was polarized once, and the first run made in it, the lead was 362 after standing. The second run that was made in it the lead was given at Table XI, and it is 291, so it follows—

The Court: Which is the second now? A. The second run in chronological order is XI, which is 291, so it fell from 362 to 291. Then the third run is this one that we have here, and the fourth run is in Table XII, so—

Mr. Lyon: Were there any intervening runs? A. There were no intervening runs.

Mr. Lyon: These are the only runs you made? A. Yes.

The Court: Table XII is the fourth one? I will see if I get it in series at all. 362 and 291 and 168, is that it, and then 247? It jumped back up again. A. It jumped back up again.

The Court: I was wondering that would go down so I could have some theory? A. Taking a tank and agitating by hand is quite a variable thing, and it can vary 25 per cent, and that particularly applies to the lead concentration, and it is more difficult to dissolve in solution, just as we had trouble in dissolving lead chloride, and it depends on the agitation you get.

The Court: I don't know. I better follow that one. The first one was high because it was so—because it was the first, and there was more lead coated on? A. On the side of the tank.

The Court: Because my fourth one jumps way back up, which had from that standpoint the poorest chance of all. It was the furthest away from the battery plating of the wall, isn't that right? A. That is true. There is a considerable variation that you will get in lead content.

The Court: A witness when he performs his experi-

ment, he gets something he can't explain or I can't. I am glad to have you bring it to me just as you get it. Give me those in their order. A. 362, 291, 158, and 247, I believe.

Mr. Lyon: Now, Your Honor, I suggest you get the order of the copper contents too in the same arrangement, see how they vary. You have been looking at the lead. Why not look at the copper?

The Court: Well, all right. Give me those, Doctor. A. The first one is 4.3, then 2.88, 3.25 and 2.32.

Mr. Owen: Now, Doctor, will you explain, or had you finished with your explanation of Table X?

The Court: Go ahead. I will tell you all I haven't any theory, and I am waiting for you to give me one. A. Yes, I think I have completed Table X, in which we got substantially the same result as we had with the wire disconnected as we got with the wire connected.

The Court: When you got over to the final result they come out surprisingly close? A. That is right.

The Court: But they travel quite different roads to get there, as I see it? A. Yes.

Mr. Lyon: That is why I am objecting to these averages.

The Court: Well, all right.

Mr. Owen: Take up Table XI now, Doctor. A. In Table XI the run number is 2-M, and this again is the practicing of the Menaul process, with the wire connected between the tank and the oil well tubing system. The same temperature and rate of flow of acid was used.

Q. The same series of tubing? A. The acid was in the special tank for seven hours in this particular case, and series 2 tubing was used. The average analysis of the acid in the tank was 291 parts per million of lead and 2.88 parts per million of copper. In column 5, under samples taken at the inlet in parts per million of iron are given the iron concentrations of the acid in the steel tank at various times during the run. In column No. 7, under samples taken in the acid in parts per million of iron in the exit acid are

given the figures, the concentrations in parts per million of iron, and the acid leaving the tubing system at various times during the run. Calculating the increase in iron content in the exit acid over the inlet acid is 265½ grams of iron dissolved from the tubing.

Table XII, run 2-N is described. A Menaul method tank was used. The acid was placed in the tank for 6 hours and 30 minutes. The temperature was 85, the rate of flow was a gallon per minute, as before, but the wire was disconnected. Series 2 tubing was used. In other words, the same tubing as was used in 2-M, described in Table XI. The average analysis of the inlet acid was 247 parts per million of lead, 2.3 parts per million of copper.

The acid leaving the system,—the inlet acid in the storage tanks, in the steel Menaul tank was analyzed at various times during the run, and those figures are given in column 5, under samples taken at inlet, parts per million of iron. In column 7 are given the parts per million of iron in the exit acid leaving the tubing. From the increase in iron content of the acid and the volumes passed through, we calculated the amount of iron dissolved from the tubing, and it is 195.7 grams. In other words, it is somewhat less corrosive in this particular test with the wire disconnected than it was in the test 2-M where the wire was connected.

The Court: Do you attribute it to the disconnected wire? A. No, I attribute it to the possible variations in our test conditions. I don't believe it makes any difference whatsoever. I think the result should be the same.

The Court: There is a substantial difference though? A. 265 to 195 is 70 grams difference.

The Court: That is put in millions? A. That is grams of total iron dissolved, 265 grams of total iron dissolved. I don't believe the wire makes any difference, and that these tests would indicate that there was any appreciable difference. The first two comparative tests indicate the same result and the last two indicate the disconnecting of the wire gave somewhat lower corrosion. The main purpose of the test was to show that the wire doesn't materially change,—

decrease the rate of corrosion by connecting that wire, which is necessary to practice the Menaul patent.

The Court: There is a difference of 36, isn't there? A. Yes, a difference of about 70 grams of iron.

The Court: That is quite a difference. Isn't that a large amount? I don't know. A. When you take raw acid and run it through this tubing we dissolve 1000 grams of iron, and here we have a difference of 70 grams.

The Court: One would indicate 70 per cent less harm than the other, or 30 per cent less harm than the other. A. I would be willing to concede the disconnecting of the wire actually improved conditions. I would be willing to consider that.

Mr. Lyon: We are not talking about that. Tell him how much inhibition it decreased by disconnecting the wires, or per cent, as compared with the wire connected, in what per cent have you reduced corrosion, on your own figures? A. We have reduced the inhibition of the acid by disconnecting the wire.

Mr. Lyon: By how much per cent? A. By 7 per cent, approximately.

The Court: More than that?

Mr. Lyon: Sure it is more than that.

The Court: You have 265—

(Witness interposing): No, I stated it in the opposite from the way you stated. I stated the reduction in corrosiveness or the inhibition in coming from 1000 grams down to 265, there is 750 grams of iron difference; if we reduce it to 195 there is only another 70.

The Court: You reduced it more than before.

Mr. Lyon: That is right. A. In corrosiveness. I said inhibition—

The Court (interposing): But say you have reduced the corrosion more than 25% by this. You don't claim it did, I don't claim it did.

Mr. Wiles: When you have it pretty well inhibited, for instance a 99% inhibition, and raise it to 99½, it is true there is a difference 50% in corrosion but practically you have no corrosion in either case.

The Court: All right. But you have reduced the amount of corrosion by more than 25%.

Mr. Wiles: That is true, but you have started out by reducing it down to a very small amount in the beginning.

The Court: Sure.

Mr. Owen: Your Honor, in considering this particular question you should go back to the tests made from the stoneware crock with uninhibited commercial acid. Those showed in Table I a total grams increase in iron of 1043.

The Court: I follow you that you say neither one of these are corrosive enough to do any harm. That must be the contention.

Mr. Wiles: They are very greatly improved in that respect.

Mr. Owen: They will do some harm, they are not perfect.

The Court: Then when it was disconnected it did change it more than 25%?

Mr. Owen: I don't know whether the doctor has any theory as to why there was less corrosion with the wire disconnected than there was with it.

Q. If you have a theory, I would like to hear it. A. The theory of electrolytic protection by galvanic action is interesting from a theoretical standpoint of connecting a metal which will dissolve more readily than iron to the iron and many people have tried to apply that in actual cases and have found that instead of getting inhibition they get the reverse. They get more corrosion when they connect things together like that, and particularly if they try to impress potentials upon a metal. I don't know whether this would be an instance of that case or not. As far as I am concerned, I would be willing to say both on the results of these tests and from my theoretical knowledge, that this connecting or disconnecting the wire would have absolutely no difference—it would be a small amount on the inhibition.

The Court: I get this from what you say. You performed many experiments before you reached the conclusion this connection of the wire was the cause of the

change? A. Yes, I wouldn't expect it to be of very great difference one way than the other.

The Court: I say you performed a good many experiments before you reached a conclusion. A. The results of these tests indicate to me substantially there is no inhibition produced by that wire connection.

The Court: Of course that is the danger. I agree fully with the explanation that that was less destructive—the acid was to iron, when it was disconnected than it was before; I wouldn't want to reach that on just one experiment. And I understand you clearly to say you don't reach that conclusion on one experiment. A. No, these experiments should be considered with the tests that I ran before. In describing those tests I mentioned that the first two tests I duplicated the composition of the acid in the steel tank and ran it directly from the stoneware crock to the tubing system; not only disconnecting the wire, not even having the lead plate in there in those tests we got exactly the same results with the wire connected or disconnected. In other words, six different series of tests, all duplicating, all pointing to the fact that the lead plate, the wire, the tank, has no effect on inhibiting corrosion in an oil well, and that also agrees with all theoretical principles of electro-chemistry.

Mr. Owen: Doctor, while we are on this subject, I would like to have your theory of the Menaul proposition that the pipe can be protected from corrosion by connecting up the tank to the pipe by this cable. A. The theory, as I explained it, in agreement with these tests, as to why the tubing is protected when they practice the Menaul patent is simply due to these metals which are added in the acid and which are fed the acid containing those metals, fed into the tubing. That accounts completely for the inhibition. The placing of a lead plate in a steel tank at a position electrically remote from the bottom of the well, or even inside the tubing, from a consideration of electrical circuits is that you might get some little inhibition on the end of the pipe that is sticking into the tank, but in any

circuit the electrical current takes the easiest path that it can to go through the circuit. It doesn't go through all the way to the bottom of a 2000 foot well, jump to the pipe and run back. If you have an electrical circuit and have two resistances connected between two bus bars, one resistance has a very high resistance, the other very low; all the current goes through practically the low resistance. There is no reason as to why the current should go down the acid through the tubing, to the bottom, jump across the tubing, back through the tubing, back to the tank as described in defendant's patent, and in that way protect the tubing.

Q. I wish you would trace that circuit as described in the Menaul patent down into the well and then back to the tank. A. They do describe in the patent one method of operation which would have some remote change of working, but which is so impractical that I don't believe it was ever even tried out, and that is to lower a lead wire down to the bottom of the well, keeping it from touching the sides of the tubing, and pouring acid down between the lead wire and the tubing. Under those conditions, you might get a little bit of inhibiting effect. But with the lead plate back in the tank and the circuit that you have to follow—if I may draw on the board here, I would like to draw it.

We simply draw a vertical tube in the ground, that you can visualize as being a couple of inches in diameter and several thousand feet in length, and that tube is full of acid. Then we connect that into a truck tank, and here is the truck tank, in some shape or other. In the bottom of this tank is this lead sheet and more or less lead covering the sides. The iron is partly exposed. There is definitely a tendency, a potential, which would make the lead negative as compared to the iron tubing, and a galvanic cell which you might figure would take some lead and plate it upon the iron. Now, between the tank and the head of the tubing there is a copper wire connected. Steel to steel, the tubing and tank. We have a circuit.

The Court: Each filled with hydrochloric acid. A. That is true. This is all acid. Now, we have a cell in which

this is one electrode, the electrolyte or solution in the cell between the electrodes is hydrochloric acid, and this whole system is another electrode. The whole system is one electrode. Now, the passage of current between two electrodes in a cell, the current goes in the most direct manner it can. Now, the actual voltage of this cell, as will be shown possibly by the defendant, or we may bring it out, is on the order of a few hundredths of a volt.

Mr. Owen: I may read from some of the defendant's literature where they stated the voltage of the battery formed between the electrodes is ".35 of a volt. Therefore it should be a good conductor and as little resistance as possible in the short circuit so that this low voltage current can readily flow from one point to the other."

The Court: Now, this copper wire across there just hitches two irons together. A. Two metal plates together, and in between you have acid.

The Court: How is it any different than as though here you had a tank over there, and the pipe coming right immediately connecting to it? In other words, are all of you—I don't know, maybe—are any of you claiming that that makes it different than as though this was steel across the top and that just fitted right to it and came right around and it was all steel and all filled with acid around here? Does the fact that that is an open space there and this has copper across, does that make it different? A. It makes some little difference, but not appreciable. It is the same as you have in any type of battery where you have one electrode, like a carbon rod in an ordinary dry cell, that is the one electrode in the cell, that is the solid conductor, and then the other electrode in the dry cell is zinc. In between you have a thick solution of ammonium chloride. That is a typical battery. And you don't get that battery to function unless you connect it electrically outside. In other words, the dry cell just stays without acting until you touch a wire across here, or put a flash-light bulb across here, and then the current flows and then these actions take place. You have a complete circuit here with electrical current flow-

ing through the cell. And the light lights up. Now, the same thing is true here. If we have that disconnected, and the other connection, if we had this welded across here, we would have the same sort of condition.

The Court: That is what I thought. A. And the passage of current between.

The Court: Here you had your typical one, and you point out to me that you have one zinc and the other— A. (interposing): Carbon. One zinc in the dry cell.

The Court: Carbon and zinc here. A. Where we have this.

The Court: Lead is plating on one of them. A. Yes.

The Court: And to the other. A. The iron of the pipe, the tubing, is the other, all the way down the well. Now, the current flowing between these two electrodes passes through the path that has the least electrical resistance; it takes the easiest path out. It has to go through the acid, and, therefore, it has to go through the acid to the pipe, from the pipe back through the electrical wire and back around in this sort of a circuit, but if here the current went around in this direction and completed the circuit with this outside wire, we have a complete circuit.

The Court: You haven't got that hitting the lead at all. You have got to have that current go to the lead. A. I assume this was coated with lead. So the current comes from here, to here, back through the wire and back to here. There is absolutely no reason why it should take a path and run through the column containing solution for three thousand feet of a very low, poor conducting solution, three thousand feet, jump to the side of the tubing down here, and then run back throught this pipe.

Mr. Lyon: Well, just assume that the entire side of the tank is coated with lead, and go ahead with your proposition. A. The inside of the tank?

Mr. Lyon: You can't have current flowing from lead to lead. A. You have exactly the same condition.

Mr. Lyon: You can't have current flowing from lead to lead. The current will flow to the nearest iron. A. If

this tank is completely coated with lead, as you state, and as I believe is your contention here—

Mr. Lyon (interposing): Yes. A. Substantially so.

Mr. Lyon: It is completely covered. A. It is completely covered. There is no iron exposed in the tank.

Mr. Lyon: You can't flow the current from the lead plate to the lead covered wall. A. There is subsantially no current flowing from the lead plate to the lead covered wall.

Mr. Lyon: The current will try to flow from the lead plate to the nearest uncovered iron. A. I have exactly said that. It would flow from the lead across here. I consider this whole tank a piece of lead, because this is substantially coated with lead. That is all lead. Now, the current flows from this lead inside the tank to this tubing. But it flows through the shortest path of acid it can flow through, because it doesn't want to go through a long path of acid.

The Court: That sounds reasonable. A. Therefore, it doesn't go down to the bottom.

The Court: As I understand it, he is asking you to assume that that is all coated. A. That is all lead.

The Court: All right. Where will it go to? A. It goes from the inside of this tank, any place from the lead on the inside—

The Court: That is all lead. A. That is all lead.

The Court: Now, where? A. It goes to the end of the tubing.

Mr. Lyon: When that gets covered with lead, what happens?

The Court: That is what they (defendant) will claim, I suppose. They haven't said that, but I take it the theory is—and I want you to knock it out if it ought to be—I take it their theory is that that will go to the end of the tubing and it will coat that, and then it will go to the next nearest and then the next and the next.

Mr. Lyon: That is right. Theoretically, that is the basis of the engineers' reports on this.

The Court: And I think—they don't claim that it

would, while that is all open, run the whole length of the gamut and coat it all through.

Mr. Lyon (interposing): No. A. It would have to eventually run the whole length of it and do that plating at some time, by their contention. It is not possible to take a metal, a pure metal, suppose we take pure lead, and put it into a solution—let's take hydrochloric acid—and not take any other kind of an electrode over here, it is not possible for that lead to dissolve itself and then also to plate itself out in a continuous sheet on the other electrode without adding some voltage externally, no more than you can lift yourself by your boot-straps. The energy that this lead gives off in dissolving is required, and an even greater amount of current is required to plate lead from this pole onto this other electrode. It hasn't enough kick to plate a complete film of lead on this surface. So there is possibly a molecule here and there, scattered around. There is some very slight amount of plating, but you get that same kind of plating when you immerse iron in a solution of a lead salt.

The Court: The thing you are meeting—you don't have to meet the claim that it would start some plating down at the end immediately, down at the bottom immediately when you started, as I understand, because that isn't what they claim. But they do claim, and what you are meeting, is that it would not have enough energy left to even plate the tank, so it would never get through plating the tank? A. That is why they put the battery in, to get the plating on the tank.

The Court: And you claim they don't get sufficient—am I stating your theory and contention correctly about this, that it never does get far enough along so that it even gets the tank, out of which it is flowing, plated, and therefore it never begins to plate the pipe? A. It partially—this voltage or potential energy the lead has contained in dissolving is used and there is a slight tendency to plate out lead on this coating, but the amount of lead plated out is an atom here and an atom there, and very imperfectly cov-

ering it. In order to get a complete covering, they want to use a six volt battery, and you must remember we are talking about voltages on the order of a few hundredths of a volt here. And when they want a complete coating to protect their tank, they connect it to a six volt battery to help out the lead solution. If you take an ordinary lead solution, or a lead salt, and immerse iron in that, some of the lead will deposit on the iron. A very minute amount. If you put a few hundredths of a volt on, you get maybe a few more atoms of lead on. But to get a complete sheet of lead plating on a surface, you have to place some external voltage on it to do that.

The Court: It is my understanding that you say that in this weak battery it will never, the lead will never so completely cover the steel walls of the tank, and the little end of the tubing that stands down into it, so that there will ever be any current passing on the well side of the point where the copper wire is connected to the tubing? And it will always turn towards the tank side of it and go round and round in that side and that it will never, the tubing, get coated down beyond with lead, beyond the connection to the copper wire in such a way that the current will turn towards the well, and so down the tubing and then come back through the solution? A. The amount of any current that flows down here is substantially negligible. We have actual measurements of the current that flowed through this wire in our test, and it is in the order of millionths of an ampere that flowed, even here, and to express how much it plated down.

Mr. Lyon: What order of current density is required to plate lead on steel, what order of current density? It is in the order of a millionth of an ampere, isn't it? A. Current density has nothing to do with it.

Mr. Lyon: You made a measurement of this current and it is only a millionth of an ampere. That is all the current that is required to plate lead on steel, isn't it? A. There is quite a bit of information in the literature on the electrolytic protection of pipe lines, and this is an electrolytic protection.

Mr. Lyon: Can you answer that question? A. I don't have any information. I am telling you for electrolytic protection practiced commercially on pipe lines the current required is tremendously greater than a millionth of an ampere.

Mr. Lyon: Do you know whether or not current in a millionth of an ampere is sufficient to plate lead on steel? A. I can't tell you that, because the quantity of electricity flowing determines the amount of deposition of hydrogen and lead, which are two things that are simultaneously deposited and the conditions that you would have would vary greatly, and I don't think it would be possible to measure it, unless you measured a tremendous number of tests, and it is so far below any commercial figures given for electrolytic protection. Then it violates the deposition of electrical circuits, and also the tests that I have run here quite definitely prove that its electrolytic protection is absolutely of no value.

Mr. Lyon: I am trying to get you to tell us whether in accordance with your theory that there was no appreciable continuous plating in the defendant's tanks due to the presence of that bonded lead plate, if it would make any difference in the life of the tank whether or not the bond between the lead plate and steel wall was broken? A. I have said that you get some electrolytic protection in that tank, I believe. I have no tests to indicate otherwise, but I believe, and it is entirely reasonable that you would get some protection, that this lead would definitely have a potential which would tend to put molecules around on the surface and exert some little protection. Just how much I can't tell you, but to get thorough protection apparently you have to go to very high voltage, an added voltage, which will coat the surface over, practically continuously with lead.

The Court: I understand you, Doctor, to say that whatever the conclusion may be about protection given to that tank, if I go in there 5000 feet there is absolutely no electric current resulting from that lead? A. That is my contention.

The Court: Now, then, I have got the idea that you say that for practical purposes there isn't any of the other side, copper wire connection on the well side that the current starts from, where the copper wire connects to the tubing, and makes its way back through the solution on the tank side? A. The positive flow of the current is in the direction through the walls of the steel tank, through the lead coating on the inside, across the acid and it comes to the closest point on this metal tubing that it can, the current passes through there, and then back around in that direction, any current.

The Court: It never goes any further towards the well than where the copper wire connects with the tube?

Mr. Lyon: I would like to correct that. In your explanation it wouldn't make any difference where the copper wire from the tank was attached to the pipe. That hasn't anything to do with it? A. That has very little effect.

The Court: But you haven't any of you gotten what is bothering me. I understand the doctor to say that wherever you attach it, and I agree it doesn't make any difference, but that when it comes in contact with that tubing that it never goes any further towards the hole in the well, but its course leads back now into the tank? A. That is the main circuit, and the amount of current that would flow—there would be very little current that would flow, very little.

The Court: Now, how far, that is what I am getting at? A. It wouldn't flow, in my opinion, any distance at all, and the amount is so negligible—

The Court: In feet how far? A. I couldn't tell you. You can't calculate it.

The Court: You know it wouldn't be 5000 feet?

Mr. Lyon: You don't know that. A. It is my opinion it wouldn't go twenty feet.

The Court: Well, now, that is what I wanted to get at. A. That is my opinion. I can't prove it, but that is my opinion.

The Court: You could pull one of these things out some day more than twenty feet.

Mr. Lyon: He said that was his opinion and he couldn't prove it.

The Court: I know it. Maybe you can disprove it.

Mr. Lyon: I am not claiming I can. A. We haven't any proofs on that, I mean in the small set-up we made with our tubing system connecting the wire, we found where the tube,—where the wire was connected was inhibited. We had 112 feet in this tube system that we have and we measured the loss in weight of each length of tubing, and even the length where the copper wire was connected wasn't inhibited, so I say the amount of current that flows is not enough to do any good. The fact you can break this steel completely and take this whole thing away and get exactly the same amount of iron dissolved all is evidence.

The Court: It is my understanding of your testimony that the underlying reason for that is that it is your belief and opinion that this iron in the tank, not to exceed twenty feet of the end of the tube, never gets enough coated with lead, so by what it has all got, it has got enough iron to satisfy its appetite right there? A. That is right.

The Court: Isn't that the meat of it all? A. That is right.

The Court: And their contention, evidently, from this, because I feel so right about it, is the fact you wouldn't start at the bottom of the well, if there wasn't any necessity for it,—you don't take a great big detour unless the road is bad straight ahead, but their contention, as I understand it, is that they have got a tank that is coated so much it doesn't satisfy its hunger for that, and begins at the end of the tubing and rapidly goes down coating the tubing and in that way protects it.

Mr. Lyon: May I state the proposition? Our proposition is that we use this Menaul method to protect our tanks.

The Court: Yes.

Mr. Lyon: Our theory considers there is a good possibility that it may do some protecting of the pipe, but it is

purely theoretical whether it does or not, and there is no way in the world of establishing it one way or the other.

The Court: As long as they claim their purpose is to coat their tank, that is what they say, that is, that is what they say their purpose is, and it does give protection to it?

Mr. Lyon: We will prove that.

The Court: I will ask the witness right now, what do you think about that? A. Does it give protection to the tank?

The Court: Yes. A. It gives a slight amount.

Mr. Lyon: You don't know if it is more than that? A. I don't know. We have run tests in the laboratory against steel and it might inhibit the corrosion 30 to 50%, or something like that. It would vary with the conditions. Then you plated this battery to get more lead on this and that—

The Court (interposing): I haven't a very big dispute about this thing.

Mr. Wiles: The tank hasn't anything to do with the lawsuit any way.

Mr. Lyon: I think it has this much to do, Your Honor. Somebody said our use of this method was a smart trick in order to do something down the well.

Mr. Wiles: I say it is.

Mr. Lyon: That isn't the purpose of it at all. It is to protect the tank.

Mr. Owen: I would like to have the witness retrace that circuit in the defendant's tank when it is connected up with the oil well tubing by the copper cable. In tracing the circuit, Doctor, although you are illustrating it on the blackboard, please make your description perfectly clear so that when read from the record it will be understandable? A. The tubing which may be simply dipped into the tank, or which may be connected through some pumping arrangement at the bottom of the tank, is electrically connected by means of a cable at the side of the truck tank; and, therefore, we will show here a copper cable connecting the oil well tubing to the outside of the steel tank.

Now, this steel truck tank has on its bottom a thick

sheet of lead, which is connected to the tank, and then due to their preparation of the tank by their so-called polarizing method, they put on a thin coating of lead on the side of the tank, and so we have a steel tank with the bottom practically covered with a heavy sheet of lead, and the inside of the walls of the tank partially covered with electroplated lead.

In the tank we have our hydrochloric acid for the acid treatment. Now, we will assume that this tube is full of the fifteen per cent hydrochloric acid, which it would be in case we were transferring it, possibly, through a pump or some other means from the tank down into the well.

The Court: Now, I am thinking of that, and see if I am wrong, I am thinking of this as one continuous body of hydrochloric acid. A. That is correct.

The Court: I am thinking of the steel as one continuous body of steel, and I am ignoring the copper wire. That is simply a little bit better conductor stuck in there, and I am thinking of this as this odd shaped thing running down there and all of that, but I am thinking of this as a solid bit of steel with all that connected across there, of course. A. That is right.

The Court: Just as if the steel ran across. And one big spot of lead down here in this, and the sparsely settled lead sticking up there. A. That is correct.

The Court: That is the idea I am carrying about that outfit. A. That is exactly correct. And if you imagine that down this well you are about one to three or five thousand feet away from this lead plate, so that this end of the steel tube in this example would be several thousand feet away from here. Now, the operation of this cell is that the lead goes into solution and current passes from the lead into the solution. Tries to get to the iron. It will go to the iron that is closest to it.

The Court: I would think so. A. In other words, the current from this lead would go to this iron. In order to protect down below here, the current has to pass from this lead sheet, up through the pipe, through the acid, always in

the acid, down through this column of acid, then come to the wall of the pipe and to its protection and then back through the wall of the pipe, back through the copper wire, back into the tank, to the lead plate.

The Court: Yes. A. In other words, in this example, which is a simplified diagram, the current goes from the lead into the solution and then travels in varying amounts to the iron surface closest to it, or to the iron surface three or four thousand feet away from it.

My contention is that the amount of current that passes from this lead electrode or sheet to a point a thousand feet away is substantially zero, since we have measured the amount of current that passes between this whole tubing system, the entire tubing system and the tank which we had in the laboratory, and the amount of current was on the order of a few millionths of an ampere, particularly in that the resistance of this hydrochloric acid is considerably greater than the resistance of the metals, and therefore there is absolutely no reason why current will take the hardest way to go any place. That is simply a law of nature. It would take a long while, and a fairly appreciable amount of current at least something greater than the order of a few millionths of an ampere to cover a thousand square feet of surface with any protective coating into the well.

As a result of the tests which we have run, when we broke that circuit, which prevents that action, when we broke that we got a little better action than we had with the wire in there.

And as I told you before in this applied electrolytic protection, there are just as many examples where electrolytics work in a negative manner than in protecting the metallic surfaces, and therefore the statement that I would make from our tests is that the wire had little effect, the electrolytic protection had little effect one way or the other, and I think that is what I stated last Saturday. And then the other argument, the difference in potential that existed between this tank and the tube in our set-up was down in the order of one or two hundredths of a volt. The difference

between this lead plating side of the tank is a little greater than that, I will admit, but the potential difference is so slight that any protective action that you would get, the tendency to plate lead out is negligible, because that plating out requires a different potential. In the surface of ordinary steel pipe differences in potential occur between different parts of the pipe. That is, if you take a piece of pipe and expose it to hydrochloric acid, or any water solution, differences in potential between particles of the steel and the iron crystals of the ferrite amount to as much as several tenths of a volt.

In other words, down at the bottom here we have little cells where a particle of iron carbide and a crystal of iron in close contact have potentials of one to three-tenths of a volt, and those little cells will have much greater voltage than you have impressed on this whole system, and therefore the surface of the iron pipe has a small galvanic cell, and those small galvanic cells,—take your inhibitor, which is plating solution in copper, and plate out the metal without any external action. They will plate out a small amount of lead and copper. That is the way the lead and copper acts as inhibitor. It doesn't need this outside current.

It has several tenths of a volt out in the open. A piece of pipe in the open with hydrochloric acid, or any water solution, on that surface there are differences of potential several tenths of a volt. We have that potential and we put a solution with a little bit of lead and copper in it. The current in that little galvanic cell causes the electrical chemical cell action and plates the lead on one of those electrodes.

Now, if we impress another one hundredths of a volt of copper from some source outside, say three thousand feet away, and with a resistance between it, we are not going to get any greater effect or any protection on this metal in solution, and therefore the metal in solution combined with the differences in potential that exists in the steel itself, the lead plates out to some degree, the copper plates out quite thoroughly, and you get a protective film formed on the

surface of the iron just by immersion of the steel in this lead and copper containing solution.

The Court: Well, lead chloride and copper chloride, do they have the possibilities for the little electric current just the same as the free copper? A. They are somewhat different in that you plate on a perfect film of lead, it doesn't act quite the same way as a sheet of lead. That is 100% lead, and you get a definite voltage or the tendency for that lead to dissolve but if you just partially cover it with a few atoms, you don't get quite as high voltage.

The Court: Is this plate we talk about of lead free lead just like our lead plate is when we start or is that coating like the particles that are floating through the acid and really lead chloride? A. It is metallic lead. It is small particles of metallic lead, and it isn't lead chloride.

The Court: Well, now as it is, on its way across that, of course, has its origin in the lead plate and it winds up as a thin coating some place at a little or great distance. On its way over there is it free lead or lead chloride? A. It is a lead ion with a valance of two and an atom of lead with two electrons removed from it. Completely different.

The Court: It is hooked up— A. With chloride.

The Court: That is on its way over it goes to pieces again? A. It is plated out. If you will let me, I will show you how lead chloride solution and copper chloride solution—

The Court (interposing): I want to see after it leaves as free lead and winds up as free lead, as I understand it, it gets a ride across there with some new neighbors. A. Yes.

The Court: Whether it comes out in a parachute or what, I don't know, but after it takes that trip across it gets out as free lead again. A. Well, now, the first thing I want to explain is what happens when you take a piece of ordinary steel and immerse it into hydrochloric acid which contains lead chloride and some copper chloride. We will assume the lead is the material that is going to do the inhibiting. We have shown in various tests it does a little. I will explain how it does it. There is no free lead in this

system whatsoever—it is just taking a piece of metal, steel, immersing it into a solution of hydrochloric acid that contains the lead chloride in solution. I haven't taken up the lead chloride.

The Court: You have just got lead chloride then? A. We have just lead chloride without any lead sheet at all (indicating). If we consider a piece of steel, in the structure of steel there are crystals of various materials present in the steel that crystallize out, and some of those crystals, the major part of them, are crystallizing pure iron or ferride (indicating on the board). Now, let us assume that we have some ferride crystals here, covering most of the surface, but in steel we have other elements than iron; we have carbon; we have sulphur and phosphorus, and those elements combine with iron to form compounds, and those compounds, when the steel solidifies, they crystallize out and form small particles and crystallize around through the surface.

The Court: Some of them are better for some uses, for certain uses, and some worse for certain uses. A. That is correct. So we will consider that these are iron crystals, and let us consider here—I want to draw it large enough so that you can see it—this is a particle of Fe_3C, or cementite, which is the common form in which carbon occurs in steel. So we have here a particle of cementite in the surface of steel.

The Court : I am to think of those as separate molecules? A. They are not separate molecules. They are separate crystals. You can see them under the microscope. They aren't down to the molecules. They are large enough to be seen under the microscope.

The Court: But made up of many molecules? A. Made up of many molecules.

The Court: They are not all alike? A. They are not all alike. In the case of the Fe_3C, there is different, very small crystals of Fe_3C, and the ferrite is considerably larger in size. The ferrite crystals, being in larger amount, why, they crystallize and tend to form larger crystals. The amount of iron carbide is usually less than 1 per cent, and,

therefore, there is such a small amount coming out the crystals are usually finer, and this particular arrangement, the iron crystal in electrical contact in the body of the steel with another material, Fe_3C, two different materials in electrical contact, that is, two crystals which are touching each other electrically in the piece of steel—we are looking through a cross-section of the piece of steel—outside here, if we put on the surface some water solution, and let's put hydrochloric acid, in the solution, this is what occurs. First the iron has a definite potential or tendency to go into solution, which we call its solution tension. It has a very strong tendency to go into solution. The iron carbide very little. We usually measure those differences in tendency to dissolve by the voltage, which is the electrical pressure tending to go into solution. This iron has a very great tendency to go into solution. This material has substantially none, practically zero. It is quite inert.

The iron is a material that tends to dissolve. Now, here we have, if we measure the voltage between the iron and iron carbide, we find it is in the order of one to three-tenths of a volt, which is a fair voltage. The difference in potential right in two adjacent crystals here, we have a water solution on top in contact with these two dissimilar particles.

The Court: I thought we had hydrochloric acid. A. That is a water solution, hydrochloric. We have three-tenths of a volt difference. This force is there tending to throw the iron out into solution.

The Court: Yes. A. That is the driving force for this cell. And we have a complete electro-chemical cell, we have a cell with an electrolyte, two different electrodes at different potentials, and we have the external circuit with the solution, the metallic circuit closed, just as though we had this electrode here or here.

The Court: For all we thought of that as a piece of steel, that we put in, you get that going on within the family. A. It is right inside the body of steel. It is just as though we had a piece of iron here in a galvanic cell, like

a dry cell, and a piece of iron carbide here, and we have .3 volts difference between the two, and then we took and put a bar of steel or something across outside here and dip this in hydrochloric acid. It is exactly the same action.

The Court: In other words, it is the same as if there were two different metals. A. Two different electrodes.

The Court: Like what goes on between copper and iron, or zinc and copper, or lead and iron. A. Yes.

The Court: So as between this kind of iron and this kind of iron, you get a— A. (interposing): That is correct. They are the same action entirely.

The Court: I follow you. A. All right. Now, if we can get this picture—

The Court (interposing): How does that compare with between lead and iron? I mean in strength? A. Well, the lead and iron that we got between this tubing and the tank was on the order of one to two hundredths of a volt, and here we have three-tenths right in the metal itself, in point to point contact with the metal. In other words, the point I want to make is to impress one or two hundredths of a volt on a three or four thousand foot pipe line, you can't do it and hope to do much protecting of this end, while in the iron itself there are differences of potential amounting to a tenth of a volt or more. This iron has this force which is tending to throw iron into solution. And when you take an atom of iron and throw it into solution, iron will not dissolve in water solutions, but it will form a ferrous ion, and the ferrous ions will stay in solution if you have got a negative ion associated with it, and when you do that you produce two negative charges or electrons. And so this force throws an iron ion into solution. The cell is going to act now. The action of the cell is throwing an iron ion into solution. The two electrons go through this circuit. The concentration of electrons in this electrode now is high and the electrons flow through the circuit.

The flow of electricity through a metal conductor is a flow of electrons. It is not a flow of actual particles, like iron atoms. That only takes place in water solutions, where

they can move. But in an electric, solid electric conductor, why, it is an electron flow.

The Court: One of them joggling the other. A. Yes. And this electron pressure on this side is considerable. It is three-tenths of a volt difference in electron pressure. Those electrons come over and try to charge this electrode up to the same potentials that they have, which is three-tenths of a volt.

Now, in the solution we have hydrogen ions and chlorine ions, and we have a considerable number of them. And in the solution these ions are moving. We have a passage of current through the external circuit and we are going to have a flow of negatively charged ions in this direction and positively charged ions in that direction. The passage of current through an electrolytic conductor causes a motion of positively charged ions in one direction and a negatively charged in the opposite.

These iron ions go into solution. Then two chlorine ions, which are associated with the hydrochloric acid, two of those come over and simply—they don't hook up solidly with them, but they are in a loose sort of kinetic state of equilibrium with the chlorine ions and iron ion. That is ferrous chloride in solution. That is ionized ferrous ions and chlorine ions.

These two hydrogen ions, which are going in the direction of flow of the positive electricity come here and plate out hydrogen on this electrode, and so we have a film of hydrogen produced on this electrode, and the electrode is converted, now, from an iron, iron carbide electrode, you see, these hydrogens come here, deposit, because the electrons, the two electrons we got off the iron atom came over to this here, and the two electrons add onto the two hydrogen ions, and we have hydrogen deposited. Now we have a hydrogen electrode and an iron electrode.

The Court: What are the hydrogens doing on that iron over there? A. The hydrogen changes this from an iron carbide electrode to a hydrogen electrode. It has a different potential now. The iron carbide had practically no potential, but the hydrogen has some potential.

The Court: Is that detrimental. A. That is detrimental only to this degree—

The Court: Does it affect that iron, now? A. It is not detrimental, but whenever this action occurs that I have described of iron going into solution from the metallic state to the ionic state, you have the corrosion, you have converted some of the steel. Just the hydrogen plates out over there.

The Court: Isn't that protection? A. That is a protection, because the voltage of the cell now drops from about three-tenths of a volt to about one-tenth of a volt.

The Court: That is what I was thinking. It would tend to immunize that. A. Polarize it.

The Court: Cure itself of this danger. A. Yes, it does. It does tend to do that. But in this particular solution it is not sufficient, the hydrogen will not build up a sufficient back voltage or tendency to go into solution to repress the flow of current in this cell to stop corrosion. The corrosion will continue. If you put a piece of steel in hydrochloric acid you will get bubbles evolved, and the action continues and it continues in this particular manner.

The Court: I would think it would be in a receding, a decreasing degree? A. No. On this particular surface, the hydrogen plates out, and then when it gets a thick enough film, bubbles form, and the bubbles escape and uncover the surface of the iron carbide again, and so the action continues.

The Court: There isn't anything there for the hydrogen to hook up with at all? A. No, it is simply hydrogen gas. It has been converted from the ionic state in solution over to hydrogen gas, such as they use for filling balloons, and so forth; and that gas forms a thin film on the surface and then bubbles away. But the voltage of the steel is dropped somewhat from three-tenths maybe down to one or two-tenths of a volt, due to this hydrogen. Hydrogen puts resistance in steel, and that resistance tends to reduce the amount of current that is flowing in the circuit. Now, we are going to put some lead chloride in the solution, and

when we do that the concentration of lead chloride is very low, I mean—

The Court: Do they add that pure iron, every particle of it—if you added all that in, the hydrochloric would not act on it? A. That is substantially true. If you could get a piece of pure iron that had every crystal and every particle of it in exactly the same state, so that there would be no difference in potential—but that is a practical impossibility—they have tried to make pure iron, and they find that the difference in the annealing of one part to another creates a difference in potential. In other words, if you have pure iron with no impurities, if you strike a piece of pure iron with a hammer, the voltage or potential of that struck part is greater than the annealed or—greater than the annealed part that has not been struck at all; and, therefore, you create a potential in C. P. iron, and it is impossible to create a formula without some differences in potential, either due to differences in annealing, due to differences in composition, or the working of the metal, and so you get this difference in potential which starts with this galvanic action.

Well, now, if we put into here some lead salt, like lead chloride, the chloride ions that we would have migrate toward the iron, just as the chloride that was associated in the hydrochloric acid. The lead ions would come over in the direction of flow of the positive ions and try to discharge along with this hydrogen.

The lead ion concentration is so small we get a partial coating out of lead on this surface, and so we get there with the hydrogen and we get a few spots of lead plating out, but that lead has a very important effect upon the action of the cell, although it is present in small amounts. That lead holds the hydrogen film on the surface. It holds the film on the surface to a greater degree than if the lead were not present. The copper does the same thing.

The Court: The lead does not then, if I can use my magnifying glass, it doesn't actually hit the iron and coat the iron, but as I understand it, there is a sandwich and

hydrogen is next to it? The hydrogen is next to the iron? A. Here is a particle of lead plated out, and here is another one, and so on, maybe a molecule or two, quite an imperfect coating. Then the hydrogen fills in like this, and those little points hold the hydrogen film on to the surface. Your solution is out here.

The Court: I thought the hydrogen was there before the lead got there? A. No, in this case—

The Court: Over here I didn't have any lead? A. You didn't have any lead in the first case.

The Court: But we had a coating of hydrogen? A. Yes. When you have lead present, they both start coming out together and you get an imperfect plating. There are a number of metals that have that particular action.

The Court: As I understand it, the lead chloride is out in solution? A. It is in solution in the acid.

The Court: And these particles of iron start from a point and find their way around and pick the iron up on a little bit of a coastal trip around to the different kind of iron? A. Yes.

The Court: And in that course they pick up the lead chlorine? A. The chlorine from the lead chloride and the chlorine from the hydrochloric acid. You have ions from both. You have both ions.

The Court: I don't understand everything, chloride and chlorine? A. Chlorine is the element, chlorine. That is the greenish gas. Chlorine is the element and it is not chloride. Chloride ion, Cl is an atom of chlorine.

The Court: Chloride is hitched with any other metal. A. A negative electrode, and to get chloride, the chlorine particle, if we take a chlorine atom, it is electrically neutral. A chlorine atom is electrically neutral, and if we hook two of them together we get the chlorine molecule, which is ordinary chlorine gas that is used for treating water and sterilizing and so forth. But if we hook this chlorine up with a metal then we form chloride, and that ion is different than the chlorine here because it is electrically charged, and the chloride can exist in solution in very high concentration.

You can't take chlorine gas and put it in water. It won't dissolve. If you electrolyze it it won't migrate because it is not electrically charged, whereas the chloride ion is electrically charged.

Well, now when we put hydrochloric acid on here we have hydrogen coming out in the impurity, iron dissolving here (indicating) the chloride ions hooked up with the hydrogen ions to make hydrochloric acid. That is hooked up into the solution and you produce ferrous chloride. When you produce ferrous chloride in a piece of iron you have corrosion. So we do everything in this cell. We want to inhibit the action of the cell. We do everything to stop that from functioning when we put inhibitors in. The inhibitors reduce the amount of current flowing into this cell, cut it down and therefore the amount of iron corrosion is reduced because the amount of iron corrosion in this cell is a definite quantity of current for a definite amount of iron.

Putting the lead in, just putting in hydrochloric acid within a few hundredths of a per cent of hydrochloric acid on top of a piece of steel, we get the inhibiting effect with the lead along with the hydrogen. That tends to hold the hydrogen here (indicating) and we put into the cell a tenacious film of gas which has a high resistance and therefore a resistance which reduces the action in the cell. You cut down the current and therefore the corrosion of the iron electrode in this case. So the lead acts in that manner. That is the way which lead and copper act as inhibitors. They form a very imperfect film on the surface of the impurities that tend to hold the hydrogen in place, and that is what is sometimes called polarization and there are other terms used for it. There is a term here of over-voltage, which I have not gone into because I think it is too theoretical.

Mr. Owen: This is a sort of a first lesson, Your Honor. I think we will revert to it later and I want to go to another matter now, with your permission. I am reading from one of defendant's advertisements which was published in March, 1937, and entitled "Howco Method of Protecting Tubing and Casing Against Corrosion While Acid-

izing a Well." This quotation is rather lengthy but I have to get it to the witness in order to get the explanation.

(Whereupon the document above referred to was marked PX-186 by the reporter.)

Mr. Owen: Beginning on page 2 under this heading again "Howco Method of Protecting Tubing and Casing Against Corrosion While Acidizing a Well."

"This method consists essentially of using the steel of the tank as one plate of a large battery. The hydrochloric acid in the tank is used as the electrolyte, and installing another plate to form the other electrode of the battery.

"The well known principle of electro chemistry is where corrosion takes place an electric current is produced and conversely where no corrosion takes place no current is produced or if there is no current there is no corrosion. This principle is explained to some extent under the heading of "Passivity," paragraph 3, page 2322, Chemical Engineers' Handbook by John H. Perry, Editor-in-Chief.

"To make this principle easily understood we can refer to the ordinary battery, for example, the dry cell. This battery is made up of two electrodes, one of carbon, and one of zinc with an electrolyte to complete the cell. The manufacturers of such a battery have attempted to make it as efficient as possible, that is, to produce as much current as possible without it becoming polarized. To accomplish this a depolarizer is used. The manufacturers have done this in order to get the maximum possible amount of corrosion which means the maximum possible output of electric current since that is the object of this battery cell.

"If this same cell is constructed without a depolarizer and wires of sufficient size to carry the current are connected from one terminal to the other an electric current will flow. This current would continue to flow as long as corrosion takes place, but would stop very quickly if no depolarizer was used, due to the fact that the positive electrode would become coated with hydrogen, this is called polarization. As soon as the cell became polarized the current would stop flowing and no more corrosion would take place. If an in-

efficient battery is made, polarization will take place immediately. This is the object that is accomplished in the acid tanks. It is done by using a lead plate which has a higher voltage in the natural electrical scale than the iron tank itself. This plate is installed in the tank in such a way that even if a small amount of acid is present, the acid is in contact not only with the tank itself, but also with the lead plate. The lead plate at each end is thoroughly bonded to the tank to make the best possible electrical connection or short circuit. The lead plates in the tank contain over 30 sq. ft. of surface on one side, with both sides considered it is double that amount and this makes a huge battery cell out of the tank when acid is put in it to act as an electrolyte.

"If a tank was so made up and acid placed in it corrosion would immediately start and continue until the tank became completely polarized. This would mean some corrosion to the lead plates and also the tank.

"To save this lead electrode a temporary electrode is placed in the tank and current applied in the proper direction the first time the tank is filled with acid. This is done to complete the polarization in the least possible time, therefore preventing any corrosion that might take place before the tank has had time to become polarized. It is found in laboratory experiments that this voltage applied is not critical and even an excess current flowing will cause electrolysis of the lead, thereby plating the walls of the tank with a very thin coat of lead which only aids in the protection of the tank. After the tank has become thoroughly polarized it no longer needs attention to protect it from corrosion, because even if the tank should become depolarized in spots, with the large size plates a large amount of current would be concentrated at that point and cause very rapid polarization. After the tank has been prepolarized it is filled with acid and taken to the well to be acidized. On arrival at the well a heavy electrical conductor or cable which is well connected to the tank itself is then connected to the tubing or casing to be protected. This is only a means of

making the tubing and casing a part of the electrical system of the tank and should be used at all times whether the well is connected to the tank by pipe or tubing because sometimes flexible joints in the tubing may not make a good electrical connection.

"The voltage of the battery formed by the tank is thirty-five hundredths of a volt, therefore it should have a good conductor and as little resistance as possible in the short circuit so that this low voltage current can readily flow from one point to the other. After the tank is connected electrically to the well head the well becomes a part of this large battery and since the tank is polarized before arriving at the well no current is flowing in the system. After the tubing or casing is made a part of the system by connecting it to the tank the acid is started into the tubing or casing. The flow of current immediately goes to the part that is unprotected and is concentrated there, immediately polarizing it. After the acid flows down the pipe in the well, concentrated polarization takes place very rapidly at the point where the acid first comes in contact with the pipe and continues to at each new portion as the acid comes in contact with it. If we consider the lower end of the tubing in a well and assume that the acid has not yet arrived at this point, wherever the acid has been in contact with the tubing polarization has taken place and as the acid moves down to the bottom end of the tubing the polarization and flow of electrical current is concentrated at this unprotected point. The reason is that the acid having been in contact with the upper part of the tubing or casing, has already polarized that part of it so that no more current can flow to the polarized part and no corrosion can take place at that point. Therefore, the polarization will take place as the electric current flows to the lower end if the acid moves to that point and comes in contact with the tubing. The hydrogen that forms on the lower end or unprotected part of the tubing does so immediately when the acid comes in contact with the tubing at that point. It is not necessary for this hydrogen to travel from the tank down through

the column of acid to the point of contact on the tubing because the hydrochloric acid molecule that is in contact with the iron is immediately broken down by the electric current into hydrogen and chlorine atoms. The hydrochloric acid atoms that are immediately in contact with the iron are broken down into chlorine ions and hydrogen ions, due to the electrical potential imposed on the acid and the hydrogen ions released from the hydrochloric acid molecule cling to the pipe while the chloride ions immediately combine with the adjacent hydrogen ions, setting free other hydrogen ions which in turn combine with the adjacent chlorine, this all taking place immediately as soon as the current starts to flow. Therefore, one hydrogen atom is replaced at the contact point of the tubing and one chlorine atom at the contact point at the lead plate, all at the instant that the current starts to flow, therefore polarization and consequently protection is very rapid and the pipe is protected at all points where it is in contact with the acid. After the acid has passed on into the formation the pipe is still protected, due to its polarization remaining for some little time afterwards. It has been found by laboratory experiments that using a small steel tank, installing lead plates in it and placing hydrochloric acid in it, that the acid could be left for weeks without damaging the tank. That acid taken from this tank was not inhibited because it would immediately start corrosion if iron was placed in it.

"But so long as the lead plates were present and the electrical connection made the battery formed in this manner prevented corrosion from taking place and the acid was not active while these conditions were present."

Mr. Owen, continuing: Doctor, I wish you would state very briefly what you understand this advertisement to mean, and particularly with reference to the statement that the polarization of the truck tank is accomplished from an external source, and that the polarization of the well tubing takes place immediately when the acid comes in contact with it?

Mr. Lyon: If Your Honor please, to avoid any con-

fusion in the record, I would like to object to this term "advertisement." I do not know by what authority counsel states that this is an advertisement.

Mr. Owen: When Mr. Clason's deposition was taken, this advertisement was produced by him, and it was identified in connection with his deposition. Mr. Clason is here.

Mr. Lyon: Is it an advertisement?

Mr. Owen: Here is Mr. Clason. Let us ask him.

Mr. Owen: All I want from Mr. Clason is whether this circular or folder was distributed broadly throughout the trade.

Mr. Clason: It was distributed to our men, who I do not doubt gave it to some of our customers.

Mr. Owen: You sent quantities of these pamphlets to each of your stations, did you not?

Mr. Clason: Yes.

Mr. Owen: And they were intended to be handed out to your customers, or prospective customers?

Mr. Clason: Yes.

Mr. Lyon: Who was it written by?

Mr. Owen: I don't think it is of any importance. Well, who did write it?

Mr. Clason: Mr. A. D. Stoddard, vice-president in charge of our shops and plant there.

Mr. Owen: It expresses his views, as you understand them?

Mr. Clason: As an engineer.

The Court: What is that?

Mr. Clason: As an electrical engineer.

The Court: He is an electrical engineer?

Mr. Clason: Yes.

A. (Dr Prutton): The article which you have just read very definitely claims that the purpose of the lead plate in the truck tank is to inhibit the corrosion of the oil well tubing in the well, and claims that that is accomplished. The claim is also made that they polarize the truck tank with an external method other than just the lead sheet alone before placing it in service, and that the tubing is protected also by this electrolytic protection method.

Mr. Owen: Well, now, what is the fact, as you understand it, regarding the protection which is provided against corrosion in the oil well tubing due to the presence of the lead plates in the truck tanks of the defendant company? A. As a result of the large scale tests that I have made, which clearly show that the lead plate exerts no electrical protection effect, the reduction in corrosiveness which they apparently obtain in service in the tubing is due to the inhibitors contained in the acid, and not to any electrical effect. That is my conclusion, both from theoretical grounds and from the results of the many tests that we have run.

Q. And what does the presence of the lead plates in the tank have to do with the presence of the inhibitors in the acid which goes down the well tubing? A. The lead plate supplies most of the lead chloride content of the acid just before it goes down the tubing, and it supplies probably a majority of the copper content of the acid, the two, the two metals which are the inhibitors in the acid entering the well.

Q. Now, when copper chloride and lead chloride are in solution in hydrochloric acid, does it make any difference in the inhibiting effect whether they are added to the acid in the form of copper or lead chloride or are produced in the acid due to the presence of lead plates or other materials from which those chlorides may be produced? A. There would be absolutely no difference. The materials would be identically the same. If you take lead chloride and dissolve it in acid you get a solution. If you take a piece of lead and dissolve it in hydrochloric acid you get lead chloride, and if you simply dilute that with more acid you have the same thing which you would get by taking either solid lead chloride and dissolving it in the acid, or first dissolved the lead to make lead chloride and then putting it in the acid, and the same thing would follow with copper.

The Court: I think I would like to have the doctor point out the particular things in there with which he disagrees, if he disagrees with that article. I think I get it from what he said.

Q. Will you do that, Doctor? A. That is rather a long order. The explanation of the electro-chemical changes and how they take place in there are very unorthodox, and are written evidently by a man who is an electrical man, as they state, but not an electro-chemist that really knows what happens in a solution, and it is not hitched together in each little detail. The thing is quite garbled, and the whole story that it tells is completely incorrect, in my opinion.

The Court: I will accept that as the answer to my question without pressing it further. A. His explanation of breaking up of hydrochloric acid is not thorough. And the vague interpretation I would make of it is it is not even correct.

Mr. Owen: Doctor, referring to your large scale tests, in some of which you stated that you added lead chloride, copper chloride and iron chloride to hydrochloric acid in a steel, or in a stoneware crock, and in others of which you placed hydrochloric acid in a steel tank made to simulate that of the defendant company, and in those tests lead chloride and copper chloride and iron chloride were produced, did you find in those tests any different effect in those where you added the chlorides and in those where you produced them through the presence of the lead plate and the contact with the acid and so forth? A. We got substantially the same inhibiting effect whether the metal was placed in the acid dissolving the salts or whether we put the acid into the tank and let it dissolve the lead plate in the tank, producing the salts in the solution.

Q. Well, in this advertising literature which I read, I repeat this statement:

(Reading): "It has been found by laboratory experiments that using a small steel tank, installing lead plates in it and placing hydrochloric acid in it, that the acid could be left for weeks without damaging the tank. That acid taken from this tank was not inhibited because it would immediately start corrosion if iron was placed in it."

How does that statement agree with your experiments? A. I think that there is a slight element of truth in that

statement. In other words, if you had acid in this steel tank with the lead plate on the bottom, the lead dissolves, the copper dissolves, to make an inhibited solution, and you get some small amount of electrolytic protection on that tank, because the lead is so close to the iron there, just adjacent to it. But if you take some of that acid out and put it on iron, it would act on the iron. Any acid will act on iron, even when it is inhibited, as well as we can inhibit. There is always some action. And, therefore, to say that it would attack iron is perfectly correct, but it would not attack iron anywhere nearly as much as commercial hydrochloric acid would attack it. The acid is definitely inhibited, and that is incorrect in that statement that you read to me. It states that the acid is not inhibited, and I state that it is inhibited.

Q. Have you made any tests to determine the amount of protection against corrosion that results from the mercaptans found in Michigan crude oil? A. We have made some tests to study the effect of Michigan crude oil upon attack of acid upon oil well tubing, and the oil which we used was obtained from the Zahn well, which is one of the wells in suit, I believe, or in question here. I have the results of those tests.

Q. Will you explain those tests and the results? A. There were three different sets of test conditions. These tests were run upon the one-inch lengths of oil well tubing that I described before, that we used in our laboratory scale inhibition tests. We took chemically pure hydrochloric acid, and diluted it to 15 per cent, and measured the rate of attack of that 15 per cent C. P. hydrochloric upon the lengths of oil well tubing. We then took some 15 per cent C. P. hydrochloric acid, and added to it lead chloride alone in the amount of 340 parts per million of lead, and ran the corrosiveness of that acid upon the oil well tubing. We then took C. P. hydrochloric acid 15 per cent, and added to it 340 parts of lead, that is lead chloride, 380 parts per million of iron, in the form of ferrous chloride, and 3.8 parts per million of copper, in the form of cuprous chloride. So

we had three different acids that we used, the C. P. diluted, the C. P. diluted plus lead, and the C. P. diluted with iron, lead and copper in it.

Now, the first test was made without any oil being present. They were made without any oil present. And, of course, we took the—we measured the decrease in rate of attack or the percentage of inhibition of the acids, and we took the fifteen per cent C. P. as the reference point. There was a one hundred per cent rate of attack or a zero per cent inhibition. That is the reference point. The addition of 380 parts per million of lead in the form of lead chloride reduced the corrosiveness by 9.3 per cent. When the copper, iron and lead were incorporated in the acid, the reduction in corrosiveness was 62.1 per cent. That is the first series of tests run without oil.

The second series were run with oil in the test. The one inch length of oil well tubing was dipped into the crude old for several minutes, removed, and allowed to drain for several minutes, and then the oil-coated ring was placed into the test bottle containing the acid. The fifteen per cent C. P. hydrochloric acid, the inhibiting effect of this oil film on that particular sample reduced the corrosiveness by 12.1 per cent. In other words, this oil film on the pipe reduced the rate of corrosion by a little over twelve per cent. The acid that contained the lead chloride, when we placed the oil soaked length of oil well tubing into it, it reduced the corrosiveness by 21.9 per cent.

Q. As compared with what without the oil? A. Without the oil it was 9.3. In other words, there was about twelve per cent effect of the oil added onto the lead. In other words, the oil inhibition is additive to the metal inhibition. The lead chloride conferred inhibition and then the oil conferred additional inhibition on top of that.

The third test or the third acid was the chemically pure acid which contained, as I said, iron, copper and lead chlorides, and the reduction in corrosiveness was 70.5 per cent. The oil contributed to the inhibiting effect of the three metals present by 8.4 per cent. Now, the third set of con-

ditions was to take the acid which was to be used in the test and add to it two per cent of its volume of crude oil, shake the oil up with the acid, and then immerse the clean steel specimen into that oil emulsion in the acid. The first test using that method, using C. P. fifteen per cent hydrochloric acid, the reduction in corrosiveness was 20.4 per cent. Applying the oil in that manner reduced the corrosiveness of the acid 20.4 per cent. When the acid containing the lead chloride was used, the reduction in corrosiveness was 28.2 per cent. Now, if you will recall, the lead chloride and the acid without any oil present at all was about 9 per cent reduced. With the oil present, and the lead chloride, it is 28 per cent. The oil alone gave 20 per cent. And, therefore, the two are substantially additive. The inhibiting effect of the oil adds on top of the inhibiting effect of the metal.

In going over to the acid which contained all three metals present, and employing this method of shaking the oil up with the acid before immersing the sample, the reduction in corrosiveness was 75.7 per cent. Again showing that the oil contributes additional inhibiting properties to the inhibiting properties of the metals that are present in the acid.

Q. Were those tests made with agitation? A. These tests were made without agitation. They were made in the standard manner that I described previously under our laboratory test conditions.

Q. Doctor, referring to the defendant's tanks, will you state whether the formation of copper, lead and iron chlorides is a continuing process so long as the hydrochloric acid is contained in the tanks, and even after they have been initially polarized? A. The process continues, as shown by the fact that the acid in the polarized tank that we used in our tests picked up iron, lead and copper, and we have test data that shows the concentrations that were picked up at the end of one hour, and two hours, and there is a regular progression in the amount of metals picked up, and iron is one, lead and copper the others. It is not a regular thing in the sense of a nice, smooth curve, but it is in the sense that

you are comparing between different runs, and I am comparing in one run. We dipped out of this tank, at the end of one hour we took out acid, and we had some at the beginning; and at the end of two hours, and there was a constant increase in the copper content and in the lead content and in the iron content over that six hour agitation period.

The Court: There was not any drop at all? A. No, it was just a constant upward curve, showing how the regular solution of metals went into the acid.

Q. If the acid in the defendant's truck tanks did not contain these inhibitors, would anything result from the cable connection between the tank and the well tubing? A. If we had an uninhibited acid, that is, acid which had these metals in it, and ran it into the well tubing, and we had this lead sheet in the tank—would it protect? It is my opinion that it would not protect.

Q. The question was a little more specific than that, and that is, that if the acid in the defendant's truck tanks did not contain these inhibitors, even disregarding the presence of the lead plates for the moment, if the acid did not contain inhibitors when it leaves the tank, would this cable hook-up have any effect one way or the other? A. No, it would not.

Q. And if the acid does contain inhibitors when it leaves the tank, does the cable hook-up have any effect one way or the other? A. In my opinion it has no effect.

The Court: The whole answer to that in your theory is that it has iron enough to work on, without some more so far away. When you get all through with it that is about what it is, isn't it? A. That is correct.

Mr. Owen: And that whatever protection there is in the well tubing is due to the presence of these inhibiting agents in the acid as it passes through the tubing? A. Yes.

The Court: As I understand you, Doctor, that lead does do some good to the tank, or I mean to whatever—I leave out the word "inhibited"—from preventing the acid from eating the iron of the tank? A. I think it does some slight—has some slight benefit there, possibly reducing the rate of attack some twenty per cent.

The Court: When it gets over into the tubing it is so far away it doesn't? A. Yes. In the tank acid, as you recall, the acid leaving that tank is, according to our figures, 75 per cent inhibited due to the chemical inhibitors. Well, with 20 per cent electrolytic protection due to the lead plate and 75 per cent due to the metals in solution, the tanks undoubtedly last quite a length of time.

The Court: How much of that 75 per cent inhibition do you attribute, or do you attribute it at all, to the action of the acid on the lead during the time the acid is in the transportation tank? A. It comes from the lead sheet and possibly some small amount of copper might come from this tank.

The Court: You don't give any of it to the—any appreciable amount, what it does to the tank before? A. I think that lead that is on the side of it, and copper that they take and plate from this lead sheet in the bottom in their polarizing operation, and plate it on the side, partially plate up, I think some of that dissolves too.

The Court: How much will that do the year after next? A. I think it would be all gone in a year. I think it would be all gone in six months.

The Court: If they are right in their contention that is only done once during the life of that tank why, then, during most of the tank life you understand it is negligible? A. Yes, and that the protection, the polarization is not a major factor, and the chemical inhibition of the metals dissolved from the lead plate then is the major factor in protecting it and then some help is obtained by means of the electrolytic protection of the lead sheet, coupled with the iron. I would think they would get 40 per cent inhibition and possibly something like that with their 20 per cent electrolytic, and maybe 70 per cent from the chemical inhibition.

Mr. Owen: And the 70 per cent could be obtained by dropping in the lead chloride and copper chloride and iron chloride in the absence of the lead plate in the tank? A. That is correct. The result would be the same whether you added the lead chloride or let the lead plate dissolve; if you

got the same final concentrations you get the same inhibition.

The Court: But that isn't inhibited as much as the copper and the lead. A. That is right.

Mr. Lyon: I would like to understand the witness' testimony on that point. Is he saying that if we just hung the copper, the lead plate in the tank, in the acid, and didn't connect it to the bottom of the steel, or the wall, we would get the same protection for the tank? A. No, I did not say that. I said you would get, by electrically connecting it, you get additive effect. The amount of it I don't know, but I don't believe it is over a half of the effect.

Mr. Lyon: Suppose we just put raw commercial acid in our tanks, draw them out, but had this same lead plate suspended in the middle of the acid, not in contact with the walls of the tank. Would your testimony be that we would get the same protection? A. Well, I don't think in that case you would get the same protection.

The Court: No.

Mr. Lyon: Would you have the same amount of lead dissolve in the acid in the same length of time? A. I have explained you get some electrolytic protection.

Mr. Lyon: I am not asking you that. Would you have the same amount of lead dissolved in the acid in the same length of time? A. If you didn't have it connected?

Mr. Lyon: Yes; if you did not have the lead in contact with the tank itself? A. I think you would get somewhat less lead dissolved.

Mr. Lyon: How much less? A. I don't know. I don't think it would be over one-third less.

The Court: As I understand the theory, your reason for that answer is it would have farther to carry the lead to get to the iron? A. Well, no. The reason that I would give for that, if you just put the lead plate in the acid without making any connections to the wall of the tank, you wouldn't have a complete electrical circuit, and that the lead that would dissolve would have to dissolve by chemical attack on the lead plate.

The Court: You would have two connections between the iron and the lead, but either route would have to be through the acid. A. Yes.

The Court: You would have no direct metal to metal contact. A. No.

The Court: But you would have two routes. A. Through acid. And that is not a complete electrolytic cell, and the fact that I have said you get electrolytic protection indicates that there is current flowing through your cell when you have the lead plate in contact with the bottom, and that current flowing does dissolve more lead. So you would get more lead in solution with that cell in contact than you would without it being in contact.

The Court: In other words, you think one copper wire connected from the lead to the steel somewhere would do some good? A. Yes. It would do some good on this 20 or 30 per cent inhibition as I have admitted in my opinion, the electrolytic protection does help out in the steel tank to some degree.

Mr. Owen: Have you made any tests with a view to determining the effect of pressure on the action of the inhibited hydrochloric acid? A. We have made a series of tests on a laboratory scale to determine the effect of pressure upon the inhibition of various materials when added to hydrochloric acid solutions. The tests were run using prepared strips of strap iron that were immersed in a two-inch diameter glass test tube containing the acid, that glass test tube was placed inside of a heavy-walled alloy steel bomb and the pressure of one thousand pounds per square inch of nitrogen gas, which is an inert gas, was applied above the sample. And the loss in weight of the samples was determined under those conditions. We also ran a loss in weight of the strap iron in the acid in the two-inch test tube when exposed to the air, or open to the air, at atmospheric pressure, the same temperature and length of time test.

The general conclusion, and there is no major difference, is that the different types of inhibitors, with them you get the same relative reduction in corrosiveness rate at high

pressures as you do at atmospheric pressure. It is the same percentage reduction in corrosiveness. However, the actual corrosiveness of the acids is somewhat reduced.

In other words, same thing, C. P. hydrochloric acid 15 per cent, if that would lose one gram of iron during the test, at atmospheric pressure, under 1000 pounds pressure, why, that C. P. 15 per cent acid would dissolve maybe seven-tenths of a gram. But when you added inhibitor to the 15 per cent hydrochloric acid, you would get a similar reduction in rate of attack with the inhibited acid. So that the percentage reduction is substantially the same. If you want the figures I can give you a table of figures, but, if not, the general conclusion is simply that the rate of attack of the acid is reduced by pressure, whether the acid is inhibited, or not, but the percentage reduction in corrosiveness, the percentage inhibition remains substantially the same.

Q. You testified, Doctor, that 9.3 pounds of iron would be dissolved in one hour of contact between raw 15 per cent hydrochloric acid, in 1000 feet of 2-inch oil well pipe—at least that is as I understood your testimony. A. Yes.

Q. Can you state how much loss in strength to the acid contained in that 1000 feet of pipe would take place in dissolving 9.3 pounds of iron? A. The amount of acid that would be consumed in dissolving 9.3 pounds of iron would be 73/56ths of 9.3 or 1.3 times 9.3, which is 12.1 pounds of HCl would be consumed.

Q. How much would that reduce the strength of the hydrochloric acid, assuming that it was 15 per cent when the reaction began? A. Now you are assuming we just fill this tube with the acid and leave it for an hour. I will have to calculate the volume of that 2-inch tube to figure the amount of acid that it would contain.

Q. Well, Doctor, will you compute that and give us the answer? A. You want to know if I filled this 1000-foot length of 2″ tubing with 15% acid and let it stand for one hour, what reduction in strength would occur. I will compute it later. I prefer to.

Q. When you are making that computation, I wish you

would also apply your same calculations to seven-hour contact between the acid and the well pipe, the tubing being 3000 feet long and 2½" in diameter. A. I have the figures for 7.1 hours' contact, 3300 feet long and 2.66" in diameter. In this 7.1 hours of contact, 3300 feet length of tubing, and the inside diameter of 2.66", 273 pounds of iron would have been dissolved, 355 pounds of HCl consumed, or 265 gallons of 15% HCl would have been destroyed. The 265 gallons of 15% HCl would have been destroyed.

Q. And can you tell how many gallons of HCl would have been contained in that 3000 feet of pipe? A. I don't have that figure but if you ran through 1000 gallons you would get out 735 gallons of effective acid out of the bottom. If you ran through 500, 235 gallons of undestroyed acid out the bottom, substantially.

Q. That is, if it was raw uninhibited acid. A. Yes, attacking at the rate of 9.3 pounds, 2" pipe, 1000 feet long.

Q. And that rate of 9.3 pounds per hour in a thousand feet of 2" pipe is based upon the results of which of your tests? A. Of my blank runs using the diluted commercial acid without inhibitors.

Q. And those are your runs, 1, 1AA, 2A and 2C? A. That is correct.

Q. Tables I, II, III and IV? A. That is correct.

Q. Have you a chart showing the effect on the rate of corrosion of 15% commercial hydrochloric acid, both the raw acid and inhibited acid, based upon your runs? A. I have such chart. (Chart is produced.)

(The chart was offered and admitted as PX-187.)

Q. Will you please explain that chart, doctor? A. In this chart the upper line going across the chart indicates the corrosiveness of the 15% commercial hydrochloric acid without inhibitors, as measured in our large scale tests. The length of that line (indicating) indicates 100% corrosiveness, and referring to that acid as being 100% corrosive.

The amount of corrosion has been calculated for this

chart to be in these blank runs, or the runs made with the commercial hydrochloric acid, 485 grams of iron; that was the average that was dissolved from the oil well tubing by 100 gallons of the 15 per cent acid that was run through the tubing. That is taken as the standard of corrosiveness.

Now, when we run—when we add to the acid various amounts of copper, lead and iron, in the form of chlorides, we get a reduction in corrosiveness, and the amount of reduction in corrosiveness, the percentage reduction in corrosiveness in run 1-B, which we ran, where we took the 15 per cent commercial acid in the stoneware crock, and added the metallic chlorides to it, agitated them, and then ran directly from that stoneware crock to the piping system, there was 75.6 per cent reduction in corrosiveness, as compared with the commercial acid, or 75.6 per cent inhibition compared to commercial acid.

In run 2-B, which is shown in this third line, in which the copper content was 3.07 parts per million; lead, 316 parts per million, and iron 2315 parts per million, the reduction of corrosiveness was 66½ per cent.

In run 2-D, with 3.71 parts per million of copper, 455 parts per million of lead, and 418 parts per million of iron, the reduction in corrosiveness was 77.6 per cent.

In run 2-E, shown in the last column, with 3.8 parts per million of copper, 340 parts per million of lead, and 382 parts per million of iron, there was 89.1 per cent reduction in corrosiveness, as compared with the commercial acid used.

Q. Have you also a chart showing similar information in connection with your runs using the simulated Menaul tank or Halliburton tank? A. I have such a chart. This chart shows the reduction in corrosiveness that was obtained in these tanks employing the simulated Menaul type tank, and the first line of the chart, the first heavy black line indicates the corrosiveness of 15 per cent commercial hydrochloric acid when run through the piping system directly from the stoneware crock without the Menaul tank.

That is our reference point in our comparison of cor-

rosiveness. In this the corrosive effect of the commercial acid without any lead plates or anything in it is shown, and that is the rate of attack and it is 485 grams per 100 gallons of acid passed through the system, which is identical with the reference figures in the first chart.

(The chart was offered and admitted as PX-188.)

Q. That was the same basis as in PX-187, the previous chart? A. That is correct. Now, in the second line the figures for run 1-N are given.

Q. Now explain again what that run 1-N was? A. Run 1-N was a run made with the Menaul type tank in which the acid was 15 per cent commercial hydrochloric, which was run from the stoneware crock into the Menaul tank, agitated for about six hours and then run from that tank through the tubing system and the tank and the tubing system were connected together with a copper wire in order to practice the Menaul process of inhibiting the corrosion of oil well tubing. The conscript "M" in these runs indicates the ones that practice the Menaul process, and the number 1 indicates simply that we used the No. 1 series of tubing. And in this result we got 66.6 per cent reduction in corrosiveness, this particular test, with the cable connecting the tank and the tube. In the third line run 1-M is given, and in that the wire was disconnected, but the Menaul tank was used, same condition, other than disconnecting our wire. 68.8 per cent reduction in corrosiveness was obtained.

In run 2-M, that is, the fourth line, heavy black line, horizontal black line, run 2-M is given, the figures for it. That was the Menaul tank using the steel tank, the lead sheet in it, the tubing system, the electric cable between the tube connecting them together, as described in the Menaul patent, and in that test the reduction in corrosiveness was 70.8 per cent.

In the last horizontal line, run 2-N is given. 2-N is a run in which the cable was disconnected, the Menaul tank was used, and the number 2 signifies that Series 2 tubing was used, an entirely different set of tubing, and the reduction in corrosiveness in that test was 78.5 per cent.

So you can compare 1-M and 1-N, with the wire connected, 66.6, and with the wire disconnected 63.8. They are about the same. 2-M and 2-N can be compared, 70.8 with the wire connected and 78.5 with it disconnected. And if you average them up, why it shows that the wire does a little good and the other shows it does a little harm, but substantially the figures are within the accuracy claimed for these tests, and there is no appreciable effect of that copper wire, which is essential in practicing the Menaul process.

The Court: Have you ever run more than those two tests? I am wondering whether there was just the one. A. Of course, there are four tests there.

The Court: About half the time more and half the time less. In other words, it indicates it makes no difference. A. These were the only tests that we have run on the Menaul process. We have some other tests that were run but were not reported, and I think we are going to report those later on. That for some reason or other there was a deviation, for example, we ran one test in which we tried to run the acid through the Menaul tank so fast it could not be inhibited, and run it in and immediately run it out, but we found even in that case we got 50 per cent inhibition. In other words, we wanted to test its electrical effect with the whole set up connected, and we could not run it through fast enough to avoid contamination of the acid. And these are the tests that we have run.

Q. Now, Doctor, have you also a chart which shows the results of your tests, your laboratory tests, using C. P. hydrochloric acid? A. We have such a chart.

(The chart was offered and admitted as PX-189.)

A. In this chart, the reduction in corrosiveness was obtained by the addition of small amounts of copper, lead and iron to chemically pure hydrochloric acid, and the results are shown. In the first line, horizontal line, is shown the corrosiveness of hydrochloric acid, which is taken as one hundred per cent. Fifteen per cent hydrochloric acid is taken as one hundred per cent. Then, in the second line,

the results obtained with this fifteen per cent C. P. hydrochloric was taken, and 2.14 parts per million of copper were added, 242 parts per million of lead and 473 parts per million of iron were added in the form of chlorides. And when that solution was run in the laboratory tests the reduction in corrosiveness was 59.7 per cent.

In the third test, the third horizontal line, to the fifteen per cent hydrochloric, C. P. hydrochloric, was added the same amounts of lead and iron as we had in Test 2, but the copper was stepped up from 2.14 parts per million to 3.72 parts per million, and the reduction in corrosiveness, by increasing the copper from 2.14 to 3.72 parts per million, the reduction in corrosiveness which we obtained was 70 per cent on that sample. In other words, about 10.3 additional inhibition by the doubling of the copper content, or almost doubling.

Test 4 is shown in the fourth horizontal line. To the fifteen per cent C. P. hydrochloric acid was added 1.86 parts per million of copper, 510 parts per million of lead, and 473 parts per million of iron. The 1.86 is supposed to duplicate the copper content of Test 2. In other words, it is substantially two parts per million. The iron remains the same as it was in the first two tests, but the lead is increased to about double the content it had before. And the corrosiveness of that sample showed the acid was reduced 62.7 per cent. The inhibition was 62.7 per cent.

In other words, three per cent increase over that of the mixture in Test 2. Test 2 had two parts of copper and 240 of lead and 473 of iron. Keeping the copper and also the iron—keeping the copper at 2 and the iron at 473, and jumping the lead up to about 500, gave three per cent additional inhibition in this mixture.

In Test 5, as reported in the fifth column, or, in the fifth horizontal space, or line, 15 per cent C. P. hydrochloric acid, 4.18 parts per million of copper were added; 510 parts per million of lead; and 473 parts per million of iron.

The lead and the iron contents are identical with those reported in the acid used in Test 4. The copper, however, is about doubled.

The reduction in corrosiveness obtained with that acid is 71.4 per cent. The doubling of the copper content again reduces the corrosiveness about 8 or 9 per cent.

In Test No. 6, which is shown in the sixth horizontal line, running about two parts per million of copper, 1.86 to be exact; 204 parts per million of lead; and increasing the iron content to 1430 parts per million. That particular solution is supposed to be compared with Test 2.

Now, you see in Test 2, we have about 2 parts per million of copper, 242 parts per million of lead; and here we have 204 only of lead, but we have shown that the changing of lead does not greatly affect the inhibition; and this is about in the same order of magnitude. Now, we are increasing the iron, about tripling the iron concentration, and we get 61 per cent reduction in corrosiveness. If you will compare that with Test No. 2, you will see that they are about the same; 1.3 per cent is actually shown, but I think the method is—I think 1 per cent would be a permissible variation in tests.

Now, going to the last horizontal line, which is No. 7, we used 3.44 parts per million of copper; 530 parts per million of lead; and 1440 parts per million of iron. That should be compared with Test No. 3, although the copper is a trifle lower, but the lead is about the same—the copper is substantially the same, and the iron is about three times as great.

Q. The lead is considerably more, isn't it, Doctor, in Test No. 7 than Test No. 3? A. Now, wait a minute. Wait until I get this straight now (indicating). 7 and 5 are the tests that should be compared. In Test No. 5 there was 4.18 parts per million of copper; 510 parts per million of lead; 473 parts per million of iron. In Test No. 7 there are 3.44 parts per million of copper; 530 of lead. Copper is a little lower, but the lead is substantially identical with Test No. 5. The iron is more than tripled, just about tripled. So the net change is largely on the iron, tripling the iron. A reduction in corrosiveness is reached of 70.5 in this case, whereas up above there it is 71.4. There is a little more

copper in Test 5, and that would probably account for the difference. But the effect of the iron is shown to be negligible in these tests, there is substantially no effect by adding iron. Lead has some definite effect, and the copper has a very appreciable effect upon the inhibition.

These tests, the laboratory tests, if you compare those with the actual flow tests, they are very comparative; these figures all are of the same order of magnitude. In the laboratory tests we obtained about one-third to one-quarter as much corrosion with the inhibited samples, as we did with the uninhibited acid, and that same thing is true in the tube tests that we made. It is expected in the laboratory tests that we would get slightly lower inhibition because of the fact that there is no agitation in the laboratory tests.

The Court: Let me see if I understand you. In 4 why do you get more than you do in 2, and you have less copper? A. Why in Test 4 do I get more inhibition than I do in 2, when I have more copper? The copper was supposed to be made up to 2 parts per million in the samples. Our analyses shows, as given on the chart, the determination of copper is no more accurate than about .2 parts per million. Therefore, to all intents and purposes, these two samples have the same copper content. The amount of copper added was identical.

Mr. Owen: In Test No. 4 you had more than twice as much lead as you did in No. 2. A. I was coming to that. The copper was within the error of the method of analysis of about .2 parts per million. The lead about 3%. The increase in lead gave about 3% reduction in corrosiveness. Doubling the lead content gave about 3% increase in inhibition.

The Court: Have you got this close enough so that you, with your figures showing the combination, do you think you could work out figures as to how much corrosiveness you would have or how much inhibition, which is the same thing, without analyzing it? A. I think I could tell you pretty close if you wanted to know how many parts per million, if you said what inhibition would you get with 3

parts per million of copper, 400 of iron and 500 of lead. I could tell you that very quickly. The whole thing this shows in a general way is you get between 60 and 70% inhibition with acids that contain iron, lead and copper in such amounts as we got into our Menaul tank acid or in amounts reported in defendant's acid as taken directly from their truck tanks. These compositions cover the range of all those acids and the 10% would cover the whole group. In other words, once you get up to 2 parts per million of copper, a couple hundred parts per million of lead, you get to 60-70% inhibition. You may get another 10% if you double the copper, a little more by doubling the lead, but you are up near the optimum condition of inhibition with that condition of copper, lead and iron. These cover the composition of field samples of Dr. Bartell and cover the combinations of acids we got when we put it in the Menaul tank and shook it up for six hours.

The Court: I am looking at No. 6 and No. 4, and I am wondering why the more than doubling the amount of lead practically made no difference. What was your explanation about that? A. Test 4, the inhibition is 62.7 and in Test 6 the inhibition is 61. That is 1.7 per cent due to doubling the lead. There is not a great deal of change.

The Court: You are more than doubling your lead. A. More than double, yes. It is around two per cent change, and the other figure was three. But in all the tests we have run increasing lead up to about 200 parts per million you get about eight to ten per cent inhibition, and if you go above 200, going to 500, you get another one or two or three per cent, so it goes up to a little over ten as a rule.

The Court: What is your final conclusion about iron? A. That it has practically no effect whatsoever. You don't want to take these figures—I regret they reported these percentages in fractional percentages. The best thing is to take them as whole numbers, and the accuracy of an inhibition test isn't sufficient to warrant these percentages, and therefore I would rather stand on whole number differences.

The Court: I was treating 62 in 7 and 61 in 6 as being

practically the same. A. Yes. You see, Test 2 and Test 6 have about the same copper and same lead, and the iron is tripled, and it is 1.3 per cent difference between the two. And that is coming very close to the sensitivity of the method.

The Court: All right.

Mr. Owen: Doctor Prutton, did you run any other tests than those covered by your tables which have been offered as PX-187, 188 and 189? A. We ran several other tests which are not reported in the report involving running uninhibited fifteen per cent acid through a tubing system. Another test running it through the Menaul tank and then through the system, and one test in which, to the commercial acid, chemicals were added and then it was run through the tubing system direct, and those figures were not reported.

The general results of the tests, the first test run with commercial acid was run as a sort of a measure of how we could rely upon the—how constant would be the rate of corrosion of different lengths of oil well tubing, and we used a set of tubing which was not used in subsequent runs, and we found that the variation in corrosion of different lengths of tubing in that system varied by as much as twenty-five per cent. So we decided in subsequent runs to fix on two completely separate identical sets of tubing that we would follow through in the tests.

The result of the first test agrees in general with the blanks we ran on other samples, or on other tests. But since we did not follow through and run that same tubing throughout all the Menaul and other type tests, we did not include it. The rate of attack of the tubing in that first run was substantially the same order of magnitude as in the other blank runs. It wouldn't change the picture to any degree at all if it were included.

The second run that was discarded was a run that I mentioned this morning in which we ran fifteen per cent commercial hydrochloric acid through the Menaul tank and we tried to do it so fast that it would not have time to pick

up lead and copper. And when we finished up we found that about fifty per cent inhibition had been obtained by the exit acid. The acid from the Menaul tank showed 1.3 parts per million of copper which would account for about that fifty per cent inhibition. And since the result was not clear cut, that was not included.

Then a third test was not included in which we made up a synthetic mixture of these chemicals added to the acid, running directly from the crock through the oil well tubing, and when we got through with that run and analyzed the solution we found that some error had been made in the copper addition, and that the analysis showed about 1.4 parts per million of copper, and that particular acid also gave about fifty per cent inhibition, which is about what we would have expected.

Q. Did you run any tests with oil through the horizontal pipes? Your pipe system? A. We ran tests which were not completed. We put some of this oil from the Zahn well in the tubing, and then ran the acid through the system. The flow conditions that we got in which alternate solutions of the oil came out of the tubing with the acid, and the fact that our tubing system was almost horizontal, which would permit the oil to rise to the top of the acid, and the acid flow underneath the oil, and have a very thick column of oil up on the top of the acid layer, we came to a definite conclusion that those tests were not valid, they did not agree in any way with these laboratory tests of the inhibitions in the presence of oil as reported this morning. The inhibition was around 50 to 60% when measured, which we felt was due to the fact a heavy layer of oil floated on top of the acid, the acid had gone beneath it and we really only had half of the metal exposed. In our tests the velocity we ran acid through our system was a very low velocity—less than a half foot per second; when we pump acid down into an oil well in a treatment, the velocity you usually use is around 5 to 8 feet per second. At that velocity you get a tremendous amount of turbulence which scours oil off the tube; you have no turbulence at one-half foot per second—

it simply flows in a straight line. Therefore, we felt to make any valid tests to determine the effect of oil that might have been in the tubing we would have to go to a vertical system, to have a pump in the system that would give us the velocity, and we did not complete all the data on those tests because they were all experimental, to get any figures that were representative.

The Court: Is your rapid movement comparable to agitation? A. Very much so, yes. If you increase the velocity of a stream of liquid going through, you get a scouring action. The turbulent currents tend to scour off the oil. The more rapid movement, Dr. Bartell's tests have indicated that you get more rate of solution but you get a greater percentage of inhibition.

The Court: All right. That is attendant, on the one hand, with that agitation you get in your flowing down the well. You have your oil and your acid mixed, or not? A. In the horizontal pipe—the oil was at the top and the acid flowed under the oil.

The Court: Now, where would the oil be going down the well? A. If it went down vertically the slug of acid coming into a column of oil would hit a velocity of 5 feet per second and it would be scouring off. You have a slug in there in which the acid and oil mixed somewhat but the acid forces the oil into the tubing.

The Court: In each of those did you think you got a greater oil inhibition, in this agitated one, which would be like the well, or in the oil segregated at the top, and the acid flowing under it. Which do you think you would get the greater oil inhibition on? A. If the acid flowed down the vertical oil well tube at high velocity, and forcing the oil ahead of it, you would get a lowered effect of the inhibitory properties of the oil, a lower inhibition due to the oil than you would in my test where it was simply being run underneath a thick layer of oil that was covering over half of the pipes.

The Court: What percentage do you think the oil was to the balance of it? A. I really don't know what there was in this pipe.

The Court: I was thinking of a very small percentage, like the cream on a milk can, a little skim over the top, of the oil, to a substantial quantity of the acid, compared— A. (interrupting): In this test that we ran, or these preliminary studies to see just what happened when we flowed the stuff through the oil well tubing, the total volume was about six or eight gallons, and there were about two or three gallons of oil there, and it came out in slugs, there was a slug of oil came out every once in a while.

The Court: That would not compare to the total formation. As I understood you, and as I understand it, the oil would be comparatively still, and the other would be flowing under, and, therefore, if you stopped at any one time and compared the amount of oil to the amount of acid, you would not have any fair comparison as to the total percentage of the total amount that passed through the oil? A. I did not feel it was a fair comparison in the test that we could get.

The Court: I was wondering which way the oil worked, though. If it was agitated, you would get a comparatively small amount of oil over the whole surface, wouldn't you? That is, one part of your tube would have as much oil on it as the other? A. Yes.

The Court: On your agitated one? A. Yes.

The Court: Now, in the other, if you are right about the oil being comparatively still to the acid, and flowing under it, I should think you would get almost a complete inhibition right at the point where the oil contacted the tube, and I would think you would get practically no inhibition at the point where the acid contacted. A. That is exactly the reason.

The Court: Therefore I would want to know how much oil you had, how thick the layer of oil was? A. We had no means of measuring that exactly.

Mr. Owen: I understand in this test the doctor first filled the pipe with oil so that the oil was in contact with the entire surface.

The Court: I was in complete accord with him that it

was not comparable at all. I didn't know how you could get anything out of an experiment if you didn't have anything to compare it with. A. Can I answer that further? We had thought of setting up a vertical system. When we started to consider, well, if we want to do a thorough job we will have to repeat all the tests, taking in all of the different tests, it became such a complicated thing it would take years to do, and we feel that the laboratory tests are in general indicative of what would happen.

CROSS EXAMINATION

By Mr. Lyon: As I understand your testimony, the agent that constitutes the guilty inhibitor which you accuse in this case is actually the copper. Is that correct? A. The copper apparently contributes the major part of the inhibition.

Q. Well, I would like you to make that just as definite as you can. Is it necessary that there be any lead or iron dissolved in the acid in order for the copper to produce the effect that you have referred to in your testimony here? A. Copper produces alone the major part of the total inhibiting effect of the final acid contribution.

Q. Without the copper, according to your tests, what is the maximum percentage of corrosion, of reduction of corrosion that you could accomplish by dissolving lead or iron in the acid? A. I thought it would be 10 or 15 per cent. Variable figures were obtained, but 10 or 15 per cent is probably—I am not certain that when you take copper and add it to get an inhibiting power of 60 per cent, and then you add lead in a form so that the total mixture is up to 65, we will say, that the lead only does the 5 per cent job. I have no way of telling. There is no more reason for saying that the lead does just that additional 5 per cent than there is in—there is no reason for holding the copper constant and letting the lead take the burden of the decrease.

Q. If I understand you, it does not make much difference after you get up to 5 parts of copper per million

in the acid whether there is any more dissolved in the acid, or not, is that correct? A. I really cannot answer that question, simply because I think the highest concentration of copper that we have worked on has been a little over 4 parts per million; and apparently in adding copper to the acid, you get your major effect in the first two parts per million, and that the curve comes up rapidly in the first two, and then it tends to flatten off somewhat. In other words, we got about 60 per cent inhibition, as I recall here, with 2 parts of copper per million, and then if you jumped it up to 4, you got only about 10 more per cent.

Q. All right. Now, what can you tell us about less than two parts per million of copper? A. I can only tell you the indication I gave you on a large scale test in which we got 1.4 parts per million through and got about 50 per cent inhibition. In other words, going from 4 down to 2 dropped another 10 off.

Q. Have you any experience with 1 per cent? A. I don't recall we have any figures.

Q. So far as you know it is more or less a straight line relationship below 2 parts per million? A. No, I think that it drops off rather sharply in there.

Q. You don't remember the drops? You don't know where it drops? A. No. I would suspect around 1, but I don't know. In other words, we have gone as low as 1.4 and the drop-off is rather rapid. It dropped off about 10 per cent in going from 4 to 2, and from 2 to 1.4 it went down another 10.

Q. How long does it take this copper to dissolve in 15 per cent hydrochloric acid in the absence of any lead plate bonded to the steel? A. I don't have any idea. We made no tests on that.

Q. One part in a million of copper, or two parts per million of copper is not very much. Do you think you know whether or not you could operate in an oil well with hydrochloric acid in a practical way without picking up one or two parts per million of copper? A. Well, we obtained about six or eight shipments of hydrochloric acid from the

Graselli Chemical Company, which takes a bunch of commercial materials and runs it through a process, handles it several times and ships it out to us and the analyses we got averaged two-tenths of a part per million. I believe that same degree of handling should be carried out without much trouble if conventional methods were employed.

Q. Well now, how did this copper get in this acid in the tests you made in your laboratory? A. It gets in in two ways. Some comes in with the original acid. I don't know how that got in. Some of it comes in—considerable part, by the lead sheet dissolving, the copper associated with the lead dissolves. The rest of it comes in, I believe, from a steel tank which also contains some copper. All steels contain some copper. In the tests we ran the lead sheet in the bottom of the tank became coated with white coating, a lead chloride, that wasn't dissolved in the acid, would not show up in our analyses, and the copper that was associated with that lead reacted and then the lead chloride not dissolved, it is my opinion, went into the acid. In other words, a considerable amount of the lead sheet reacted, then went into the solution. Therefore, the copper going into the acid from the lead was an appreciable amount.

Q. Well, now, did you purposely buy lead plate for your test that contained copper? A. Yes, we did.

Q. Pick one out that had copper in it? A. We did.

Q. Why did you do that? A. Because we had definite instructions the Halliburton Company was using chemical grade sheet lead, which contains copper.

Q. What is a chemical grade of lead? A. I don't know. That is a term.

Q. Could you buy commercial lead plates without copper? A. I recall looking into the A.S.T.M. Handbook, recalling four different grades of commercial lead.

Q. Did any of them have any less content? A. As I recall very definitely there is one—at least one, grade that had practically no copper.

Q. And what was the price? A. I don't know. I was looking at the table of the American Society for Testing Materials.

Q. Are you satisfied if the Halliburton Company employed that type of lead plates in its tanks that it wouldn't obtain the effects which are complained of in this case? A. No. I think that the lead and small amount of copper there actually in conjunction with the oil contact you have in the tube all added to the effect, you still had inhibited acid.

Q. Your testimony then is the Halliburton Company couldn't operate its lead plate system for protecting its tanks without their necessarily somewhere in the system picking up enough copper so as to produce the effects complained of in this case? A. If you used commercial hydrochloric acid, such as normally contains a very minute amount of copper and lead, and if you had a steel tank that was relatively free of copper, if you used pure sheet lead, absolutely pure, I believe you still would be putting inhibited acid into the well when you got through with that; because we have shown definitely that with lead alone, you get a 10 or 15 per cent inhibition that is added to whatever your commercial stuff is, you add that 10 or 15 per cent inhibition, and then you are putting it down the well, and that lead has the property of cooperating with the materials in the well, to give you added inhibition, whereas a number of other inhibitors do not have that cooperative property.

Q. Now, was this property of copper, acting in the manner that you have pointed out here, as an inhibitor, known anywhere prior to its use by the Halliburton Company, do you know? A. I think copper is fairly well known as an inhibitor, copper compounds of various types. I do not recall, I cannot give you a reference, but I am quite sure that some inhibitors have used copper.

Q. Did you know that copper was an inhibitor before you studied this Halliburton system? A. Well, I have a vague idea that I did. I cannot recall that.

Q. As a matter of fact, it depends, does it not, on the relation in the electromotive series of copper to iron? A. I do not think that you can make any blanket statement on the electromotive series.

Q. You used to be able to before the announcement of Menaul's discovery, in the Menaul patent? A. The Menaul

patent follows exactly the teachings of electro-chemistry, at least in principle, as far as the protection of the tank is concerned; but it does not follow it any farther than that, due to distance and various conditions.

Q. You have read the Menaul patent? A. Yes, but I can't remember every word in it. I don't recall that it is.

Q. Didn't Menaul announce a discovery that in hydrochloric acid lead bore the opposite relationship in the electromotive series to iron from anything published before? A. It would be a discovery for any one unskilled in electro-chemistry, yes.

Q. Can you point to any literature showing that discovery before the Menaul patent? A. I can point to the fact that the electromotive force series is a series where each element is given a potential, with a sign to show its tendency to dissolve, but that number that is listed there is the potential of that element against a solution, a water solution that contains one ionic weight of that kind of metal, ions per liter, a definite concentration.

Now, we have equations that show how any voltage changes with the change in the ionic concentration of the solution, and it is entirely logical that although lead is shown in the electromotive force series slightly below iron, when you put it in hydrochloric acid where lead chloride is insoluble, and you get low lead ion concentration, it is possible to figure out what would be obtained.

Q. Didn't anybody ever announce the fact that it was so shifted in hydrochloric acid before Menaul, to your knowledge? A. I don't recall that they ever announced it, because it is one of those things that anybody skilled in the calculation could have calculated quite closely, and the facts that you get a very minute potential tending to give electrolytic protection through the lead and hydrochloric acid solution.

Q. Are you familiar with the fact in acting upon Menaul's patent application the examiner referred to Menaul's statement on that point as inoperative and contrary to scientific fact? A. I read the entire file wrapper,

and the examiner was not highly skilled in electro-chemistry.

Q. Well, then, an ordinary skilled man didn't know before Menaul's announcements of this shift in the electromotive force of the relationship of lead to iron in hydrochloric acid, at least you can't point to anywhere in the prior art? A. I believe that any college graduate that has taken a course in electro-chemistry would know that such a shift would occur.

Q. Now, what about copper? Do you think—where is it according to the text books made prior to Menaul's invention, in the electromotive force, relative to iron? A. It is down below iron.

Q. Always? A. It is usually below iron.

Q. Well, does it shift to above iron, now, in this system of the defendant's? A. Well, when we talk about these potentials we are talking about a solid piece of metal. When we are talking about the protection we get with copper that plates out slightly on the surface of iron, we are talking about not a solid mass of metal but just a few molecules stuck here or there. It isn't the same thing at all. We have no means of calculating, in an imperfectly covered surface of iron covered with a few molecules of copper, we cannot calculate the potential of the copper or of the iron. Therefore, we are talking about something that is indefinite and the question cannot be answered exactly.

Q. Well, according to what was published in the literature prior to Menaul's patent announcement, copper was below iron in the electromotive series, and if added to hydrochloric acid in the presence of iron should have increased the corrosion? A. That is right; that is correct.

Q. Now, can you show me any announcement to the contrary to tell you, until your own work or Dow's work, in examining the Halliburton system for this case? A. I believe that I could get you instances of where copper had been used as an inhibitor.

Q. Where? A. Well, I can't tell you offhand.

Q. Have you got it? A. No.

Q. As a matter of fact, neither you nor the Dow Company or the Halliburton Company knew of this effect of copper which you are relying on in this case until you did this work, or the Dow Company or Dr. Bartell did this work for the purpose of establishing the evidence in this case; isn't that correct? A. I don't believe that is. It is my opinion that the copper effect was known for years before. At the time of the taking out of the Grebe-Sanford patent, I believe.

Q. Will you point to some publication or published statement of that fact? A. I can't do it offhand.

Q. Well, how long will it take you to find? A. I think probably over night.

Q. All right. We will leave that and ask you to be prepared on that in the morning. Well, did you know it before you did this work? A. I believe I did.

Q. Before you started work on this experimental data, did the Dow Company inform you that that was the basis of their position in this case? A. I don't remember.

Q. You didn't discover this stuff about copper in this solution business independently, did you? A. No. I knew of Dr. Bartell's findings as to copper in the samples, and, as I recall, I knew that copper was an inhibitor in the right concentrations when used, and the thing seemed entirely reasonable to me, that it would inhibit. Otherwise, I would have questioned, possibly, the conclusion that had been made by Dr. Bartell.

Q. Why? A. If I believed copper was going to accelerate the corrosion, I would not have swallowed wholeheartedly his statement that copper was the cause of it. Therefore, I was quite sure at that time that I knew that copper was an inhibitor, if used correctly.

Q. Well, you can't find that in any literature, can you? A. Well, I hope to. That is what I said I hope that I can bring in tomorrow morning for you.

Q. Now, how does the copper work? Do you know what its system is or mechanism by which it accomplishes this inhibiting action? A. I believe that both copper and

lead work somewhat similar, and that is that in the dissolving of the iron that hydrogen is plated out on the anodic portion—or, I mean, the cathodic portion of the metal, and that an imperfect film of copper and lead are deposited on those areas that hold on to the hydrogen, and build up a hydrogen over-voltage or polarization that stops or reduces the corrosive cell.

Mr. Owen: May I make a statement here, right in connection with this discussion of the inhibiting value of copper, Your Honor, plaintiff will show that the Dow Company used a copper chloride as an inhibitor for hydrochloric acid in acidizing oil wells for two or three years prior to the date of the Menaul invention. A. That is undoubtedly where I learned of it, and possibly from the literature too.

Q. Is it your testimony then that just putting copper chloride in the solution, without any lead plate, without any galvanic cell action, would accomplish this same inhibition, of the same order of magnitude? A. It would accomplish some inhibition.

Q. How much would you have to put in? A. Well, I think we have shown here how much you have to put in. You have got to put in a couple of parts per million.

Q. Of copper chloride? A. In the form of copper chloride.

Q. Is that all that you have to do? A. Just a few parts per million, and you have got about 50 per cent inhibition, approximately.

Q. Well, now, you were discussing the action of the copper in this plating mechanism, and you mentioned the plating of a film of lead or copper. Is it actually necessary that there be any such film at all to accomplish the reduction in corrosion, or may that be accomplished without the plating action of the metal, simply by the polarization? A. Unless you change the surface of the metal, you cannot get any difference in polarization; and, therefore, that is the basis upon which I am stating that some of that metal must be deposited to change the nature of the surface, so that

it can hold on to that hydrogen better. If there is no change whatsoever in the surface, you would not get any change in polarization.

Q. Wouldn't you get a hydrogen film? A. You would, but it would not take the high back EMF that stops corrosion, or the high polarization. You would get a slight film that would escape in the form of bubbles, and not be held on there tight.

Q. Now, you criticized the statement of the defendant's chief engineer this morning as read to you. I am going to read to you the paragraph commencing at line 38 on page 3 in the Menaul patent covering the defendant's system, No. 2149617. I think Your Honor has a copy of this patent. First I call your attention to the paragraph commencing at line 55 on page 3, reading "The method of this invention may also be applied to the treatment of tanks or other containers in which acid is stored or shipped, a suitable plate of metal having a more negative external potential than iron in the acid solution, for example lead, is suspended in the acid, then connected with the wire of the steel tank either with or without the medium of a battery or other source of low voltage current. As shown in Fig. 5, for example, the iron tank 12 may have a lead plate 13 in electrical contact with the bottom of the container. Such contact may be obtained either by riveting or burning the lead into place. It is to be remembered that the lead plate or lining should not cover the entire interior surface of the tank but only a part thereof so that the acid contained therein may contact with both the lead and the sheet iron. Desired polarization of the interior of the tank is thus attained." Now, do you disagree with that statement? A. No, I think that is true to a degree.

Q. Well, now, I will next ask you to turn to the paragraph in the next column, commencing at line 37, reading:

"It is remarkable to note that casing many thousand feet from the lead plate 15 is pacified. The explanation for this may be that both the acid and the casing are good conductors of electricity, but it is believed that an additional

factor is involved, namely, that as soon as one part of the casing becomes pacified, the resistance of that part immediateely goes up. This is in harmony with the theory that a film of lead or hydrogen or both is formed on the iron since such a film would present a higher hydrogen overvoltage and likewise cause a high resistance to develop. This would increase the current density adjacent other parts of the well. A film would tend to form wherever it did not already exist and once formed would tend to cause the current to flow from the acid to the casing somewhere else which in turn would tend to cause the formation of a film there, and so on, every part of the casing being protected as soon as that part is contacted by the acid."

Now, as I understand your criticism of this paragraph, you do not believe that the forces considered or involved would permit the current effect to reach down the well or down the pipe, is that right? A. It is my contention from theoretical grounds and from the results of the tests that we have made that that action does not occur down to great distances into the tubing.

Q. First with reference to the results of the tests that you have performed, have you examined those tests as to their possible range of error so that you could tell us within what permissible range an effect of the type called for by Mr. Menaul in the patent might have been present in your tests and not been detected? A. It is my belief as a result of the tests that there was absolutely no electrolytic protection due to the lead plate and the hypothesis of the method given in this patent to describe what was claimed to have taken place.

Q. Don't you care to answer my question? A. I can answer it, if you would be very specific as to exactly what you want.

Q. Well, just read—do you want the question read again, and you ask me anything about it you don't understand. A. Let us have it.

(Question re-read.)

A. As I recall, I made the statement that the ac-

curacy of our tests was possibly somewhere in the range of variation of 50 or 70 grams of iron in a test. Now, the fact that in our blank runs we got about 1000 grams of iron dissolving and in these tests with the inhibitors added and in the tests with the inhibitors present the Menaul patent contemplated, we got substantially the same figures. That is the basis on which I decide the electrical connection had no effect.

Q. That isn't an answer to my question. A. That is as close as I can come to answering your question.

Q. You are able to take your own work and from your work report a possible range of error, is that correct? A. Why, I think that is correct, but I can't give you an exact figure. It is 9.1% or 9.2%.

Q. Isn't it true on its face it is not any more accurate than within 20%? A. It all depends on the way you look at it. You are looking at it from the bottom up and I am looking at it from the top down.

Q. If it is accurate only in 20%, the possible percentage of reduction in corrosion, this Menaul effect might exist and not be detectable in your test within what range? A. You mean in reduction of corrosiveness?

Q. In per cents of reduction of corrosion, if your work isn't accurate below 20%. A. It is more accurate than 20%.

Q. Let's assume it isn't. A. Why assume that? I claim it is within 5%. I think it is closer to 5% on the reduction of corrosiveness. It isn't exactly 8 or 10. It is somewhere around 10%—5 to 8, and 5 to 8 is probably closer.

Q. Will you look at your tables, PX-187 and 188 and compare run 2-E, PX-187, with 1-N on table PX-188, and 1-M on that table? What is the percentage of error between those two tests? A. In the first place, the oil well tubing was entirely different in the runs. You have to compare the ones and twos with the same number; you can't do it otherwise with the tubing; you can't cross-compare for the tubings.

Q. You have averaged the runs up there for 100% corrosiveness, haven't you, in both tables? A. That is one of those average of averages that is approximate but not too good. I have stated between oil well tubing you get a difference of 20% and that means between the two sets of tubing you can't cross-compare. You have to compare one to the other—you have to compare within the one set, and then you compare No. 1's with No. 2's.

Q. Does that mean—within what range could these findings of yours differ within the results that you could get from different oil well tubings, or different lengths or combinations of oil well tubings? A. I have said that the rate of corrosion of one length of oil well tubing with any acid might be 20 per cent different than the results of another length, and that is why we used the same tubes in a series of tests; you have got to compare the ones marked No. 1, with each other; and the ones marked No. 2 with each other.

Q. What is comparable in your tests then—you should not compare the No. 1 runs with the No. 2 runs? A. No.

Q. They should not be compared? A. There the difference might be 20 per cent between those.

Q. You have got to compare the No. 1's with the No. 1's? A. Yes.

Q. You haven't got any No. 2 runs with the same amounts of materials present, for comparison as to their accuracy? A. Do you mean in these—oh, none of the Menaul patent. We have got two 1's and two 2's, but you mean any test where they ran the synthetic—

Q. I mean, in the Menaul— A. (Interrupting): Here are two 1's and two 2's (indicating).

Q. Well, they have different amounts of material? A. Not a great deal.

Q. Have they got enough to account for the difference in the results? A. Not much. I don't think you would get a great deal of difference between the concentrations that you have there (indicating).

Q. How do you know that you would not? A. I don't

know, but with that little difference in copper, I would expect it to explain some slight difference here (indicating).

The Court: Let me ask you this, doctor. I was taking a tubing X and tubing Y, and you make up two different compounds of acid and we will call one of those A and we will call another one B. Because one of them—they will all have hydrochloric, both A and B have got hydrochloric in them, and both A and B have got copper, but we have shifted different amounts; and they have both got lead, but we have shifted so that A and B, while they contain the same three elements, they don't contain them in the same proportion. Now, you have got X and you have got Y, two different commercial pieces of tubing. Now, if I apply A to X and Y, and I find that, we will say, X is consumed faster than Y, does it follow that if I apply B to X and Y that X will go faster than Y, or are there some combinations upon which you will get the reverse in the consumption? A. It is my recollection from our data that there are no exceptions to that rule, that you will always get the relative positions. Fairly close. Now, the differences that are being discussed here between 4.3 in test run 1-M, and in run 1-N, 3.25 parts per million of copper, can explain any differences between those two, due to that difference in copper. We have shown when it gets up near 4 it sort of flatens out, that is, that the curve is flattening out, and that the difference we would expect from that is not very great; it might amount to a couple of per cent here, and I am willing to admit that. I am willing to admit these numbers are off four or five units, and I have said there could be a five to eight per cent variation in our test results.

By Mr. Lyon:

Q. Will you explain the difference between run 2-E and run 2-B on the other exhibit, PX-187? What is the per cent of difference there between those two? A. The percentage of difference is from 66½ to 89.1. The difference is 22.6 per cent.

Q. Now, how do you account for that? A. Well, this

particular one contains .73 parts per million more copper and it is down lower in the range where the effect of copper cutting off seven-tenths of a part per million makes a greater variation, and that would account for some of this difference.

Q. How much? A. I don't know.

Q. Well, now, what is the per cent of error, do you know, whether it is actual error, in comparing those two runs? A. No, I don't know. It would cut back the difference somewhat, probably 15 points, or something like that, in error.

The Court: Do you think if you had analyzed these—that gets back to a question I had previously—and I suppose there are so many different comparisons that you haven't analyzed that I could find some new ones, but this is the same question. Suppose before you analyzed 2-B, that combination, made that test, and before you had made the 2-E, how close do you think you could have come to telling what the percentage of reduction in corrosiveness would be on 2-B, and how near do you think you could have come to telling how close it would be on the other? A. I think run 2-E is possibly one, and the comparison there is possibly one that shows the greatest variation in the series between those two.

The Court: You actually ran this and you are giving me the actual figures? A. I would think you could tell within five to ten points, which is about the figure that I gave you before. Now, I might miss it a little greater than that, but I don't think so.

The Court: You don't think you would have gone lower on 2-B, you don't think you would have guessed lower than 60, or higher than 70 then on that. You think you would have gotten it that close? A. I think so.

The Court: And you think on 2-E you wouldn't have gone that far? A. I wouldn't have gone that high, because that is a little higher inhibition than the rest of the figures would indicate would come. I think that is a little higher inhibition. That is up in the upper end of the

thing. I would cut back five to ten points on that, and call it 70 to 80 or 80 to 89, somewhere in there.

Mr. Lyon: I still want to talk about comparing 2-E with run 1-M.

The Court: All right.

Mr. Lyon: You tell me that is a different pipe? A. Yes.

Q. You have figured the particular pipe for determining percentage of corrosion on PX-188 for run 1-M as against the pipe that was run and called that 100 per cent, haven't you, or you have averaged it out, the difference in those two pipes? A. Yes.

Q. How can you account for the difference between 66.6 per cent reduction in corrosiveness for run 1-M where you have 4.33 parts per million of copper, and the results of run 2-E which we have just been discussing, where with a less amount of copper you have 89.1 per cent reduction? A. Just in the nature of the tubing. That is the only explanation I could give you. It is different tubing.

The Court: We have taken the same acid in each? A. Substantially.

The Court: You have taken the amount you would eat 100 per cent to start it with? A. Yes.

The Court: Well, then, it seems as though that—you have already accounted for all the differences in your tubing right there, in that difference in the 100 per cent? A. No.

The Court: I take it one would eat more than the other? A. It wouldn't account for all the difference. It would account for half the difference here. If your rates of attack are known for two sets of tubing and average them, you are half way off.

By Mr. Lyon:

Q. Did you do this, Doctor, or did somebody else inflict it on you, this average of averages you have got in these tables? A. I believe somebody else inflicted it on me. I don't remember. I think the field of comparison is on one side of the tubing and to simplify the thing it was thrown together.

The Court: Well, then, that is the only average of averages, that top line? A. The top one. The rest are individual, and we are comparing an average of averages of attack on these blanks.

The Court: For the purpose of getting at what I was asking you about we should have that performed with the same acid in both cases, and take what they eat as 100 per cent? A. Yes.

The Court: Isn't that right? Then we would get at what I am talking about. A. In one set of tubing we got about 1000 grams and the other set about 800, and there was 20 per cent difference between the two sets of tubing, and so what we have done at the top figure, we have averaged up those two rates of plain acid and to compare the individuals and it is not a valid comparison and produces some little difference.

The Court: We can't get at what you are getting at at all? A. The whole question is entirely an academic one in that we are showing these acids are 60 to 80 per cent inhibited, plus or minus 10 per cent, and that is the story, and to argue on differences of 5 to 8 per cent is simply wasting time.

Mr. Lyon: If it is plus or minus, if these results are plus or minus 10 per cent we will say— A. (Interrupting): No, I wouldn't say that.

Q. I thought you did. A. I said a range of 10 per cent. All of these acids are different. All lie within 20 per cent outside range of inhibition, and they are all very highly inhibited.

Q. Well, your statement is, as I understand it, that your tests with the Menaul tank system, which you have already described, establish that there is no effect of connecting the tubing to the tank, unless it be within the limits of error of the tests that we have been talking about, is that correct? A. The limits of error I hadn't fixed exactly.

Q. You haven't fixed them? A. I haven't fixed them exactly, and there is no effect of the Menaul process on the portion of the tubing.

Q. Now, you have stated that, on a theoretical basis, current cannot get down the pipe, or get the acid down the pipe? A. I say, the probability that it is going to climb down that acid through a tremendously high resistance, when it has got other and a lot easier ways to go, I say the probability is so remote, and we find such a small amount of current flowing between the pipe and the tank, that most of that current undoubtedly took the easy way, and the minute amount, a trillionth of an ampere might have gone down to the bottom of the well, but I cannot tell for sure that any amount did that was effective to do anything.

Q. This is purely a matter of opinion as to how much of that current gets down? A. It is purely a matter of opinion, based upon a knowledge of the flow of electricity in certain circuits, and electrochemistry, and an agreement with the results of these tests which we have run.

Q. Isn't the resistance of the acid low enough so that theoretically the current could get down appreciably down the well, even 5000 feet, assuming that the formation of the film on the walls proceeds as the acid goes down? A. That question was asked by Judge Tuttle, in which he questioned the relative conductivity of the metal and the acid, and I gave him the figure, I said that the acid was not as conductive as the metal. I gave him a figure, but I guessed at it. I have looked that up, and instead of the metal being 5000 times as conductive, it is 100,000 times as conductive as the acid.

Q. Where did you find that? A. Those figures are from the handbook.

Q. Will you just get your handbook and tell us what the resistivity of hydrochloric acid is, 15 per cent? A. The reason I could not make any certain calculation of this is that in talking of the resistance of metal, we used specific resistance. In talking about solutions for theoretical consideration, we talked about equivalent conductance. You cannot convert one into the other—to convert one into the other is a difficult thing to do so that it can give you an exact figure. This is the Handbook of Chemistry and

Physics, Twenty-Third Edition, and the equivalent conductance, page 1529, the equivalent conductance of aqueous solution of hydrochloric acid is given as varying in different concentrations of solutions from—a very dilute solution of 379, and a one-tenth normal solution of 350. And from that you can calculate out that the specific resistance of hydrochloric acid, if you take a centimeter cube of hydrochloric acid and apply a potential of one volt across two opposite parallel faces, when you have a resistance of one ohm, a current of one ampere will flow, and that is about the resistance of this hydrochloric acid. It is very close to one ohm.

Now, if you take a cubic centimeter of steel, on page 1531 of this book, steel is given as varying, different kinds of steel, but here is one steel, 10.4 times 10^{-6} ohms centimeters. That is the resistivity of it. In other words, 10 times 10^{-6} is 10^{-5} or 1/100,000. Its resistance is but 1/100,000 of an ohm for such a cube of steel. And a cube of hydrochloric acid has a resistance of one ohm. That is the ratio of the two.

Now, in a well there is a bigger cross-section of hydrochloric acid than there is of metal and it becomes difficult to calculate the exact ratio of conductance.

Q. Would you think that the resistance through this 5,000 feet of hydrochloric acid, fifteen per cent, that the value of, say, 4,000 ohms was about right? A. You have to know the diameter of the tube and everything else?

Q. Two and a half inch internal diameter oil well tubing. A. Well, let's see, two and a half inches would be about—how long a tubing was it again?

Q. We have been talking about 5,000. We might as well see if the currrent will get down there. A. All right. I will figure this out.

Mr. Lyon: If Your Honor please, aren't we entitled to look at the books recording the actual experiments to which the witness is referring? I asked him to produce them. Who has got the books? A. Right over there. Mr. Lightfoot, have you got those two books? Give them to Mr. Lyon.

Mr. Lyon: Now, we were trying to figure the resistivity of the acid down—what the total resistance would be in ohms for 5000 feet of acid in a 2½ inch bore? A. You gave a figure of 4000. I came closer to 5000.

Q. It is somewhere between 4000 and 5000 ohms? A. Yes.

Q. Now, did you determine what the available voltage is, effective voltage is that is created in the system in the Menaul type of tank? A. Yes, I have those figures.

Q. About the order of one-tenth of a volt? A. An average of a couple hundredths of a volt.

Q. What is the figure in the Menaul patent, without taking the time to look it up? A. I have seen figures of 35/100ths in this.

Mr. Owen: I would like to have you refer to your notes, Doctor, and give the exact figures. A. I will give the exact figures. Do you know where the voltage is mentioned in the Menaul patent? I can't pick it out right offhand.

Q. You start in and give us the voltages that you found and I will see if I can find the voltage in the Menaul patent. A. All right. Should I read these figures?

Q. Yes, if you have them. A. When the tank was full in run 1-N the millivolt difference between the tank, which was at the start of the test, the millivolt difference in potential between the tank and the pipe was zero, and the microamperes—

The Court: Tell me what that means. A. That means the difference in voltage. You put an accurate voltmeter between the two and there was no potential difference between the tank and tube and there was no current flowing at the start of the test. When the acid had fallen down from 40 inches deep in the tank to 34⅛th inches deep, in other words, when about one-sixth of the acid had gone through, the millivoltage, the voltage between the tank and tube was 1.2 millivolts. That is .0012 volts. And the tank was negative. And the micro-amperes that was flowing at the time was 2½.

When it was 26½ inches—28½ inches of acid left in the tank—I can't make that number out. It may be 26 or 28. It is not typed very clearly, but the tank was about one-third empty at the time, there was 1.8 millivolts difference in potential between the tank and the tube. The tank was negative, and 5 micro-amperes was flowing through the electrical wire, 5 micro-amperes would be five millionths of an ampere.

The Court: What was it in millionths? A. Micro.

The Court: Five in a million? A. Yes.

Q. You were telling about this wire now? A. Yes.

Q. What I am interested in is the voltage that is set up in this circuit in the tank? A. You mean inside of the tank?

Q. Yes, between the lead plate and the acid. A. I couldn't make any measurements there.

Q. You didn't make any? A. We couldn't.

Q. You could have. A. How? I would like to know. I couldn't figure it out myself. Maybe you can tell me.

Q. I should have asked you, couldn't you? A. Not with my knowledge.

Q. There is no way of determining the available voltage in this galvanic cell that is created in this tank? A. Well, I entered the work in this lawsuit with the idea that we were going to see whether this tank with the lead in it inhibited the corrosion of the tubing. I was not interested in the tank, so I didn't even give it much thought, but just offhand I couldn't tell you how exactly to measure that in that peculiar shaped fashion.

Q. The point is that you did not measure it? A. I did not measure it.

The Court: When you measured the wire, that does not measure the other current? A. It does. It absolutely measures the current.

The Court: It is your theory that it would measure it, and it is your theory that it would not? A. May I state this here, we measured the amount of current that flowed into the copper wire from the tube to the tank. Now, that

is the current that had to go down in the acid, in the tube, and then come back through the tube back to the tank, and that is what we were interested in. He asked me whether we measured the current that flowed through the lead plate. We didn't do that.

The Court: Your theory is that that goes from the lead to the iron, through the copper down into the tubing and back through the acid? A. No.

Mr. Lyon: That is just wrong if that is his theory. A. It is just the reverse. It goes from the lead to the—in order to do any protecting, it would have to go from the lead up through the acid, inside of that tube all the way down to the bottom of the well, back through the well tubing and back into the tank. In that circuit we put a microammeter and measured how much current was flowing in the tubing, and it measured the amount of current that went down to the bottom of the well.

The Court: I have been misstating everybody's theory. I had—all I did was make the current flow in the wrong way. Of course, it has got to flow in one way to make it deposit on the lead. A. Yes, Mr. Lyon, with our theory.

Mr. Lyon: You are in general agreement? A. But the question you have in mind is did we measure the amount of current that went from the lead plate to the walls of the steel tank. That is the question.

Q. Through the acid. A. Through the acid to the walls of the steel tank. And the answer is, we did not.

Q. As a matter of fact, just to clear the matter up about this current coming back up from the bottom of the well through the oil well pipe, in effect the system, the tank and the pipe are both grounded, are they not? A. Yes.

Q. So you have got a circuit from the— A. (interposing): Did you say the pipe and the tank were grounded?

Q. Yes. A. The tank is not grounded.

Q. It could be. A. You have it on rubber tires on an automobile.

Q. Connecting to the pipe is the same effect as grounding the tank, isn't it? A. It is connected through another electrode to the ground.

Q. Yes. A. But that is not the same as grounding itself.

Q. I understand. But when this tank is connected by this cable to the pipe you are accomplishing what you would accomplish if you grounded the tank? A. Yes.

Q. And the pipe is grounded? A. Yes.

Q. At the well, is it not? A. Yes.

Q. So that the path of current is from the lead plate—is from the ground through the lead plate, through the acid, to the tank, to whatever metal you are going to protect, isn't that it? A. From the lead plate through the acid to the tubing.

Q. Yes, to the ground. A. No. Some of it comes back.

Q. It is grounded, though. A. And the amount, you can't predict or calculate the amount.

Q. Now, that is what I am getting at.

The Court: Then you only got part of it when you measured your copper wire; is that right? A. The amount is, which I would expect to flow to the ground, is not a great deal. The voltages that we have here are indicative of the driving force tending to drive current from the tank with the lead sheet in it, through the acid into the tube and into the ground, or, it is rather—

Mr. Lyon (interposing): Well, now, suppose we are interested in whether or not we are getting any protection at 5,000 feet down the well. Are you able to state what the magnitude of potential would be or would have to be to set up down there in order to polarize? A. I can't tell you that.

Q. Well, you can't actually prove, can you, that there is not sufficient current there in this system? Theoretically in your opinion there isn't but you can't prove your point. A. The potentials that we have measured, the currents we have measured are all so minute, the patent talks about 3/10 of a volt, or 2/10 or 1/10, and here we find one thousandth of a volt to drive current down the acid, and it is impossible, in my opinion, that any much greater amount

of current than what we measured went down that well bore. I don't know what the patent said. I am just saying it indicates an appreciable voltage, but your advertising literature said 35/100 of a volt. It doesn't—

Q. (interposing): The patent doesn't say anything about tenths of a volt. A. It doesn't?

Q. I can't find it. A. I assume it said an appreciable voltage.

Q. It says in an ordinary cell the voltage causing the current which is required for polarization is very low, being about 100 millivolts. He says that at page — A. (interposing): That is 1/10 of a volt. I think that is where I got the idea of 1/10 of a volt. When measured, the voltage was one thousandth of a volt.

The Court: Where did you measure that? A. Between the tank and the tube.

The Court: Well, in the copper wire there? A. The copper wire was temporarily—put this across the ends of the copper wire, we put a millivoltmeter and it measures the difference in potential that occurs across there.

The Court: Where was it you got that two and a half to five? A. Two and a half microamperes flowing through the copper wire. The quantity of electricity flowing.

The Court: And what is the one and— A. (interposing): Millivolts?

The Court: Yes. A. That is one thousandth of a volt. That is the electrical pressure that is tending to drive current from this lead plate down through the acid in the tubing, down to the bottom of the well, that one thousandth of one volt.

Mr. Lyon: Now, you have said you can't tell us how much electrical pressure or potential would be required down the well in order to polarize it, the pipe. Is that because you haven't determined it or is it because it could not be determined? A. I can tell you that in the electrolytic protection of pipe lines that they have to use .3 volts, and that is standard practice, and I can give you many references to it that are well known and accepted. If you

get below .3 volts they get imperfect protection, and the amount of current that they use to accomplish that portection is a considerable amount. These figures are negligible compared to those figures actually used in that electrolytic protection.

Q. I am not asking you that. If you would just follow my questions, it is somewhat difficult for me to phrase them in this technical subject, I think we could make better progress. I asked you whether or not the fact that you answer that you did not know what potential or driving force was necessary to polarize the pipe at 5,000 feet was because you hadn't ascertained it or because it could not be ascertained? A. We did not ascertain that.

Q. Could it be ascertained? A. I don't think it could be easily ascertained. You could, in a laboratory, set up some sort of apparatus, but to try to astrabalate from that down to the bottom of this well, with the complex electrical conditions that you would have to figure, would be no practical figures whatsoever, and I made no attempt whatsoever to do that, and we feel that these figures being so minute down to the millionths of an ampere, and thousandths of a volt, are so negligible—if you would take that rail out here in front of the lawn you would find one thousandth of a volt difference between the different ends of it, and there is not supposed to be any electricity flowing in it, and the amount is so negligible that as far as I am concerned there is no electrical flow there.

Q. Well, Doctor, as a matter of fact, even that order of pressure or potential, say one thousandth of a volt, is not enough to accomplish the polarization, you say? A. I would state that it would be my opinion that it would not be anywhere near enough to establish polarization, but I can't tell you on the basis of any exact tests.

Q. Well, then, your testimony that there could be no current flowing down the acid in the well sufficient to produce a polarization anywhere down the well, is purely a matter of opinion and speculative opinion at that, not one that you are able to prove? A. No, it is on the basis of

my knowledge of electro-chemistry of electric circuits and the results of these tests when made with oil well tubing that showed if you had that pipe polarized in the tests we made, polarized sufficiently to do any good, we would have a sufficient amount of iron dissolved but we got no noticeable difference.

Q. Subject to the limits in your error, of course? A. I have stated the limits in error.

Q. Now, are you testifying that the current wouldn't be sufficient to cause any polarization in 5000 feet? Are you of the same opinion the same difference would go all down to the ground? A. I would say within 50 feet of the connection any polarization you get would be negligible. I might admit it within a few feet of the wire and in the tank I have admitted it definitely, but even that is stretching my imagination considerably.

Q. Let's talk about the tank a little bit. In the first place, would it make any difference, if so, tell us, if a copper plate was substituted for the lead plate that is bonded in this tank? A. If you put a copper plate in place of the lead plate, I don't know what it would do. I think that your copper would dissolve, some of it would plate out upon the iron, and whether it would plate out in the correct form to do inhibition, I don't know.

Q. I thought you told me a little while ago there wasn't anything to Menaul's announced discovery of the shifting in the electromotive series of lead and copper in hydrochloric acid that any school boy or high school graduate could not predict from calculation. A. Offhand, on copper I can't tell you. You have to get solubilities of copper, hydrochloric acid, coefficients, and with that information it would be possible to go through and make calculations.

Q. Don't you think the first man that had ingenuity or sense enough to do that in the case of lead was entitled to discovery? A. I would say he is entitled to discovery if he had patented his discovery, but he patented the use

in an oil well. He discovered you could protect the tank with a lead sheet. He casually mentions it in the patent.

Q. Casually? Figure 5 shows a tank. A. Well, that method is treating an oil well.

Q. Well, Mr. Menaul was working with a company engaged only in the treating of the oil well business. A. May I read a part of the patent—"A method and apparatus for handling acidic solutions." The examples, there is only one case where it shows the tank alone with the lead sheet. There are three, four illustrations showing methods of using it in oil wells.

Q. Different, aren't they? A. Somewhat different. But it implies in the description, the specification is readily practical on protecting the tubing and casing and parts of the oil well.

Q. What do you think he should have patented as a discovery? A. A storage tank with a sheet of lead. I think he should be given a patent on that.

Q. You do? A. Yes. I think that had some little element of invention on that. I don't want to qualify as a patent expert.

Q. We are not suing on it so you don't have to worry about that. What would happen if you substituted a copper sheet for a lead sheet? Why can't you tell us that? A. Because I don't have the data needed to give you that.

Q. You think you could calculate it? A. Yes.

Q. Sure? A. I believe so.

Q. Do you know what might happen? A. No.

Q. What do you think might happen if you put a copper sheet in that instead of a lead plate? A. I can't tell you.

Q. What do you think happens in this system of the defendants to the tanks if the bond disappears between the lead plate and the bottom of the tank? A. I would believe if the bond disappears that you would get less lead and copper going into solution, and that the tank, because you would not have—you would have a lower inhibition due to lead and copper in solution, and you would have elimi-

nated this small amount of electrolytic protection, but you would get a more rapid attack on the tank, and the tank would dissolve.

Q. How fast do you think, comparatively? A. I couldn't tell you that. That is an impossible question to answer.

Q. Why not? You have made all of these measurements? You have studied this system? Why can't you tell us how long an average tank would last with this system? A. That is like asking a geographer who has made a study of Michigan to tell you how China is put together. He knows the general hills, the valleys and the mountains, and he knows the contour of Michigan, but that does not mean that he can tell you about China.

Q. Let us say that the tank is inhibited 60 per cent in one case, and 99½ per cent in the other. What difference would there be in how long they would last? A. If those figures were—well, it would mean eight times as long as the other.

Q. Now, as a matter of fact, have you inquired at all as to how long these defendant's tanks last? A. I have not been interested in how long they last.

Q. Would you think it probable that the defendant is still using the same tanks that it started with in Michigan in 1935? A. I think it would be highly improbable, from our tests, that they are using the same tanks, if they only polarized them once.

Q. Do you think that it would be necessary that they be polarized more than once? A. Yes, that is my opinion.

Q. Are you quite sure of that? A. No, I just say it is my general—I can't tell you exactly, but in our tests we had so much iron dissolving from the tanks, the Menaul type of tank, which we polarized once, that apparently that protective coating of the lead that you plated on when you polarized it was taken off, and it was not quite as good a job.

Q. Maybe you didn't do a very good polarizing job. A. Well, we bought a brand new automobile portable stor-

age battery, about 100 amperes an hour capacity, and put the thing in and let it go overnight, just the way the defendant did in polarizing their tanks and we used one of these little tanks, instead of using 1000 gallon capacity tank where the surface would be greater.

Q. I won't ask you to be responsible for my statement that the tanks are still in use here, the original tanks, and there are no facilities for polarizing here when they are made at Duncan. I won't ask you to be responsible for that. Can you estimate how long a tank would last in ordinary service if this lead plate was not bonded to the bottom of the tank?

Mr. Wiles: Mr. Lyon, how frequently is the witness to assume the tank is used, how many hours a week?

Mr. Lyon: How many hours do you think it would last with acid in it? A. I couldn't tell you that.

Q. You couldn't? A. No, I couldn't tell you that.

Q. Now, let me see something about these tests you have run. You took the freshly polarized tank and conducted your check tests in it with commercial acid first? A. We took the freshly polarized tank and washed it out thoroughly, and then we prepared the 15 per cent commercial acid.

Q. You washed the tank? A. Sure.

Q. Did you do any scrubbing with this wire brush that you were talking about? A. Absolutely not.

Q. You didn't? A. We might take that polarized lining off if we did.

Q. And you ran that acid down this tubing for testing? A. Yes. Then we put the acid into this Menaul polarized tank and stirred it every fifteen minutes with a big, heavy glass stirring rod about four feet long, by hand, without scraping the sides, for the six hours, and then we started to run the acid through.

Q. That took about three and a half hours? A. Around three hours.

Q. And that was what you called Test No. 1? A. I don't remember.

Q. 1-A. I was trying to get your system there. The one relates to the tubing? A. 1 is the tubing system.

Q. A is the test with the commercial acid without anything in it? A. I don't know the numbers there. I can't tell you.

Q. After you got through with that test what did you do? A. You mean after the Menaul test?

Q. Let us go back to the tests you made at the beginning when you just used the crock? A. Yes.

Q. The first test you made? A. Was commercial acid through the tube.

Q. Then what did you do? A. Then commercial acid in the Menaul tank.

Q. How long did you leave that commercial acid in that tubing uninhibited in that first test? A. In the tubing?

Q. Yes. A. I didn't leave it at all.

Q. I mean it took three hours to go through, didn't it? How much did you put through there? A. We put 200 gallons through in each test.

Q. You put it in at the rate of a gallon a minute and took it out at the bottom at that same rate? A. Yes.

Q. That took how many hours? A. Three hours.

Q. Now, then, when you got through with that test, what did you do next? A. Then we ran with the wire disconnected.

Q. No, I haven't got any tank in this. I have got the crock. And you are just running the commercial acid. A. We took the commercial acid in the crock, adjusted the temperature, then ran it through the tubing system. That was our blank. Just commercial acid through the tubing.

Q. Yes. A. That is one test out of the way. We got 1000 grams of iron. The next test we took the 15 per cent commercial acid in the stoneware crock, blending it up to the right strength and temperature. We ran that through a Pyrex tube down into this Menaul tank which was sitting somewhat below to the side of it and kept it in the Menaul tank for six hours, during which we gave this occasional stirring, and then at the end of that six hours in the

Menaul tank with the wire connected to the tubing, we transported at the rate of one gallon a minute through that tubing, down and out the sewer.

Q. All right. Was that the same tubing you used in testing for the commercial acid? A. That is what the 1 refers to. The 1 refers to the same tubing which was used in the commercial acid, the Menaul acid and so on.

Q. How many different tests did you make with this No. 1 tubing altogether? A. I would have to look through our records, but I think that there was several. I think there is one or two tests, maybe not even that number, that were made on the No. 1 series of tubing that are not shown on these charts.

Q. In all these tests you have the acid in there about three hours? A. The time of running it through the actual tubing system was three hours and 180 gallons was run through.

Q. How many tests did you make with this tubing altogether? A. On one set of tubing?

Q. Yes. A. About five or six.

Q. How many of those tests were with raw commercial acid? A. Two.

Q. Now, did you do anything to the tubing between those tests? A. Yes.

Q. What did you do? A. We took the tubing out, we washed it out and filled it with 15 per cent commercial hydrochloric acid, let it stand for an hour, dumped that out, washed them out again, put solvent through to dry it, and then we reamed the tubes out with this stiff, hard wire brush and put a burnished surface on the inside of the tube, and took all loose metal out, and we got a condition more or less reproductive of the surface of the inside of the tubing.

Q. How thick was this tubing, ordinary oil well thickness? A. Well, it was 2.4 pounds per foot of length and it was about 1/8th of an inch thick.

Q. Am I correct that this tubing got—was subjected to a good deal of action from hydrochloric acid? A. Not a great deal.

Q. It was not? A. We ran two preparations.

Q. That would be seven hours? A. Two preparations, that is six hours.

Q. Six hours. Now, let us talk about that. Did you find the tube was still in good shape when you got through with those two runs? A. Well, it was pitted after those runs.

Q. Badly? A. It was definitely pitted in that time and I couldn't tell how badly, but at the couplings the threads were pretty well chewed up.

Q. Did you have to put new threads on? A. No, we simply tightened them up a little more.

Q. As a matter of fact, your tube was in good enough shape so that you could start out and still use it, couldn't you, after all these tests? A. But these tests have no relation—

Q. I am not asking you to argue. A. To perform this test and put in service these—

Q. I am not asking you to argue about anything. The tubing was still in good enough shape to make more tests? A. I would say that it is not.

Q. It is not? A. Yes.

Q. Isn't that it? A. I would say that we were getting right close to the end. There are threads right on the lengths of tubing, and the acid has eaten into the collars. The last times we made the tests, there would be a drop of acid coming out of it, and we couldn't tighten it up.

Q. After your first test, the first time that you ran the raw acid through the tubing, it was still in good enough shape to continue to make four or five tests, isn't that correct? You did make four or five? A. Well, we did, sure. We felt it was good enough for that purpose.

Q. You say it was pitted. Did you get all of those pittings out of there by your treatment? A. I believe we did. The surface, when we examined the tubes after drawing the stiff wire brush through, was quite highly burnished; it wasn't exactly smooth, but most of the pitted effects had not been completely smoothed out, but at least

somewhat smoothed out. We couldn't see in any too great a length in the pipes. We could see in for six or eight inches, possibly look through the whole length, but not to look down into the pits.

Q. How do you know that there were serious pits in there? A. I did not say that there were serious pits in there. I said it was pitted looking. In one run of these Menaul type acids, and inhibited acids, it showed a matte finish that did not have this pitted effect, it was much smoother.

Q. How deep were those pits? A. I couldn't tell you that. We made no attempts to measure it.

Q. You could tell that by just running this wire brush through there? A. We got a substantial number of them out by doing that, and the surface of the tube was, we felt, substantially the same as the surface before, but there may have been some of the pits remaining. I do not know.

Q. Did this tubing get noticeably thinner in all of these tests now that you have made, four, five or six tests of that tubing. A. We only ran two tests for three hours, with a total of 360 gallons of uninhibited acid, and that did most of the corroding, so the actual time was only for six hours, and I don't know just how thick it was left, but if you figure how thick a layer of iron is—well, we took off that tubing in the two uninhibited acid tests, we took off about four pounds of iron.

Q. And how deep was that? A. I think you and Dr. Bartell figured out something on that, a few thousandths of an inch. But we did not take it off uniformly. It was very definitely in the uninhibited acid.

Q. If the corrosion is not going to work uniformly, but is going to work in concentrated areas, what happens to the effectiveness of an inhibitor if it is only, say, what you call fifty per cent inhibited? A. I do not know what kind of an answer you want me to give you to that question.

Q. Well, as you concentrate the corrosive effect of your acid you are concentrating any residual corrosive effect of your acid, are you not? A. As you concentrate the acid?

Q. The action of the acid; assume that the acid will get in particular areas more than an average over the whole pipe? A. The general consensus of the—the result that I have seen by observation of these laboratory tests is that when you use uninhibited acid, you get this pot-marked or pitted effect; and when you use inhibited acid, you get a smoother surface not nearly as much eaten away.

Q. But that is not what I am asking you at all? A. No?

Q. We have been talking about this on the basis of trying to get an effect of this corrosion, on this uniform effect over the area of the metal that the acid is acting on, and you suggested that they ought to start this out as expending itself more violently in particular areas. A. Well, I have explained here in discussing the theory of corrosion how corrosion usually, unless it is inhibited, does do this pitting action. It attacks these areas that are annodic and therefore you are to expect pitting at these high potential places. When you put inhibitor in that, you have a smoothing-off effect.

Q. If that is true and your acid is going to act that way you are not going to get much good out of 30, 40, 50% reduction in corrosion, are you? Just think that over. A. I think you would. I think it would be very effective as compared with the uninhibited acid; you get a less pitting.

Q. Would you? With only a 50% reduction in corrosion? A. Yes.

Q. If acid is going to concentrate at a certain point— A. (Witness interposing): These acids ran up to 60 or 80, the ones with lead and copper, and they gave a smooth finish.

Q. Well, if you are in danger of having pitting, can you stand for an acid that is 10 or 20 times as corrosive, as effectively, say, so far as 99% inhibited acid is concerned. A. I would hate to answer that question because it involves too many guesses on my part. I would think that it would be very much superior, very much superior than the raw acid. The raw acid, particularly if used with inhibition to

get this 50% effect, a type of inhibitor that cooperates and gets an added effect of a small amount of oil left in the tube so you might start out with 60 to 80% inhibited content, and that same amount left in the tube picks up to 80 or 90%, you get very good results.

Q. The judge suggested a while ago putting something in this acid so it won't burn your hands. Does 15% hydrochloric acid burn your hands very quickly? A. It doesn't burn my hands. I don't know, someone less accustomed—

Q. (Mr. Lyon interposing): Let's take a sulphuric acid. A. 15% sulphuric?

Q. Let's take an acid that would burn. A. It might.

Q. Let's take a normal sulphuric acid; that will burn your hands fairly quickly, would it not? A. It will burn fairly quickly, yes.

Q. It will burn so quickly just diluting it 50% or adding the inhibitor the judge had in mind earlier in the day in the case wouldn't do you much good, would it? A. What do you mean? Adding 50% water? Cutting its strength in half wouldn't do much good.

Q. I can take my hands and put it in commercial sulphuric? Well, if I have the wrong example—what I am getting at is this: Suppose you had an acid that had marked burning effect on your hands, and when you got through cutting it down 50%, that effect, it still would burn your hands very badly. Now, then, if you had a sore on your hand so that the acid could cut it down 50%, that effect, it still would not do you any good at all, would it? A. I don't think the analogy has any relationship. It is just like asking me what would happen if I drank a bottle of sulphuric acid.

Q. All right. You have a lot of figures here about per cent corrosiveness. Tell me how much damage to an oil well pipe, as a practical manner, putting down some 3000 gallons of acid, or commercial hydrochloric acid, at the rate of say 750 gallons an hour, is going to do to that pipe. For how long do you want to put it down there? A. I am

going to put it right down, all down at the rate of 750 gallons an hour.

Q. In one hour. A. 750 gallons in the first hour, 750 gallons the second hour, and another 750 gallons in the third hour. Four hours, then?

Q. Yes, 15% hydrochloric acid. A. I can only tell you on the basis of assuming the rate of dissolving the metal is the same.

Mr. Lyon: I don't know.

Q. Do you contend these figures of yours have significance tied to oil wells? A. Yes, I think they do. I can't answer that without figuring it out. I have to assume the rate is the same as here because I have no experience with that.

Q. Do you believe it would be? A. Yes.

Q. Is it true you know of no other tests except pouring it in the tube at the rate of one gallon per minute, taking it out at the rate of a minute? A. That is the test we made.

Q. The only one? A. We made one test, one test which I described and tried to put oil in. We ran a little faster than that at the beginning but as the oil solution came out we decreased.

Q. Why didn't you try the different rates of velocity? A. First, 1¼" is the smallest tube available to be purchased; second, stoneware crocks only come in a certain size. We couldn't get more than this 250 gallon crock into the doors of our building. We figured an average acid treatment might be 300. So we put in a 200 gallon crock, 250 gallons—we could put about 200 gallons of acid in it, and if you ran a 1¼" pipe 3 hours you get 60%, approximately.

Q. You say something about an average oil well treatment? A. That is more or less hearsay in discussion with Mr. Rebbeck and others.

Q. As a matter of fact, you talked this all over with the Dow men before you ran them. A. Surely, I told you I had.

Q. They told you different ways. A. Yes, and I sug-

gested three hours. They didn't mention that. I say I said, let's take three hours, which shows this condition. We did not understand any other condition whatsoever.

Q. You understand 3 hours is the time it takes to acidize a well, to take the acid down the well and out of the pipe? A. I think that is a convenient time. I have heard of times that run over a day, much less than a day—you can't average those things. It would be trying to figure out how long it takes to shoot a duck. It may be a week and it may be a minute. You take the middle. That worked out in this 250 gallon crock which we could buy in Akron, and we started our tests and made those conditions. We made no preliminary tests whatsoever.

Q. What effect do you think it would have on your figures, any of them, if you acidized a well in the same length of time but you put about between 2500 and 3000 gallons of acid through the pipe? A. Well, it would depend on the inside surface of the pipe. Give me a specific case. I can take the average rate of attack in this tubing and figure it out for you.

Q. Do you think the rate of attack would be the same? A. I think very close to it.

Q. How do you know if you haven't tried it? A. Well, this is oil well tubing. We studied the various factors that entered in affecting the rate of attack. The figures we have obtained I think are close to what you have obtained.

Q. Does the amount of agitation have anything to do with the figures? A. I think with agitation you get a higher reduction in corrosiveness.

The Court: You don't mean that, do you? A. Higher percentage reduction in corrosiveness, for the inhibited acid. When you agitated the samples and agitated C. P. acid, the rate is increased, more attack on the steel, more attack of the C. P. acid on the steel.

The Court: The rate of corrosion is— A. (interposing): Yes. That is the C. P. acid. Now, when you take the inhibited acid and agitate it in a piece of steel, the rate

is increased, but the ratio of the two, this one, does not increase as much as the uninhibited acid.

The Court: But they each increase in corrosiveness. A. As they get higher turbulence.

The Court: By agitation. A. That is correct.

The Court: They each decrease in inhibition? A. That is correct.

Mr. Lyon: What about commercial acid? A. Because it is trying to scour off that protective coat on the surface, and keep thereby increasing the rate of attack on the metal.

Q. You have answered as to the C. P. and inhibited. What is the answer on the same point as to the commercial hydrochloric acid? A. The information we have obtained is that the commercial acid we used in our tests is not much different than the C. P. acid, and therefore there is a very low percentage difference in rate of attack.

Q. Is there any difference? A. I said up to 6½ per cent was the maximum, and most of them were zero to one or two.

Q. Well, now, you admitted that agitation is going to make a difference. A. Oh, I think it would; surely.

Q. Then there will be a difference in the amount of agitation and in the kind of agitation where you are pumping at the rate of 750 gallons an hour down a pipe or where you are pumping at the rate of 60 gallons an hour? A. Absolutely there would be a great deal.

Q. And also considerable effect on the acid. How will it affect the amount of reduction in the strength of the acid that issues from the bottom of the pipe? A. With the higher velocities I would anticipate you might get a greater rate of attack on the metal surface, but that the percentage of acid that was spent in going through, if you take a given length of pipe, it would probably be a little lower.

Q. Well, now, wait a minute. A. It would be a little lower.

Q. A litt! or a lot less. Find out how much difference do you think in the amount of corrosion, compared to your tests, would be made by this different rate of feeding

the acid through the pipe? Do you think it would double the corrosiveness or add two hundred per cent to it? A. I don't know. I really don't know. I haven't studied the velocity effects, and I am just—in the laboratory tests we ran without any agitation we got about five or ten per cent less inhibition than we got in running it at a foot per second, but I don't think you could keep on adding ten per cent for every foot per second velocity added, because pretty soon you would be over 100 per cent. I think it tapers off.

Q. You don't know where? A. I don't know where it tapers off; we haven't made any tests.

Q. In other words, is there something about the making of the—or the effect on the strength of the acid that would be brought about by running down 750 gallons of acid in the same length of time you ran down 60? That is a completely different order of magnitude than any differences due to the agitation, you can see that. A. Well, as I said before, if you started out with fifteen per cent acid in a given piece of tubing, and a given length of tubing, and ran that fifteen per cent acid through at the rate of 750 gallons per minute, you would get some reduction in the acidity. What it is I won't say. But if you ran it through at the rate of 250 gallons per minute, you would probably get a greater reduction in acidity, you see.

Q. You don't want to say what the comparative magnitudes of those would be? A. I could figure it out, if you would let me use those figures, the average rate of solution of the pipe.

Q. No. A. I have to have something to start with. I have to have some numbers. I can't express it in terms of acts.

Q. That would be, such a figure, just figuring. A. I can't.

Q. I want to get an answer that adds some facts to the case. Well, now, you were going to, I believe that I indicated I wanted you to tell me even in your tests what the percentage of concentration of the hydrochloric acid was that you recovered in your tests at the bottom of the tub-

ing. You say it was fifteen per cent hydrochloric acid at the top. A. Yes.

Q. What was it at the bottom? A. Well, in these tests, of course, which were made in this very short length of tubing as compared to an oil well tubing, the amount of iron that dissolved was about two pounds, a little over that or a little under, so take two pounds. A gallon of hydrochloric acid, if you let it spend itself on iron, will react with just about one pound of iron. One gallon of fifteen per cent hydrochloric acid. And therefore we ran through about 180 gallons of acid and two gallons out of that was expended in attacking the tubing. Now, if we have a tubing 5,000 feet long, we would have fifty times that amount, or fifty times two gallons would be 100 gallons, approximately.

Q. I am not asking that. I am asking what was the actual reduction from fifteen per cent in the actual tests that you made? A. That would be two gallons of 180 were consumed, and that is a little over one per cent, so a little over one per cent of the acid would have been consumed in that short length of tubing. The acid would have fallen off from 15 per cent down to about 14.84.

The Court: You are asking really for a qualitative analysis, I take it. A. We didn't analyze it.

The Court: He figured how much iron he got and how much hydrochloric acid would take that off.

Mr. Lyon: That is satisfactory to me. But it reduces it in the strength.

The Court: I don't know whether there would be a way of making that qualitative or not. A. There would.

The Court: That would be the effect.

Mr. Lyon: Yes.

The Court: I don't know whether it would come out by the same balance or not. A. I think you will admit the method—your men will admit the method of calculation.

Mr. Lyon: I am not asking you that. The difference between the strength of the acid as you put it in at the top of the well, and as you take it out at the bottom, with the raw commercial acid down your pipe, was a difference be-

tween 15 per cent and 14.83 per cent. A. As I explained to you the length of tubing was 100 feet long. If you did that to one that was several thousand feet long, you would have twenty, forty, or fifty times that amount of reduction.

Q. I am talking about your tests.

The Court: He wants to know what it was in yours. A. Fifteen to sixteen hundredths of a per cent. If that is the question.

Q. If you had a long well, the length of the well would be a factor that would vary that, and the rate at which you pumped the acid down the well would be another factor, would it not? A. Well, why vary two variables? Why not stick with one variable? One variable is the length. Let's leave the other variables the same.

Q. If you increase the velocity of the well, that will tend—increase the velocity of the acid, that is the length of time the acid is in the pipe, a given amount, why that has the effect of reducing that difference, doesn't it? A. From all that I could tell you, or what would be, if you keep the figures the same I could tell you exactly or very close your reduction in acidity, which would be very appreciable.

Q. Well, now, I think from your calculations of the loss in 1000 feet of 2-inch tubing, 2½ inch tubing, which you said was 9.3 pounds loss—well, what would you calculate to be the depth of the corrosion of that type? A. 9.3 pounds of iron?

Q. Aren't those the figures that you gave? A. I think that is about right. It wouldn't be very much. It would be this few thousandths of an inch. I can calculate it if you want me to.

Q. It would be in the order of a thousandth of an inch? A. I don't know. It might be three or four. If you figure that it was all uniformly attacked, and there was no pitting—

Q. Just a minute. What percentage of the tubing by weight would that represent? A. I don't think it would represent a great percentage by weight, but it might make a critical effect on the strength of it.

Q. Well, that is all I want, what percentage of weight would that be, of what order? A. If you take five thousandths of an inch, and 3/16ths, you would have, oh, that would be about 1/30th, or, no—about 1/50th, something like that.

Q. Oh, let us get it more accurately than that. A. Let us take the—have you got the thickness of the 2-inch tubing that you want me to figure on?

Q. It is 6.4 pounds per foot? A. Well, I can't tell you how thick it is from that. I can't tell you how thick it is.

Q. But you know that 6.4 pounds per foot is 64,000 pounds in 1000 feet—you know that? A. Oh, yes.

Q. And you get 9.3 pounds off of it— A. If the corrosion were uniform, it would be nine sixty-four thousandths of the total weight of the pipe. No, wait a minute. You say it is 6.4 pounds per foot and 1000 feet?

Q. Yes. A. That would be 6400—it would be 9/6400. Excuse me, it would be 9/6400.

Q. That is right. Now, do you know anything about the cost of that pipe? A. I know it is pretty good steel, and in some cases they use a steel alloy.

Q. How much a pound does that pipe run, have you any idea? A. I don't know.

Q. If I told you that it is 5 cents a pound, and you say you have lost 9.3 pounds in 1000 feet in taking off this one or two or three thousandths of a foot, that would mean that you have actually lost about 45 cents worth of pipe? A. No, that is no comparison at all.

Q. By weight it is? A. Well, that is a completely fallacious argument.

Q. Well, I am asking you for the facts, not for the argument, you know. I don't think it changes the case. A. If that was 45 cents worth of pipe you asked me, and I say no.

Q. By weight, if it is 5 cents a pound? A. You don't figure a loss, a financial loss by weight.

Q. I am asking you if that isn't about 45 cents worth of pipe? A. No.

Q. By weight, if the pipe is 5 cents a pound? A. I say it is not.

Q. All right. Now, have you got the analysis for the commercial acid that you used? A. Yes.

Q. Did you make different analyses for the different shipments? A. No. We made analyses of the crock acid before each run, you see, to be sure. We did not want to analyze each carboy, so we blended the right mixture for a run and took samples of it and analyzed it to be sure that just before the run we had the right composition, so we have those figures.

Q. You have an average? A. I have figures for each run, with the exception of two runs, and we were using the same acid, the same shipment in those runs that we used in others and the analyses were coming out so uniform that those runs were not made, the analyses by per cent inhibition of each batch was run. That was the real important factor that we had in mind.

Q. Well, now, what I want to know is the amounts of copper, lead and iron in your acids? A. Which run do you want?

Q. If they are different list them for me, if you will? A. Well, run 1-A the iron was 9.3 parts per million, the lead 1.3 and the copper .21. In run 1-AA, 4 parts per million of iron, 1.1 of lead, and .02 of copper. In run 2-A, 9.3 of iron, .9 of lead, .04 of copper. In run 2-C, 6.5 parts per million of iron, .3 of a part per million of lead, .11 parts per million of copper. Run 1-B, 11.2 of iron, .9 of lead, .16 of copper. Run 2-B, 14 parts per million of iron, .4 of lead, and .09 of copper. Run 1-M, 6.6 of iron, .15 of lead and .09 of copper. 1-N, 16.7 of iron, .4 of lead, .09 copper. 2-M, 11.2 of iron, .2 of lead, .16 of copper. 2-N, 8.7 of iron, .5 of lead, and .16 of copper.

The average for the copper is about fifteen hundredths of a part per million. The average for the lead, very roughly around half a part to one part per million, and iron is around maybe eight parts per million. I haven't averaged them. I have given you a general picture and there was very little deviation.

Q. That is about one-tenth as much copper as reported in PX-161 for the acid taken from the defendant's storage tanks and about one-twentieth as much lead and about one-fourth as much iron? A. Well, now, what exhibit are you referring to?

Q. PX-161. It is my copy of Dr. Bartell's work? A. This shows .98 in Exhibit PX-161, .98 parts per million of copper and the highest figure we got was .21 in any of these commercial acids.

Q. And the highest figure Dr. Bartell reported was 1.5? A. Yes, and the lead is about ten times or fifteen times as much lead as we had and copper is about five times or so of the acid that we had here.

Q. Now, do you have any knowledge of the amounts of copper and lead and iron that are ordinarily found in hydrochloric acid, commercial raw hydrochloric acid?

Mr. Owen: May I call attention to this fact, Mr. Lyon, that this analysis is of the concentrated acid, not of the 15 per cent?

Mr. Lyon: That is right, the numbers should be divided in half. A. You should divide it half.

Q. I think you did. A. No, I didn't. The other is 15 per cent, so yours is different. The difference would not be as great. If your concentrated is .98 parts per million of copper, and if you dilute it it would come down half.

The Court: That is commercial? A. That is commercial.

Mr. Lyon: The commercial, the maximum is about 30 so it would reduce it to 15 per cent, to put in equal parts of water.

The Court: The commercial is about 70 per cent water and 30 per cent acid?

Mr. Lyon: That is right.

The Court: And when you talk about 15 per cent you just put half water to this commercial?

Mr. Lyon: That is right.

Mr. Lyon: Now, I started to ask you, have you any knowledge as to how much lead, copper and iron is usually

found in different raw commercial hydrochloric acids? A. No, I do not have such knowledge, but from the figures that I have seen from time to time on inhibition value of various commercial acids why I would say that the copper and lead content must be very low. I have seen many figures on inhibition of commercial acid.

Q. Are you familiar with the standards of the American Society for Testing Materials? A. Oh, I am not familiar on that particular subject. I know in general about them.

Q. Have you ever looked at them to see what tolerances on copper, lead and iron there are in commercial hydrochloric acid? A. I have not.

Q. Do you know whether the amount reported in PX-161 is an unusually high, unusually low or an average amount? A. I don't know.

Q. How did you come to get an acid with only a fraction of the amounts that are found in the defendant's storage samples, as reported in PX— A. (Interrupting): I can't answer that question at all.

Q. Who ordered the acid for you? A. I ordered the acid through our regular purchasing agent, I told him that I wanted regular commercial acid. The only thing that happened, we must have purchased 100 or 150 carboys—one batch of acid when we mixed it up and measured its inhibition, it was 30 per cent. That was just the commercial diluted, and we found that they had slipped in—during this last year the Grasselli Company is starting to make a special inhibited hydrochloric acid for some government work, and by mistake they had slipped in one of those carboys, and we dumped it into the tank, and noticing that the color of the tank was darker than usual, we ran the inhibition immediately before running the test, and found that it was 30 per cent. But every other carboy we bought, we put through this test, we did not throw out any of them.

Q. Well, now, do you have this handbook with you, of the testing society? A. I do not. The A. S. T. M. publishes—well, I have got a whole side of my library covered

with their publications. I do not know which one you are referring to.

Q. I want to ask you now a few questions about these tests that you made on oil? A. All right.

Q. Your tests show that the rate of corrosion of any of these acids will be reduced if the surface is oily, or has been oiled, covered with oil, isn't that correct? A. That is correct.

Q. Can you give us any idea as to the order of magnitude there of reduction in corrosiveness? A. The figures that I gave you were, when we immersed the same article, put it over again into our acid, it was 12.1 per cent, in straight acids, 15 per cent commercial acid. When we put 2 per cent of oil in with the acid, and shook it up, and then put our sepecimen in, the inhibition was 20.4 per cent. Can you interpret those results as to what will be the effect in the acidizing of a well, or running or pumping oil down a well ahead of the acid? A. Well, it would be indicative that you would get some inhibition due to the oil.

Q. You could not say from your tests how much that would be? A. I think in this particular case, in this oil from the Zahn well, which seemed to be very high in sulphur, according to the odor of it, at least, it had a much stronger odor than any of the Michigan crudes that I have ever smelled—with that you would get something like 10 to 20 per cent inhibition, and you would get that on top of the inhibition due to the metals.

Q. Now, of course, that effect of—that measurement that you got there is based on this burnished tubing of yours, that had been especially prepared and cleaned for the test; that is true, isn't it? A. Well, the metal was bright. I wouldn't say it was burnished.

Q. You run this wire on a machine, didn't you? A. It was not a real smooth surface finish. It was fairly smooth. I mean, you wouldn't tear your hand or anything. But there were plenty of points of contact on that surface that you might say could have held oil onto it.

Q. Do you think that you would fairly say that that

was true in a comparable sense to the inside of a piece of tubing that is ordinarily found in an oil well? A. Well, many oils show no inhibition, and this particular one—

Q. I was asking about the tubing. Do you think your cleaning up that tubing and scouring the tubing and treating it with the acid might have some little effect? A. It might have some little effect, but I don't think it would be appreciable.

Q. What is the condition of ordinary tubing as you find it out in an oil well, or at an oil well? A. Well, the stations I have seen, as I say, had a little rust and a little dark colored rust, and usually some oily film possibly on it.

Q. We are talking about the inside. A. Yes. I think that is the usual condition of it. Dark colored. In some cases it is fairly clean and in other cases it isn't so clean.

Q. As I understand, you don't have the weight of that tubing that you employed, per foot, in your tests? A. Yes; I gave you the figure, 2.4 pounds per foot.

Q. Is that the weight? A. Yes. I gave you that.

Q. Well, have you given me the percentage loss in weight that is represented by the figures that you have expressed in grams per hundred feet of tubing? A. Well, if it is 2.4 pounds per foot of tubing, and the tubing is 100 feet long, it is about 240 or 250 pounds. And dissolving two pounds or a little more off it, that is two pounds out of 240 or 250, that is a little less than one per cent.

Q. Well, as a matter of fact no experiment of yours consumed as must as one per cent of the tubing, did it? A. Well, let's see. We came awfully close on one of the tests, to one per cent. Very close. I think it was 1043 grams or 1050, something like that. And that is practically one per cent.

Q. That is the highest? A. That was the highest. And the lowest was down about eight or nine tenths of a per cent.

Q. Have you given us the average rate of penetration

of the tubing by the commercial acid, the raw commercial acid? A. You mean how many inches it ate back into the—

Q. (Interposing): Well, how much of a fraction of an inch it ate back. I figured it out here as .00039 inches per hour. You think that is right? A. If you figure down to an hour, you might get a low number like that.

Mr. Owen: Better figure it, Doctor. A. Well, I will.

Mr. Lyon: .00039 is what we figured from your data. A. Well, I have to get the inside diameter of this tubing. I don't recall it offhand. And the specific gravity of steel, and so forth. I don't have those figures here.

Mr. Owen: Perhaps Mr. Lyon can give them to you. A. The inside diameter of inch and a quarter tubing. Have you got it?

Q. (By Mr. Lyon): The outside diameter is 1.66 and the inside is 1.38. A. And the specific gravity of steel?

Mr. Lyon: 7.8. A. The figure I get for the thickness of iron dissolved is about .00044.

Q. My associates here seem to take considerable exception to your statement that an ordinary chemist could have calculated the effect of this lead in the tank and they want me to ask you some more about that. A. I have indicated, in discussing Menaul—you asked me if there was any merit of invention in the thing, and I said that there was some possibly.

Mr. Lyon: My associates are pacified by the witness's last statement that he acknowledges that Mr. Menaul made something of a discovery. A. I think there was some element in there. I wouldn't say that it was real obvious. I think that there was some little element to protect the storage tank there.

Q. Now, coming back to the tank and the source of this copper, do you think any of the copper comes from the walls of the tank? A. I believe so.

Q. Ordinary steel would have copper in it? A. Some little copper in it.

Q. When you get down to talking about one or two parts per million, it has got to be pretty pure not to have

it? A. These ordinary steel tanks are not usually used to carry hydrochloric acid in.

Q. Don't you believe if anyone attempted to transport commercial hydrochloric acid out to a well in a steel tank, by the time they got there in an ordinary case they would have as many as two parts of copper per million in the acid? A. I don't know. They might have. It would depend on what kind of steel they use, and the rate of attack, which I can't tell you.

Q. How much copper does ordinary steel have, the kind of steel you make an oil tank out of? A. As I recall, that is quite variable. It may run a couple hundredths of a per cent or maybe run higher.

Q. Now, I think you said there was how much copper in the lead of this lead plate that you bought or used? A. I have an analysis of that lead, if you want the exact percentage of copper?

Q. Yes, I do. A. Around five hundredths or six hundredths.

Q. You better look at it and be sure of that? A. Mr. Lightfoot, do I have that sheet up here? I don't know that I have. It met the specifications of chemical sheet lead, I know that. This analysis shows .063 per cent copper.

Q. What do you mean, it met the specifications? A. From the A. S. T. M. We received a letter from Mr. Rebbeck or someone, the information that this was chemical lead, and he gave us the specifications, and we looked it up in this A. S. T. M. book of specifications for lead and for chemical lead the copper maximum is .08 and the minimum is .04, and this sample was .063, so it came in about the middle. The rest of the elements are listed here.

Q. Iron and lead and copper? A. Iron, lead, copper; they are not listed, no. The metals listed here are bismuth, maximum of .005 per cent. Iron, a maximum of .002 per cent. Zinc, a maximum of .001 per cent. Arsenic, antimony and tin together, a maximum of .002 per cent. Copper, I gave you the upper and lower limit. Silver—

Q. That copper is .08 per cent? A. Yes. And silver,

a minimum of .002 per cent, and a maximum of .020 per cent. Now, you asked me a question as to whether there were any specifications on leads that were commercially available that had no copper in them, and here is one that is called corroding lead, and I am quite sure that is very low cost. I am sure that is used to make white lead, and that white lead sells at a very low price.

Q. Is that the kind of lead you would have in this sheet that you put in the tank, or is that a powder? A. I think you can get lead in any form you want. The copper maximum is .0015 per cent, for this corroding lead. That is where I got the idea it was a commercial lead that was very low in copper.

Q. What is meant by chemical lead? Does that mean the kind of lead where you use it for chemical operations, where they want a relatively pure lead? A. I don't know exactly. I think probably it is but I am not sure.

Mr. Allen Owen: May I call the witness' attention to the fact that there is a note at the bottom of the page describing those leads. A. Oh, yes. Corroding lead is a designation that has been used for many years in the trade to describe lead which has been refined to a high degree of purity. Chemical lead has been used for many years and it is a de-silverized lead. Acid lead is made by adding copper to fully refined lead.

Q. And you are willing to accept the view that the kind of lead plate that you employed in your operation did not constitute a deliberate attempt to add copper to the acid? A. I don't want to go into motives. I couldn't tell you motives. I don't know. The fellows looked pretty honest to me.

Q. If you had been interested in this system five or six years ago and hadn't known that this copper had any effect at all, you would have purchased this same kind of lead, would you not? A. I don't know. I don't know.

Q. Were you the one that discovered that this lead—this copper in the lead was the bad actor, or the infringer in this operation, or did somebody tell you about it before

you went to work on it? A. I had heard it, as I said before, I had heard almost from the time of the Grebe-Sanford invention that copper was an inhibitor for hydrochloric acid, and when I saw these analyses that Dr. Bartell made, that was the one possibility.

Q. You recognized it as a possibility then. You had to go to work on it to check it and see? A. Well, if I knew copper was an inhibitor and it was present in this acid, why the logical thing was that it was an inhibitor in the acid.

Q. In what form was copper used there by Grebe and Sanford as an inhibitor? A. I couldn't tell you that. I said my recollection was very vague; that I knew copper was an inhibitor and knew that general statement, but I couldn't tell you the amounts or form or anything else. I knew copper was an inhibitor and I can produce documents to show that.

Q. Let us have them. A. I am going to do that. I can't do it right now, sir.

The Court: Does it show what copper does? A. It plates out and the hydrogen that is plated out with the copper is held on tight by the few molecules of copper that are plated out.

The Court: Is there any kind of inhibition, except that kind that puts something on the iron to prevent the hydrochloric acid from eating it? Is there any other kind of inhibition? A. I think when you get down to the fundamentals there is no other kind.

The Court: We had some talk earlier here about two kinds of inhibition, one of the kind I have described, and the other one which in some way pulled the teeth out of the acid, so that it could not bite, but I have not heard in all of the testimony any description of that, or any formula for it.

Mr. Lyon: I tried to get into that a little while ago, but I did not get very far. A. It is my belief that all of them act by forming some film. I believe that the thing that stops corrosion is the film, a film of some kind. It may

be started by some electrical action, as they claim practically happens in their truck tank, but—

The Court: Well, I will take that until somebody else claims to the contrary to know about it. Let it go at that.

Mr. Lyon: Well, now, it looks from your figures as if the copper was accumulating in the acid in the tank, in the Menaul operation, faster than the lead was, in the proportion that you have found the copper and lead. Did you notice that? A. That is correct.

Q. Can you explain that? A. Yes, because the lead in corroding forms lead chloride, which is relatively slightly soluble, some of that dissolves in the acid; but the copper when it dissolves, it forms a very soluble compound, and it goes into solution; but to get the lead which has corroded from the sheet of lead into the solution, you have to use a tremendous amount of agitation, and that is a film of lead chloride over the surface, and that is why the copper is in greater proportion than the lead.

Q. Is your statement that the copper plates out based on an actual proven experiment, or is that your opinion of it? A. That is my opinion, and the opinion is based upon the fact that if you put this copper in—without copper in solution, you have your hydrogen plating out on the cathodic parts—when you put your copper in your hydrogen goes out and forms this film, and the only way that you can get that polarized film of hydrogen is to have your surface altered, and the only way it can be altered is by plating out the metal in solution.

Q. It can't both be plated out and stay in this solution in the soluble form that you have described here. Which does it tend to do? A. It dissolves from the lead and plates out on the iron, a small amount of the copper plates out on the iron.

Q. Have you ever actually found that on iron? A. No. I say, there is just a molecule here, and a molecule there, but if you have got to explain the altering of that surface, the formation of a polarized film on there, the only way that you can explain it is by having a minute

amount of copper plating out of the solution on to those parts.

Q. Doesn't the lead tend to affect the surface as described in the Menaul patent? A. Yes, with the lead plating out, you get that lower voltage helping to plate out the copper on to the iron, but it is not very great.

Q. Is that tending to plate out the copper—is the lead helping to plate out the copper, or the copper helping to plate out the lead? A. Oh, no. I would say the lead has some very slight effect in helping to plate out both copper and lead, but it isn't very much, it hasn't enough voltage. There isn't enough voltage to plate a continuous film of either one of them.

Q. Well, isn't it true that according to your figures there is 16 times as much copper accumulated in the acid as there is lead on the basis of the portion of copper that you say existed in the lead? A. I would have to do a lot of calculating to answer that question. I will state right here the amount of copper increase in the solution is considerably greater than the lead that goes into solution, several times, probably. I have stated some of that copper undoubtedly comes from the tank. Just how much, I don't know.

Q. As I understand your statement, you were the one that first suggested to the Dow Company that the thing to emphasize in this case was this presence and action of 3 parts per million of copper, is that correct? A. No, that isn't right.

Q. I said "I understood." I ask you for the fact. Were you the first one to develop this theory? A. No, I don't believe so.

Q. Who told it to you first? A. I don't recall. I have had many talks with Mr. Chamberlain and Mr. Rebbeck and the thing evolved.

Q. Did you have this theory when you started to work on the case ? A. I had talked to these men even before we started to work. It wasn't a gradual thing that they came up to me one day and said: "Here is a bill of goods. You

do that." You talked generally about the thing, and when we got to a certain point we began to do the work.

Q. You say "gradually evolved." What evolved? A. Discussion. When we saw Dr. Bartell's figures, they came up in the discussion. I don't know who had the idea. I had heard discussed this copper is an inhibitor.

Q. This theory copper is an inhibitor is an evolution of discussion and development of a proposition as you went along in these experiments, is that right? A. The first time I ever heard of the Menaul process was in a discussion I had—I don't recall with whom but someone in Dowell, and it was the same conclusion we have now reached, that the Menaul patent was a front, a method of getting inhibitor into the acid, in order to practice the Grebe-Sanford patent, and I have never changed that idea since then while we have gone along.

The Court: Did the lead do it? A. I don't think we had analyses to prove it. Possibly the lead did, or something in the lead sheet. We couldn't tell but we felt they were dumping in inhibitor to help the thing out. That is the thought that came out in everyone's mind. I never have heard that thought resulting in proof; it was a developed process.

The Witness: Did you want this publication on copper inhibitors? You asked me for that.

Mr. Lyon: Yes. Whatever you have got. A. Here is one reference that they dug up for me here some place. Should I read it?

Q. If you can. What is the reference? A. It is from the Automotive Industries, December 5, 1918. And reading the quotation—"Tin and copper salts are representative of the inorganic type of semi-collodial inhibitors." And the article is on the chemistry of pickling baths, which is a —in which inhibitors or the development of inhibitors was quite an important thing.

Q. Would you say that that article represented the regular view prior to Menaul's invention? Wasn't there a great deal of literature in connection with electro-chemistry

to the effect that copper increased corrosion? A. I wouldn't admit that. I don't think that is the case. I can't give you any definite proof as to what the general knowledge was or anything else, but when people publish material like that, why, it indicates that somebody found that copper was a pretty good inhibitor.

Q. Does that say for hydrochloric acid? A. I think it said pickling solutions, and I don't know what acid—usually sulphuric acid, but usually in the inhibitor art if they are fairly good for sulphuric they are pretty good for hydrochloric, as a rule. There is no exact correlation. I think I have lost my place.

Q. Is that the best article that these folks can— A. (Interposing): I asked Mr. Rebbeck here a minute ago, and he just gave me the one. In my general reading on the subject of electro-chemistry and inhibition, why, I am quite sure I ran across the mention, and I can't say how many times, but it is a typical illustration of what is in the literature.

Q. Now, you tell me what just adding copper indiscriminately as copper to one of these baths would do to a steel tank, or steel car? A. Well, I would say that there undoubtedly is some optimum composition or concentration of copper for each different acid solution and so forth that gives you the best results, and if you exceed that you might get a continuous, complete coating of copper deposit, or it might be loose, and it might cause detrimental effects. I will grant to you that if you exceed a certain concentration of copper in solution that you probably would get some detrimental effects and it would not be an inhibitor.

Q. Well, that is the point. And do you know of anything in the art that taught, prior to your work on this case, that these minute amounts of copper which you are now talking about down to not more than five parts per million had this effect that you have shown here? A. Well, it is true for every inhibitor, that if you add an increasing amount of inhibitor you get generally increasing inhibition, and there are some of them you go up over a

hump, and then down. But to try to find that hump is hardly an invention.

Q. Well, I am not asking you that. I am asking you if there is any public disclosures of the fact that we have here in this case? A. Of adding it to hydrochloric acid?

Q. Yes, prior to your work on this case? A. I don't think so. But the fact that copper was used to inhibit acids, it is just like telling somebody to put some salt in some food. Well, you put different amounts of salt in different kinds of food for different people. You put the right amount in to make it taste right. So you put the right amount of inhibitor in your hydrochloric acid to make it do the job.

Q. Would you have known from this manual that you have just had read here how much copper to put in to do the job? A. No, but I would have turned it over to a very inexperienced individual that would have tried it, knowing that it was an inhibitor, having been told that it was an inhibitor, he would try the different concentrations and find the correct concentration.

Q. Did you every talk with Mr. Rebbeck or Dr. Grebe, or anyone in the Dow organization, as to what he had in mind in the statement in the patent in suit, No. 1,877,504, commencing at line 75, on page 1, where he calls for adding a small amount of a substance capable of inhibiting attack of the acid upon metal surfaces, e. g. of iron or steel, copper, etc.? A. I would like to read the language of the patent. The statement is, (reading): "To the acid we add a small amount of a substance capable of inhibiting attack of the acid upon metal surfaces, e. g. of iron or steel, copper, etc., with which it comes in contact."

In other words, you put some material, a small—a relatively small amount into an acid, that will slow up the rate of attack of that acid upon the metal surfaces that it comes in contact with. Now, in an oil well, that is usually steel.

Q. Well, now, in the Menaul system, is there anything added to the acid that inhibits its attack upon a metal surface, if that metal surface is copper? A. I don't know. I haven't made any tests.

Q. You know, don't you, that the presence of this copper is due to some action of the acid, in the Menaul process? Didn't you tell us that some of this copper could have come from bronze or a copper pump or fitting in the system? A. Yes.

Q. That would be because the acid would attack the copper, isn't that true? A. It would attack copper alloys. It might not necessarily mean that it would attack copper. I don't think the patent implied that it would inhibit the attack on all metals, just the metals that it encountered in the well. For example, if the well was iron or steel, it inhibited iron or steel.

The Court: And if it was copper, it would too. A. Well, if there was copper in the well, it would, if you had an inhibitor that would inhibit it if it was attacking copper, yes.

Q. The claims in this patent are not limited to steel or iron but to include acid upon metals, you have noticed that, haven't you? A. But if you have a well with all steel equipment, then the patent teaches, in my opinion, that you add an inhibitor that inhibits the action of acid on the steel. If you have a well that has a different metal in it to contact the acid, then you add an inhibitor to inhibit the action on the other metal, copper, for instance. If you have a mixture you try to get an inhibitor that will do a good job on either one of them.

Q. The point is nothing in the Menaul system includes any adding to the acid of a substance capable of inhibiting the attack of acid upon copper. You agree to that, do you? A. I do not agree to that, because I cannot answer the question. I cannot tell you whether the lead and copper in solution in the Menaul acid will inhibit the attack on pure copper. If you take raw acid and you take a brass valve or some alloy like that, I believe you would get some copper going into solution. I don't know what would happen after that. I do not know whether it would attack the brass or the bronze or pure copper.

The Court: I am wondering if I get into this dilemma,

that if I did not put in anything—if they would both be there, copper and iron, and I didn't put anything in, to inhibit its attacking the copper, then it would attack the copper and make an inhibitor for the iron, and I would be in a mess. Supposing it has got copper and iron and I use pure acid, am I liable, is it chemically possible here that that acid would get busy in the copper and get enough of that little bit of copper out so that it will make an inhibitor down in there against the iron? A. I would say that if the acid contained sufficient copper, no matter where it came from, sufficient lead no matter where it came from, sufficient inhibitor of any kind no matter where it came from, except from the Menaul practice of commercial acid, in other words, if those things were added extraneous, I mean it went into the well, the top of the well, if you took and pumped that acid through a two inch copper pipe one hundred feet long, in order to get copper into it before it goes into the well, I would say that would inhibit the inhibiting acid going into the well.

The Court: It goes right down. A. Supposing down at the bottom, if that is normal construction in an oil well, which I doubt very much—I am not enough of an oil well man to tell you—if it is normal construction to use brass parts at the bottom of the well—I know it is not all the way up between the top and the bottom—if that is normal construction, you get some inhibition and I would say that probably is perfectly all right, because your acid has gone into the well uninhibited.

The Court: Now, you are answering a legal question. What I was really starting to ask you was the chemical question as to whether or not if there was copper down at the bottom of that well whether you wouldn't make the acid —whether you wouldn't get enough of that copper off so that it would make a practical inhibitor? A. It would depend on how much contact it got with that metal, but the acid in going by that would be leaving the metal sysem of the well and going out into the formation so you would have no effect.

The Court: Can you tell me how much the surface of the copper would bear to the amount of the surface of the iron to do the trick? A. I can't tell you that. I think it would have to be a fairly appreciable surface.

Mr. Lyon: Will you tell us what happened in the Frasch patent? A. I have not looked at it recently.

Q. He says there he can use a lead-lined tube in his well to put his acid in. If he used a lead-lined tube, what would happen? A. The acid would start into the well uninhibited. By the time it got to the bottom it would probably be somewhat inhibited, but again the inhibition would be completed when it got to the bottom of the well.

Q. Well, now, you have described the fact that this copper is in the lead. It is there as the metal copper in the lead, isn't it? A. That is right.

Q. When this plate is put into the tank. Now, it gets into the acid by being dissolved and forming copper chloride, doesn't it? A. Yes.

Q. Isn't that the way acid corrodes a metal surface, by dissolving material off of the metal surface to form a chloride? A. Oh, yes; that is the usual way.

Q. Then, as a matter of fact, all the copper that you found in this acid got there because of the process corresponding to corrosion, that is, dissolving the metal off of a surface? A. Off the lead or out of the steel tank, or in some way it got in there, and in a truck tank there are usually brass valves or some bronze equipment.

Q. Now, you said a while ago that copper is an inhibitor for sulphuric acid. Did you mean to say that? A. I say that it is apparently an inhibitor for solutions as reported in this article. I said in general inhibitors that work in one acid—that is, sulphuric acid, are usually fairly good in sulphuric and hydrochloric. They don't necessarily have to be good in both.

Q. What about copper? A. I don't know in sulphuric acid.

Q. You don't know whether copper is an inhibitor for sulphuric acid? A. I don't know.

Q. You read this article and it doesn't tell you what acid the copper is an inhibitor for, and you don't know whether it is an inhibitor for sulphuric. Now, did you know anything about whether copper was an inhibitor for hydrochloric acid before you started on this case? A. I very definitely did. That article talks about pickling. Pickling itself, done with several kinds of acid, usually sulphuric or hydrochloric. When they say it is an inhibitor I take their word it is an inhibitor. If I read that article in 1918 (I may have seen it—I don't believe I did) it made a mental impression on my mind copper was an inhibitor for non-oxidizing acids.

Q. You made a mental note of this article this afternoon but you don't know now whether it is an inhibitor for sulphuric acid or not. A. I will say from what I read (I can't say from my own experience—I haven't made any tests) but from my reading and understanding it was an inhibitor for the acids, hydrochloric and sulphuric acid used in the pickling art.

The Court: From reading that article, so far as your getting any information, copper would be an inhibitant for hydrochloric, it would be the same for copper as it would be an inhibitor for sulphuric. A. Yes, from the article. But by my own experience I have not run any tests nor could I possibly tell from my readings, and so forth. I would come to the conclusion not from any tests I have made. I have not made any tests for sulphuric acid.

Q. You said copper was an inhibitor because you read one article. Now, you have read this article this afternoon. Do you know whether copper is an inhibitor for hydrochloric—for sulphuric acid? A. There are different ways of reading things. You read it, get a picture, draw a conclusion that is a correct statement. Sometimes you don't perform the work yourself to verify it. You couldn't. So, part of my experience is based upon what I have read, picking up on reading of other people's work.

The Court: What I understand from your remarks is if teaching prior to your experiments that copper was an

inhibitant for hydrochloric acid, why doesn't it teach today that copper is an inhibitant for hydrochloric acid and for sulphuric acid? A. Well, I think it does.

Mr. Lyon: And you think you know copper is an inhibitant for sulphuric acid? A. I will say that there is probably some concentration, sulphur salt, salt compounds, that will inhibit sulphuric acid to some degree.

Q. According to your statement there was one part of copper to 1600 parts of lead, as I understood one of your previous statements, that is correct isn't it? A. One part of copper to 1600 of lead is correct.

Q. And in these samples of the acid that you analyzed from the Menaul tank after the acid had been in there for six or seven hours, you found one part of copper for 100 parts of lead, didn't you? A. I think something like that.

Q. Now, you have suggested that the reason for that copper increasing 16 fold is that lead chloride wasn't as soluble as the copper chloride, is that correct? A. I assume that we would be correct that the ratio that you get of copper to lead in the solution cannot be figured from the analysis of a sheet of lead; that you get a higher proportion of copper going into solution. I did not say all the copper came from the lead sheet, but if you would take a piece of this lead sheet and dissolve it, convert copper to copper chloride, lead to lead chloride, and then dissolve that thoroughly in the acid solution, you would have a ratio of 1 part of copper to 1600 of lead. That is correct. Now, if you take four times as much of that sheet of lead, or three times as much, or in some number like that, and convert that by reaction with hydrochloric acid into lead chloride and copper chloride and then contact that with solution, the copper will go into solution and in my opinion the lead chloride is much more difficultly soluble, and you will have samples of lead chloride floating around which we observed. Now, that would produce a ratio of copper in solution instead of 1 to 1600 about 1 to 400. I don't know what that number is. It might be 1 to 200. Then there is some copper that comes from the steel tank, and that I don't know how much it is either.

Q. Well, now, how many parts per million of lead chloride did you find in solution in the analysis of the acids from the Menaul tank, after the six or seven— A. (Interrupting): You mean Dr. Bartell's figures, or of the figures that I made in this laboratory test?

Q. In your test you found one part of copper to one hundred parts of lead, did you not? A. We got about three or four parts per million of copper to 250 to 400 parts per million of lead chloride in solution.

Q. What is the solubility of lead chloride in hydrochloric acid 15 per cent? A. I don't know.

Q. Don't you know that it was only a small part of the lead chloride that would dissolve in the acid? A. I assume so, yes. I did not say it was saturated.

Q. Then there is plenty of room in that solution, as far as you know, for more lead chloride? A. Yes, but if you take lead chloride and you try to dissolve lead chloride in hydrochloric acid,—we have made many of these synthetic runs—in making the synthetic mixture for the running of laboratory tests, we have had to shake them for a considerable length of time, and use special pulverizing methods to bring in the crystals. The rate of solution of lead chloride is very low. I didn't say that the solution was ever saturated in those tests, but the lead crystals form on the surface of the lead sheet and then break off and float in the solution towards the bottom, some sticking on the lead sheet.

Q. Can you tell us how much of the copper that you found in your analysis of the acid from the Menaul tank, was introduced into that acid, or got into that acid from the lead plate? A. I cannot tell. I would assume that it is between one and two parts per million, maybe two.

Q. Well, can you tell? A. I cannot tell, no, because it is impossible to separate it.

Q. Did you analyze the walls of the tank? A. We analyzed the steel walls.

Q. Do you know whether it had any copper in it? A. It had copper in it, yes.

Q. Do you know in what order? A. I don't know. I think it was around two-tenths of one per cent or so.

Q. Did you analyze the oil well tubing? A. We analyzed that.

Q. Did you find any copper in that? A. As I recall, we found about three hundredths of a per cent copper in it.

Q. But you don't believe you analyzed the tank? A. I don't recall that we analyzed the tank. I think we got some general figure from the man that sold the tank. We did analyze the steel that was submitted from your headquarters as steel that went into the Halliburton tanks.

Q. Did you find any copper? A. Fourteen hundredths of one per cent.

Q. Now, did you analyze the samples that you took at the bottom of the tubing for their copper or lead content? A. I analyzed those.

Q. Where is the report on that? A. We haven't got that in the report.

Q. What did they show? A. They didn't show much of anything. They showed that the copper going in and out was substantially the same.

Q. Same amount of copper? A. There was some change in some cases, but very little.

Q. Well, enough so you consider there was any change? Would the figures be enough different so that they showed a change beyond experimental error? A. Well, some of the figures in the effluent acid that were obtained when we ran the—as I recall the blank acid tests, the copper was analyzed on small samples, and we did not feel that the accuracy was any too good. I don't recall the figures. We got about one part per million in that effluent acid, and we actually took those samples and ran inhibitions to see if we could check back and see if they were inhibited due to the copper picked up from the pipe, and as I recall it the inhibitions were very low.

Q. Now, wait a minute. Let's take the commercial acid when it was run down the pipe and you analyzed the acid samples for copper? A. When the commercial acid was run down the pipe, we ran the exit samples for copper.

Q. Did you? A. In some of the tests, I don't know.

Q. And have you got the results there? A. I don't think I have them in any report here. I think they are in those notebooks some place, that I could dig out.

Q. Well, you remember what you found? A. I don't remember.

The Court: What would you expect to find? A. We expected to find that when the acid ran through the iron tubing, which contained a trace of copper, that the effluent acid would contain some small amount of copper over what the commercial acid did.

The Court: More? It would pick up? A. Surely. Because when the steel tubing is dissolved part of the copper is dissolved.

Mr. Lyon: Did you find that? A. We found that, as I recall, that some of it did dissolve.

Q. But you don't remember how much? A. I don't remember exactly.

Q. Well, now, what did you find in the case of the acid that had been in the Menaul tank for six or seven hours? What did you find out from the exit samples of that acid as to its copper content? A. I don't recall the exact figures on that. I don't think there was much of it at all.

Q. You mean the acid coming out, the exit acid, had just about as much copper in it as when it went in? A. That is my recollection.

The Court: What would you expect on that? A. That is about what I expected. There isn't much metal dissolved in the—

Q. (By Mr. Lyon interposing): Where has all this copper gone that is going to plate and protect the tubing? A. I told you it was only an atom here and an atom there. I wouldn't expect there would be much copper used up. Just a minute amount that is going to plate.

The Court: But that is the thing that is going to stop the corroding by the acid, is the coating that goes on, as I understand. A. That is true. But you take acid with a certain copper content and run it through a pipe and it

dissolves from the surface of the pipe iron, and some small amount of copper, and you have or may have that plate on certain areas of the pipe and the copper go in solution from the pipe. I just don't know how, but the effluent may not be greatly different. It may be a minute amount different.

The Court: Why don't the—if that is all this inhibitor does, is to do that spotty job of plating, why don't the acid eat the places that are not plated and make pits? A. Well, that is the part, where it is not coated with the copper, is the part that is the pure iron, and the cell—the copper over in these other parts is putting this hydrogen layer on that and prohibits that cell from acting, the iron dissolving, and the hydrogen plating.

The Court: I am talking about the spots that are not coated. A. That is what I am saying, that in order for the iron to dissolve you have to have this electro-chemical cell to function, and some of the parts of the steel that are pure iron, that are not coated with copper, the copper coats over on the impurities and builds up this hydrogen field which prohibits that little corrosion cell from functioning, and before the iron can dissolve, although it is bare, it has to be connected in a complete electrical circuit.

The Court: Well, then, over in this pure iron place you show there is where the hydrogen is? A. Over the impurities is the hydrogen layer; the pure iron is just uncovered.

The Court: Well, why doesn't the acid bite it? A. Well, the belief is that it requires this electrochemical action for the solution to occur. You have got to have a complete electrical circuit and the motion of the ions.

The Court: In order to have the iron— A. (Interposing): Dissolve.

The Court: In order to have the acid act on the iron? A. On the iron. But the quantity of copper is very little.

The Court: You just spoil that part of the battery that you start the thing going with, the impurities. A. Yes.

CROSS EXAMINATION (Continued)

Mr. Lyon: First, Your Honor, I might state that the plaintiff delivered to us two bound books, they seem to be ledger books, which I am going to ask the witness to identify for the purpose of the record; and, in addition, they delivered to us five holders of what appear to be preliminary reports, which I am also going to have him identify, so the record will be clear. The first of these books has written on the inside front cover the following:

(Reading): "Data book Menaul test, Dow vs. Halliburton, September 1, 1939, C. F. Prutton."

Mr. Lyon: Dr. Prutton, can you tell us what this book is? A. That book contains the data that were taken during the work on these tests that have been reported.

The book was marked for identification DX-190.

Mr. Lyon: Is this book in your handwriting, or are the entries in this book in your handwriting, Dr. Prutton? A. Very few of them are. Various writings in this book are signed by different individuals. For instance, the first subject, commencing on page 5, and ending on page 19, is signed "William J. Lightfoot," who was one of my assistants.

Q. I notice beginning on the first page of this book, DX-190, is an index and that this index, under the description or title "Description of Run" commences with a series listed A, B, C, D and so forth, and then in the next column is what appears to be a modified or revised listing changing the numerals of the run, and then there is a third column in which there is a second revision. Can you explain that? A. No, I can't explain that. We simply ran these runs at random and they were all mixed up. The Menaul tests, and so forth. And when we came to write, to split them up and write a report on the Menaul tests separate from the report of the crock tests, why, we changed the designations of those so that they would be more in order.

Q. Well, the reports which have been offered in evi-

dence here, Exhibits PX-184 and PX-185, present the data in somewhat different recalculated form than what appears in DX-190; that is correct, isn't it? A. Yes, I think there is a little difference.

I did not personally prepare the tables that are set forth in PX-184 and PX-185. My recollection of the way in which the written text of the reports and statements contained in PX-184 and PX-185 is that I wrote it up in longhand and had Mr. Lightfoot go over it and edit it to see if it should be corrected somewhat, and then I worked over the final draft so I would say that I probably wrote it.

As to the order of the experiments recorded in DX-190 and which of those experiments or runs are reflected in PX-184 and PX-185, might I ask Mr. Lightfoot to help me with this? He kept most of the books here, and the data, and so forth.

The Court: Would you like to have him sworn? I don't care to, but they did that before. When Dr. Bartell was here, we had his associate, and as I remember they were both sworn as witnesses.

Mr. Lyon: Perfectly all right with me. I am not interested in this witness except to get the facts before Your Honor in the quickest way.

Mr. Lyon: Now, the first run recorded in DX-190 is written up commencing at page 26 of DX-190 and continuing through to page 35, and is signed by Merrill L. Reihl and is dated 11/24/39, entitled "Run No. A." Can you tell me whether or not the results of that run were reported in PX-184 or 185? A. I don't believe they appear in any of the reports. I am not sure. That was the original set of tubing that we did not use in any subsequent runs. We found out that different lengths of tubing gave different corrosion rates and therefore we picked out two subsequent sets to run the remaining tests on. That was my recollection. That was one of the first runs.

Q. Well, how do the results of that run compare with the figures that you arrived at in your conclusions in Exhibits 184 and 185? Can you state at this time? Were they higher or lower?

Mr. Lightfoot: I believe about the same.

A. I think they are the same order of magnitude. There was not a great deal of difference. As I recall, we used a 100 foot length of tubing in the run and we got a lower amount of iron dissolved.

Q. Run A commences on page 26, and after a description of the run a suitable length, it contains record of the exact determinations. It doesn't look to me as if that run is any different from others that you made. It seems to have entirely different results. A. Well, 200 gallons of acid, practically, so that it was similar to the other runs. Can you find the others for me?

Mr. Lightfoot: May I have the reports? This contains the calculations.

A. (Witness continuing): The numbers are here but you have to do a lot of calculating to get the results, make analyses, and so on.

Q. What I am trying to get at, compare these actual measurements with other measurements in DX-190 and tell me, if you can, why you discarded the work that is represented in this one run. A. I told you my general recollection was it was in the same order of magnitude and we had no similar runs to this particular tube.

Q. Let's be sure of that. I think the tubing is described on page 25 and under the title of "Equipment" item 2, "5 lengths of 1¼ C45 API external upset tube range 1000 AC 2.40 points obtained from Oil Well Supply Company. Tubes are new and have not been used." Now, aren't those the same tubes used in subsequent runs? A. According to my recollection they are not. We bought 22 tubes, as I recall, and we used each one of them. When I say we used Set No. 1 it means a certain number sequence number test. These tubes were not used, is that correct?

Mr. Lightfoot: That is correct.

(Witness continuing): In other words, we cut up tubes to make corrosion inhibition samples. The calculation on that run was 622.9 grams of iron dissolved. Now, we had other blank runs that ran 791 grams of iron dis-

solved. This was lower than the lowest of the blanks that were reported but we had no subsequent work on those tubes, that set of tubing; some of the tubes were sawed up to make fittings and to make samples, and it was on that run that we found out that different lengths of tubing would corrode at different rates, and that there was a difference between two different lengths of tubing and therefore either following that run or about the third one—I don't recall which—it is several years ago, we came to the conclusion that we had to take Tube 13, 14, 15, 16, put them all in a row in the same order and run the same tests through that tubing, give it a good cleaning after each run and then we could get comparative results.

Mr. Owen: Doctor, was this length of this tubing, this first set of tubing, the same as the later ones? A. It was somewhat shorter. I don't recall the exact length, do you?

Mr. Wiles: With different lengths of tubing you are using the 20-foot pieces? A. Yes, a 20-foot length of tubing when we ran acid through we might have 140 grams of iron dissolved from one length in the same run, and the next length might dissolve only 120 grams. There was a difference in the tubing and we determined after the first run or two that we were going to take a definite sequence of tubing and use it in a whole series of tests so that we could figure what the raw acid did on these sheet tubes, and on the same tubes after they were cleaned on the inside we would determine what the inhibited acid would do.

We would determine what it would do on the Menaul tests and without the wire, and the results we reported are the results of those tests run upon two completely separate series of tubings, and this result, if you take that even at its face value, and assume that it was cleaned out in exactly the same way, and that we ran it exactly the same as the rest, and this was the first run we made, and the men doing this cleaning operation probably had not standardized quite as well as they did on subsequent tests, and the first test that we ran, all the data is in the book there.

We did not run any preliminary tests and throw away

the data. That is the first run we tried and the results even if we take that as a blank, 622 grams dissolved. We can use that figure to compare the inhibited acid. The answer would be we get 50 per cent inhibition. In other words, the acid is still inhibited, even if you use that other low one as a blank. We have five blanks, as I figure. Four we reported and one we took as our first preliminary run. Even if we take this low one and use it as our standard reference figure for the uninhibited acid, still this acid with the lead and copper in is 50 per cent inhibited. In other words, that dissolved in the acid with lead and copper in, the amount of iron dissolved was from 100 to as much as 300 grams. It was down there less than a half as much as even this lowest blank and of course we did not incorporate it, or rather the reason we did not incorporate it was simply because we hadn't found out yet. We thought when we started out, we ordered from the Oil Well Supply Company this tubing, and we told them—I talked to whoever took the order, the sales department, and I told them I wanted to be sure I got this tubing from one mill run in order to get uniformity, and he said he couldn't guarantee that it would be from one mill run, but he was quite sure the tubes he would send us was from one run of the mill.

They buy a large amount of tubes and we thought if we got them the same we could more closely duplicate the tests we were making, and then this run, in this run we found that we got a difference between different lengths of tubing of about 20 per cent in the rate of attack of the acid, and for that reason we came back to the system figuring that we had to use the same tube and the same order and run the tests through that same tubing system.

Then to check on that we took an entirely different tubing system and run our tests. This first tubing system, in some of our preliminary work we cut some of those tubes to make elbows and to make small samples, and those tubes, I don't know whether they end, any of them ended up in the final lengths of tubing or not.

Mr. Lyon: Now, this run A commences at page 26 in

DX-190, and I would like to just have the court understand what is in DX-190 before the recording of that first run. I am correct, am I not, that following the index which covers pages 1 to 3, the next entry commences on page 5, and continues to page 19, and is signed on September 11, 1939, by William J. Lightfoot, and is entitled, "Copy of Dr. Bartell's report, dated January 20, 1939." A. That is correct.

Q. That report, before you undertook this work, you had Dr. Bartell's entire methods of analyses, the results of his analyses, in connection with iron, copper and lead, entered in your book to start with? A. I don't recall whether that was entered or not. I think there was just a copy of his report.

Q. Will you just take a look at it? (handing Exhibit DX-190 to the witness) A. As I recall, we obtained through Mr. Chamberlain one or two of Dr. Bartell's original reports, I mean, the preliminary work that he had done. In this material copied in here, it is mainly the methods for determining iron, copper and lead in minute amounts from acid solutions that I believe or understand that Dr. Bartell got through Dr. Willard, the analytical man at the University of Michigan, and which he had used, and we wanted to use the same methods. As I recall, and you might check me on this, Mr. Lightfoot, the figures that are reported here were some preliminary figures that were taken out of these very preliminary reports of Dr. Bartell, and the method for copper that is given here I think was replaced by another method that was more accurate.

Mr. Lightfoot: That is right.

A. We had trouble in getting very good checks, determinations, as I recall, using this particular method on our particular samples.

Our samples were different than Dr. Bartell's, in that there was a considerable amount of iron present, more so than in the defendant's truck samples. If you will remember the analysis, the average analysis reported by Dr. Bartell was some 400 parts per million of iron; and in the

samples we had, the iron was up around 1300, and even higher. In other words, the acid that we made in our Menaul tank had a considerably greater amount of iron, and, therefore, there was a possibility of the iron interfering to a greater degree in the analysis, and we found that we could not get extremely accurate checks with this method. That was subsequently replaced by another method of copper analysis which is shown in the report. The method of copper analysis that we used on all of the determinations is shown in our report, and I am not sure if it is in this book, or not.

Q. Well, does that first entry in DX-190, particularly insofar as it is directed to the determination of minute amounts of copper, refresh your recollection on the point which I asked about yesterday as to whether or not when this work was presented to you, or you were called upon to do this work, you received the suggestion from others that what they were interested in was establishing the effect of these minute amounts of copper? A. Well, I have told you that I had contact with this case and knew of this Halliburton procedure, and so forth, before Dr. Bartell was connected with this case, and, therefore, I am very sure that he did not tell me about the copper. I knew that copper was an inhibitor, had had general knowledge. I had seen—it is difficult for me to figure out just where I first got the information—as I recall some five or six years ago. I started to see analyses of the Halliburton acid that were run in the Dow plant, and the discussions that were had as to the validity of the method and as to how they obtained protection or inhibition, which these samples always showed. And I can't tell you exactly when I first found out that copper was present in the Menaul or the Halliburton acid samples. But I don't believe I obtained that first from Dr. Bartell. I am sure of that. But it is difficult for me to remember back.

Q. Well, you are quite sure, are you not, that before the samples were obtained from these four Michigan wells which have been reported in evidence here that the Dow

Company had obtained many samples of Halliburton acids and had analyzed the same and studied the same and you were in on some of those discussions? A. I had seen some of the tables of results of the analyses of some of the acids, and the inhibitions that had been run upon them, and I think it was probably from some of that work that I got definite information that copper was present. I think so.

Q. When was that? Have you any way of telling us when the idea first presented itself that there were minute amounts of copper in those test acids and that that should be studied to see if they were giving the inhibiting effect? A. It really is—there are so many little discussions and little mentions made of the thing, and with so many different people, that I couldn't put my finger on it. It was at least five years ago, I believe, and Dr. Bartell, I think, has been associated with the work only about two.

Q. All right. Now, just to continue with the contents of Exhibit 190, following the entry of Dr. Bartell's report which concludes on page 19, then we have on pages 20 through 21 some analytical work for determining the carbon in steel samples. A. Well, I don't know. We received, through Mr. Conner, samples of the steel which was supposed to represent the type of steel used by Halliburton in making up their truck tanks, and I turned them over to Mr. Reihl to analyze and told him I particularly wanted copper determined in them, and he went through, as you do in steel analyses, and just ran everything. He ran carbon and I think silicon and some of the other elements.

Q. The entries of those analyses cover through to the end of page 23 of DX-190, that is correct? A. I believe so.

Q. Now, on pages 24 and 25, under date of October 30, 1939, you have an entry of comparative runs to determine the corrosiveness of commercial hydrochloric acid that you purchased from the Penn Salt Manufacturing Company and the Grasselli Chemical Company; is that correct? A. I don't even recall that we had any acid from Pennsylvania Salt.

Q. Just examine that entry. A. I don't remember that. Did we buy the acid?

Mr. Lightfoot: No.

A. Where did we get it?

Mr. Lightfoot: We asked for samples.

A. We got the sample from Pennsylvania Salt Company of the acid, and samples from Grasselli and ran comparative corrosion tests and recorded them.

As to why we selected the Grasselli acid instead of the Pennsylvania Salt Company acid, I recall they were about the same, and we just took the Grasselli because it was in Cleveland and we could get the acid delivered immediately and without any trouble and we could return the carboys, and there was a lot more convenience. I don't recall why we got the Pennsylvania Salt unless somebody suggested it to me. Somebody must have suggested it to me, because I didn't definitely recall that.

Q. The next entry in DX-190 commences on page 36, entitled "Run No. B" dated December 16, 1939, and after the description of Run B and the entry of the data there is a table on pages 42 and 43 of the results. Those results were not carried forward or used in Exhibits 184 or 185. Can you tell us why? A. I cannot tell you why. The comments I have here, there was not enough data taken in the tank samples to permit making calculations.

Mr. Lyon: Look at the data and see if you can confirm that statement. A. This test was a peculiar test that I described to the court in my direct testimony, in which we tried to run the acid through this Menaul tank so fast—

Mr. Lyon (interrupting): No.

(Witness continuing): I am telling what Mr. Lightfoot tells me. Ran it through so fast without this agitation.

Q. Before you go any further on that, I call your attention under the title "Conditions of Test under 41—The rate of flow through the pipe is to be 1 gallon per minute." That is the same rate you used in the other tests. A. We ran from the crock. Let me explain we ran from the crock to the steel tank and then we gave no six-hour agitation

but ran it immediately at 1 gallon per minute through the tubing in order that there would be no time to pick up the inhibiting metals in that tank, and we would have all the conditions of the Menaul process without any metallic inhibitors in there.

Q. That is your understanding?

Mr. Lightfoot: Yes.

(Witness continuing): But when we got through we found the iron picked up from the tank the acid got richer and richer in iron and lead, that the copper went along, and the acid was fairly well inhibited due to the metals by the time it got to the pipe. Therefore, we got a combination inhibition due to the metals picked up. It was sort of an odd test that we didn't include, therefore.

Q. Under Item 8, page 37, which bears the title "Condition of Equipment" is this entry—"To polarize the steel tank before the run it was filled with 200 gallons of 15% hydrochloric commercial grade and a lead electrode was placed in the acid and a storage battery fully charged was allowed to discharge through the solution. The battery was connected so that the lead plated out on the iron tank. The time of the discharge on the battery was 24 hours, i. e. the battery was allowed to remain connected for this period." A. That is about right. That is the polarization I described in the report.

Q. Then under page 40 is a diagram of the equipment and shows the same layout as was employed in the tests that you have reported here? A. That is correct.

Q. Under the title of "Conditions of Test" on page 41 the entry reads: "15% hydrochloric acid to be passed from the stoneware crock to the steel tank and directly through the piping system. The temperature of the acid to be 85° F., the hydrogen to be vented at the T, the rate of the flow through the pipe is to be one gallon per minute, the T in tank to be connected by electrical conductor copper wire. The tubing is not to touch the tank. Just before the run the steel tank was washed with 25 gallons of 15% hydrochloric. This was syphoned off and dis-

solved," does it not? A. That is correct. To make it more intelligible you want to put the emphasis on 15% hydrochloric acid to be passed from the stoneware crock to the steel tank and directly through the piping system. In other words, without the six-hour waiting period.

Q. Now, on the next page is a tabulation and the data of this run, and the run consumed from 1:52 P. M. to 5:06 P. M., as shown by the time-table in the first column. That is correct, is it not, Doctor? A. Yes, that is what it shows there.

Q. The data in this table shows much less corrosion than in the figures that you have presented in Exhibits 184 and 185, does it not? A. That is correct, and that is due to the picking up of the metals in going through the tank, which I explained to you—

Mr. Owen (interposing): What run does that data refer to that you have just mentioned? A. It is run B in that particular designation in the book. We have not reported that, because it was a combination of—well, we got partial inhibition, due to the metals in the solution.

Mr. Owen: That was one where you ran the acid direct from the steel tank, without letting it stand in there? A. Without letting it stand. Of course, the acid was in the steel tank for three hours, some of it. In other words, we put the acid in the tank and started to discharge it at the rate of a gallon a minute, but the test lasted for three hours, and, therefore, some of the acid was in there three hours, and the average was an hour and a half, I think, in there, and it is logical to think that that would—that you would get some inhibition there. We could not figure the iron because—and that is where we found out how we had to run these Menaul tests—the iron content in the Menaul tank would increase during a run, and we were innocent enough to believe that the tank would be inhibited by this lead sheet, and that the iron content would stay constant, and we took, as I recall, one sample—

Mr. Lightfoot: Two samples.

A. — two samples out of the tank, but in later work

we took a number of samples, every twenty minutes, so that we could have the iron concentration in the Menaul tank, and as it stood in the tank, the iron concentration went up, and we had to follow that curve, we had to follow the curve of the samples very closely, and so, taking only one or two samples, we could not make any calculations of that run of any accuracy at all, and I think that was the last Menaul run that we made in which we took only one or two samples for iron.

Mr. Wiles: Doctor, when you said you showed much less corrosion than shown in your report, you mean much less than the blanks? A. It shows somewhat less than the blanks. I don't know. You couldn't figure it accurately because we didn't follow the iron content in the sample. It is just an approximation. We made some blank runs later on these two sets of tubing, which we used in our report, and those runs dissolved 800 to 1000 grams of iron, somewhere in that order. This run, taking, even if you take those few determinations of iron in the tank and tube, which we found was not sufficient to show the content of iron in the tank, and figure it, it would be somewhat less than the amount of iron that went into solution in this particular run, and we explained it by means of metals that dissolved into the acid.

Mr. Lyon: Have you any figures in connection with this run B, how much lead or copper or iron was picked up by the acid in the tank?

Mr. Lightfoot: Maybe if we can look through the book.

Q. We will have to find that our later, because we can't stop to look through this book now. Now, the next entry in this DX-190 commences at page 46 and is entitled "Run No. C, December 21, 1939," that is correct, is it not? A. I don't recall the dates or anything else.

Q. And that entry, or the data on that run covers through page 53, and is signed by Mr. Lightfoot. Can you tell me—to shorten the matter, the data on that run, which is the first run used, first run in point of time? A. Yes.

Q. Which is used in either Exhibit 184 or 185, is reported run 1-M in Exhibit 185, is it not? A. This is the Menaul test. Yes, that is correct.

Q. This run at page 46, under the title of "Conditions of equipment, item 3," reads as follows: "Tubing" is grounded at the end to a water line and insulated at all other points of support." What was the purpose of grounding the tubing at the end to a water line, do you know? A. Yes, very definitely. In a well the tubing is grounded, and we wanted to ground that particular tubing to simulate as close as we could the electrical conditions in a well. The tubing is grounded and the truck tank is not grounded, because it is usually on a truck that has rubber tires to insulate it from the ground. We supported our steel tank on dry boards, several of them, to keep them off of any conducting material, to insulate the steel tank from the ground, but the tubing was grounded.

Q. And why did you insulate the tubing at all other points of support? A. That I can't tell you, but it is immaterial so far as any electrical action is concerned.

Q. Well, it is not because that is the condition in an oil well, is it? A. I don't know why they did that. I didn't give them instructions to do that. I had told them to insulate the tank and to ground the pipe, and they probably figured, well, if he wants the pipe grounded, we will ground it, and they wanted to know where they should connect the ground wire, and I think I told them the bottom end, but the rest of it, why—

Q. (interrupting): Had you given any thought to the possible effect of grounding that pipe at the bottom and insulating it at all points with respect to the matters we were taking about yesterday as to the potential at the bottom of the pipe? A. I don't think it would make any difference.

Q. Have you considered that? A. Oh, certainly, certainly.

Q. You don't think it would make any difference? A. That is right.

Q. What about stray currents? A. Stray currents, you mean from the ground? Well, if we had stray currents that would need any protecting, or anything like that, or the reverse, we would have found them in these runs.

Q. How do you mean, we would have found them? A. We would have found the inhibiting effect, if it was an inhibiting effect, or corrosive effect, we would have found them. We wouldn't have been able to have checked within about ten per cent as we have. There would have been tremendous effects, if there was any stray currents.

Q. Did you find any? Did you test for them? A. No.

The Court: What do you mean by stray currents? A. Stray currents, if there are differences in potential in various parts of the earth, and different structures in the earth, and due to these galvanic cells, or due to the loss from power lines, and so forth, leakage occurs and there are minute currents that migrate around, but if when you have a well grounded insulation, such as a water system that has about the same potential as the earth, and there is very little chance that you are going to get any particular current, or any current flow due to stray current action.

The Court: Just where is it grounded in an oil well? A. Well, the tubing goes down through a head, and the casing is in contact with the earth and is grounded all the way down, the earth or cement, which is grounded, and the tubing is connected to the casing up near the top of the tubing.

The Court: And then the grounding to the tubing is at the top? A. Well, it is, yes.

The Court: And from the tubing this would be—this would run back up to the top and over to the casing? A. That is correct.

The Court: And then from the casing out into the earth all the way around? A. Yes, that is correct, but what we were doing—I don't feel that it makes any difference—

The Court: Is this the theory, that the tubing hangs

down into either space or into water or into oil? A. Down in the well.

The Court: And that is not grounding? A. Well, sometimes it may rest on the ground, but usually it does not.

The Court: You don't call it grounding because it touches this fluid, whatever it is—that would not be grounding? A. Well, it would be grounded somewhat if there were acid around it in between the casing and the tubing, and there would be—if there would be under certain conditions you would have a grounding effect there; but the conductivity of the steel is so great—the electric conductivity, that if you ground a piece of steel, you do not have to ground a particular corner of it. If I have a plate, or a piece of steel, and I want to ground it, I can put a wire at the plate, at any point, and the whole plate will be grounded, because of the conductivity.

The Court: The entire casing being grounded, and the casing being metally connected to the tubing, the entire tubing is grounded? A. That is correct.

Mr. Lyon: The next test, or, the next run that was made is the one recorded commencing at page 54 of PX-190, and continuing through page 61, under the title of run D, dated January 5, 1940. This run is reported in Exhibit 185, under the designation 2-N, is it not? A. That is correct, yes, sir.

Q. The next run that is reported in PX-190, commences on page 62, and continues through page 69, and is signed by Mr. Lightfoot, and is entitled "2-B, dated January 13, 1940." Now, were the results of that run reported? A. They were not reported.

Q. Were they reported in either Exhibits 184 or 185? A. They were not reported.

Q. This was a run made with the Menaul tank, was it not? A. Yes, sir.

Q. And using the same type of apparatus that is diagrammed in Exhibits 184 and 185? A. That is correct.

Q. Under page 65, under the title "Conditions of

test," it reads, (reading): "15 per cent hydrochloric acid, to be passed from stoneware crock into the steel tank, and directly through the piping system; the temperature of the acid to be 85 degrees F.; the hydrogen is to be vented at the tee. The rate of flow of the acid through the tubing is to be one gallon per minute. The tank and the tee are connected by an electrical conductor copper wire. The tubing is not to touch the tank." Is that a description of the test? A. It is similar to test B, but it was run with different tubing, however.

Q. Pages 66 and 67 show a complete table of the results of those tests? The actual measurements made? A. It shows some of the measurements.

Q. And the first column is time, and the test started at 12:42 and continued through to 10 minutes after 4:00. A. That is probably correct, if it is down there, yes.

Q. And why did you discard the results of this run, 2-B? A. Because for the same reason we discarded B. We got the same results. We got a reduction in corrosiveness and we found that was due to metals that were picked up in that short time of contact in the tank. The acid was in the tank an average of an hour and a half, as I explained before, and our analyses of the acid leaving the tank showed it had more than two parts per million of copper towards the end of the run. And the loss of iron, even so, was—the actual amount of iron dissolved was 490 grams. It was right in between the blanks and the ones made with the Menaul process proper.

Q. Now, I will try to speed this up. The next run that appears in PX-190, in order, was dated February 5, 1940; and is run A and is reported between pages 70 and 77, and that is the run referred to in Exhibit PX-184 as Run 1-AA, is it not? A. That is correct.

Q. And the tubing used in that run was the tubing used in Run No. C? A. In Run C, that is correct.

The Court: Read to me what he says about the description of the test, like you did in the other.

Mr. Lyon: Conditions of Test, page 73: "Fifteen per

cent hydrochloric acid to be passed through the tubing system from the stone crock. Rate to be 1 gallon per minute. Temperature 85° F. The acid contains no added inhibitors." This was a test without the steel tank.

The Court: Will you read it back. I am sorry to bother here, but back in 2-N, what does it say back there about it?

Mr. Lyon: I think page 57 is what I should read in response to Your Honor's question, instead of page 65. This is 2-N. Conditions of Test: "Fifteen per cent hydrochloric acid to be passed into the steel tank and to remain in the tank for six hours with mild agitation."

The Court: I think I find the same thing on 1-M, probably; is that right?

Mr. Lyon: I think so. I will try to find it for you. Conditions in test of 1-M are reported on page 49 and read "15% hydrochloric to be passed into steel tank and to remain in tank for six hours with agitation."

The Court: That's all. You have answered my curiosity.

Mr. Lyon: Now, the next test in order is dated March 17, 1940, entitled "Run F" recorded in PX-190 commencing at page 78 and through page 95 and is referred to in exhibit PX-184 under the two designations of 1B, is it not? A. F is 1B in the report.

Q. The conditions in that test as stated on page 81 are as follows: "15% hydrochloric acid containing $PbCl_2$ $CuCl_2$ $FeCl_2$ so that concentration is similar to that obtained in run C after acid had stood in the tank for over six hours, to be passed directly from the stoneware crock to the tubing system. The tubing was that originally used in C. The temperature is to be 85° F and the rate 1 gallon per minute." A. That is correct. That was a synthetic mixture we ran directly from the stone crock.

The Court: That was run directly and was discarded? A. No, sir.

Q. We have two exhibits, PX-184 which I understand has no Menaul tank runs, all just runs from the stone

crock into the tubing, and PX-185, which reports the runs through the tank.

The Court: Is this right from the crock to the tubing? A. Yes, sir. The synthetic acid to which we had added the metals.

Q. Through each of these runs where there is a Menaul tank we found this same statement—that the tubing was grounded at the exit end, insulated at all other points. A. That is true in all the runs.

Q. The next run is dated April 6, 1940, and is entitled in Exhibit DX-190 Run G, pages 86 to 93, and that run is referred to as 1A in PX 184, is that correct? A. That is correct. That is another stoneware to tubing run.

The Court: Crock to the tubing?

Mr. Lyon: Yes, sir. The next run reported in DX 190, pages 94 to 101, as run H, dated April 13, 1940. The conditions of test of this run as reported on page 97 read as follows: "15% hydrochloric acid would be passed into the steel tank and to remain there for six hours with mild agitation. Then to be run through the tubing system at 1 gallon per minute at 95° F., the hydrogen to be vented at the tank and the T to be connected by an outside electrical connector. Tubing is not to touch the tank." There is a table and the results of that test on pages 98 to 99, and that test is referred to in Exhibit PX-185 under the designation 2M? A. That is correct.

Q. The next reported test in DX-190 commences at page 102 and continues through page 102 and continues through page 109, dated April 18, 1940, entitled "Run I." The conditions of that test as given on page 105 are as follows: "15% hydrochloric acid containing $PbCl_2$ $CuCl_2$ $FeCl_2$—so that the composition of the acid is similar to that in Run H—after the acid had remained in the tank for seven hours, the acid to be passed directly from the stoneware crock through the tubing system. * * *" A. This is the synthetic mixture with the acids introduced, run directly from the crock to the tubing.

The Court: They are doing in the crock what they contend has happened in the transportation tank?

Mr. Lyon: That is correct. "The acid to be passed directly from the stoneware crock through the tubing system. The tubing used was that previously used in D and H, the temperature to be 85° F., and the rate of the acid through the tubing 1 gallon per minute." There is a table of these results on pages 106, 107, signed by Mr. Lightfoot, and I will ask you whether these results were reported or given effect either in Exhibits PX-184 or 185? A. They were not.

Q. Why not? A. Well, the first thing when we completed the test and had our analytical work completed, which was some time after the test had been completed, we found that there was considerable discrepancy in the copper content of the inlet acid which was, as I recall, pretty close to 3 or 4 parts per million, but the exit acid analyzed (and we had a number of analyses on the exit acid) showed a figure of about 1½ or a figure of that order. Then we had run inhibition on the inlet acid and it ran very much lower. In the laboratory inhibition test no acid with that amount of copper was run. We didn't have enough sample left of this particular run to reanalyze and redetermine the inlet copper. The only thing that we could see was that something had happened in there that the weighing out of the copper salt or something that had produced some peculiar effect and we dropped that one out. We did not have enough.

The Court: It did show less copper than the other? A. Yes. The exit acid from the tubing was very low, but the inlet acid analysis that we ran, the first one showed it to be high, three or four parts per million, as I recall, and the inhibition that we ran on the inlet acid—we ran it in the laboratory test—was about half of what we got on other samples that had the three or four parts per million of copper and lead in it; and, therefore, we believed that for some unknown reason the copper content of the acid was not correct, and not having enough samples to go back and run the inlet acid over again, we decided that we would not report that result.

Mr. Lyon: How about the actual amounts of corrosion, the dissolved metals, as reported in the different measurements in this test, compared with other tests? A. I believe the corrosiveness was fairly high. It was about—

Q. Will you examine this and see (indicating)? A. I cannot tell from the figures. You have got to calculate it. You have got to take all these figures and make your calculation. You remember about what it was, Bill? Was it 500 grams, or something like that?

Mr. Lightfoot: I don't know, but I can calculate it.

Mr. Lyon: Was it lower or higher than other tests? A. I don't know. I don't remember.

The Court: Let me ask you this question, if all your tests had been comparable to this, and had run like this, would the results have been more favorable to Halliburton and less favorable to Dow? A. It would be more favorable, definitely to Halliburton, but still that wouldn't change the degree, it wouldn't change the picture, but—

The Court: I just want to get it squarely on the record, and in my head, that these were some results that would have been more favorable to the other side, if correct? A. If correct, yes, and we have all the figures there that they can see.

The Court: How much more so, speaking generally? A. Well, that I cannot tell unless we have got all of the figures.

Mr. Lightfoot: The iron was in the 400's.

Mr. Lyon: As compared with 1000 for the other tests you reported? A. The blank was 1000, the uninhibited acid, and this acid which was made up to duplicate some of these tank truck acids with lead and copper ran about 400, or maybe between 400 and 500, according to Mr. Lightfoot, instead of two to three hundred that we reported on the other figures. In other words, instead of an inhibition of 70 to 80 per cent, it would have been 60 per cent, and we had an explanation for that drop.

The Court: Now, let me ask you this question: What do you think if this had been, this one, had been as much

more favorable to Dow and unfavorable to Halliburton as it was favorable, do you think you would have discarded it entirely under all of the circumstances, or do you think you would have reported it for whatever it was worth, what do you think about that?

Mr. Lyon: I would ask him to remember run 2-A which said report shows about the same amount out of line in favor of Dow, when he answers that question. A. Well, I think that this is further out of line than any of the things reported, and some of the others are out of line, I will grant you that, and regardless of the—when you look over a series of data, if you see one of them more out of line than others, I think you are permitted to drop that, particularly if it doesn't change the over-all picture.

The Court: Is this more out of line in favor of Halliburton than some of those recorded, I mean the others recorded are out of line the other way? A. Well, as I recall this is more out of line. And you can't—you have to look at a whole series of numbers to figure out whether it is out of line or not, and it is difficult to put your finger over one definite thing and say that that is the thing that determines whether it is out of line.

The Court: The question I have just asked is largely the substance or purpose of going into all that? A. Yes.

The Court: I thought I would go directly about it and not beat around the bush at all.

Mr. Lyon: All right. Now, as a matter of fact, compare the amount that run 2-E, which you reported in Exhibit PX-184, with this particular run that you have just been asked about, and tell me how much more this run is out of line than run 2-E is out of line? A. What is 2-E? Let us get the book.

Q. 2-E is out of line in Dow's favor, and I think you mentioned it yesterday as out of line. A. I think in my testimony I have indicated that in running a large scale set-up like this that there is certain leeway, and I have indicated this 10 per cent and so variation. I don't believe that you can run a large scale practical test, or make it prac-

tical and get the fine exactness that you can get in a scientific laboratory with a gram of material, and I have indicated that, and if this would have changed completely the picture I would have studied that to the nth degree. The picture we have presented, this does not change the picture one particle.

Q. I am not asking you that, and I object to the witness arguing on cross examination, Your Honor. I have asked him to compare run 2-E which he did report in PX-184 in which he has admitted already out of line in Dow's favor, the amount that that is out of line with the amount he says his tests we have just been inquiring about was out of line in Halliburton's favor. A. 2-E. It is out of line in the fact that it showed a lower amount of corrosion. But I don't recall any of the things that you determine in throwing the test out. Those are the things, when you collect a whole bunch of data and figures and you pick one and use it, you find some holes in that data, and then you find the differences and discrepancies in these, sometimes you throw out the final answer and the whole thing.

Q. I am not asking you that. I am asking you to point out, the point of my question, is Exhibit 2-E any more or any less out of line in this report than this test we have referred to in Exhibit 190 which you threw out? A. All of the work, as I recall the data that we took, the evidence indicated that 2-E was a valid run and I reported it in No. 1.

Q. I am not asking you that. Is it out of line compared with the other? A. Out of line in what way?

Q. With the results of other tests you included with it, by as big a margin as the figures of this discarded test? A. If you take that view of it, no.

Q. How near is it? A. I would say that the Menaul tests in these synthetic acids—

Q. (Interposing): I am talking about 2-E. 2-E. A. That is right. If I am saying something is out of line I have got to compare it with something it is out of line with. About the average of synthetic acids in the Menaul tests

might be 250 grams of iron dissolved, somewhere in that range. Very close to it. The synthetic acids in the Menaul tests all showed about 250, and the blanks 1,000. This was 101.4 grams from our analyses. That is a difference of 150 grams, from 250.

Q. How much per cent is that out of line from 250? A. Well, now, I say it is 150 grams of iron different.

Q. Then out of 250 it is 150 off, is that correct? A. It is off, if you take the averages of different kinds of tubing and the tests made, the average of averages.

Q. You have given the figure 250 as the proper starting point now, and this result which you reported in 2-E in Exhibit 184 is 101. A. Yes.

Q. Therefore, it is about 150 out of line from 250? A. That is correct.

Q. And you reported it? A. I reported it.

Q. All right. Now, how much in figures was the Test I in Exhibit 190, which you have referred to and which you threw out, out of line? Give us the figures? A. If it was 400 to 500, why it probably was—

Q. (Interposing): I didn't say "if." What are the figures? A. I don't have them.

Q. You gave the judge a direct answer a few minutes ago. A. I did not.

Q. To his question? A. I gave him 400 to 500.

Q. It was an important question, I thought. Now, what are the figures? Let's see if you are justified in your answer as to why I, being more out of line than Exhibit E-2 which you included. I want to know what the figures are. A. The answer that I gave the judge was based and the discussion that I had with the judge was based upon the numbers that we accumulated in getting this final calculated result. That question was whether the conditions were more out of line and the test was more out of line than the one which we incorporated, any one we incorporated in favor of Dow, and I say that the analytical figures as we went along indicated that there was something wrong with this work.

Q. You refuse to answer my question? A. No, no; I have answered your question.

Q. Answer it. A. But I refuse to answer the question to imply that I answer wrong to the judge.

Q. Just answer my question, if you will. A. I did not give the judge and I did not give anyone a definite figure for the amount of iron dissolved in this particular run. I said that according to Mr. Lightfoot it was 400 to 500 grams of iron dissolved, and if you take this figure of 250, the difference would be from 150 to 250 grams.

Q. I am not asking you that. If you will answer my question and stop arguing, why, we will get—avoid any misunderstanding. I asked you to give me the figures for the Run I which was discarded, what the starting figure is for comparison that you think is in line with the actual figure that you got in Exhibit I. I want to know how much it is different. A. I do not have the figure.

The Court: Where are they? Aren't the figures here? A. I don't think that we have them calculated. When we found that these analyses were off, I don't think we went through, and we kept that—

Q. (interposing): Doesn't Exhibit I—doesn't the data in DX-190 on Exhibit I show that 670 grams of iron were dissolved? A. I don't recall that it does.

Q. Will you look at it? It is right there. A. Will you look at it? (to Mr. Lightfoot).

Mr. Lightfoot: You mean this?

A. (After conferring with Mr. Lightfoot): The figures that are given in the book there on the iron content of the solution were run by an analytical procedure that is known as the gravimetric method for iron; and we found out after we had run a number of tests, that that method could not be used in the presence of lead, and this run had lead in it. The samples were taken and run for iron by a method which we verified in the presence of lead, a volumetric method, the dichromate method, and the analytical figures—I am not sure that we have them on this particular run, we had thrown them out on the basis of the figures or

analysis during the run, and I don't know whether we have the figures on this new method of iron analysis, but if we do, we can make the calculations.

The Court: When you started to make that run, you knew that there was lead in it, did you not? A. We knew that there was lead in it.

The Court: Didn't you know that you had a method that you could choose where you had lead in it? A. The method—we had samples that contained different amounts of lead. We had raw acid that had very little lead in it, and the gravimetric method there worked very well with the small amount of lead, but in some of these samples where the lead went up high, the gravimetric method would not work.

The Court: Is that something that was learned in this very experiment, do I understand? A. No, not in that very experiment. I don't recall exactly when it was learned.

The Court: I don't get the point. A. Well, the point is—

The Court: That you started this because you had used a method that was not applicable? A. No, no. We had analyzed for copper in the samples of acid, and we had analyzed the original acid for inhibition in the laboratory tests and we found that gave a very low inhibition and the analysis of the effluent acids, which was very low in comparison, which was not found in the other runs, and we decided that there was something wrong with that test, so we discarded it. Now, we subsequently learned that the method that we had used for determining iron was not only taking down the iron, but taking down some of this lead, and we ran all the samples that we could get to determine the iron by this new method, and this run which we had discarded, I am not sure we ran over again for iron. Do we have those figures?

Mr. Lightfoot: Yes.

A. He said we have them, so we can calculate this exactly, and we will do that, if you want it.

Mr. Lyon: I certainly do. A. Will you make a note to that effect?

Mr. Lightfoot: Yes.

Mr. Lyon: The next run in this book is run J, dated April 26, 1940, reported in PX-190, commencing at page 110 through page 117. A. That is 2-B, run 2-B in the report.

Q. And the next run reported in PX-190 commences at page 118 and runs through page 125 and it is dated April 30, 1940, and is entitled "Run K," and that is referred to in Exhibit PX-184 as run 2-A? A. That is correct.

Q. Then the next entry in PX-190 is directed not to further runs, but to what are entitled "Changes in procedure for chemical analysis"? A. That is correct.

Q. And they cover from page 126 to page 130 and are then followed by the entries of various actual chemical analyses determinations up to page 157? A. That is correct.

Q. Now, various of these chemical analyses which you reported at this point in PX-190 bear notations such as the one on page 131, which is entitled "Iron analysis," and you have written there "Not used in report." Did you make the decision not to use these various results as indicated in Exhibit 190 in the report? A. I think that is my handwriting. I am quite sure it is.

Q. Then we have another one on page 133 entitled "Chemical analysis, run 2-B, methods and results discarded," that is correct, is it not? A. Yes. Run 2-B is the one that we ran the acid through the crock or tank and then out.

The Court: Now, this is showing that—have you referred to another one there too?

Mr. Lyon: There was run A, it says "Not used in report," page 131. The item on page 131 there refers to run A. The item on page 133 refers to run 2-B.

The Court: What is the date of the one you called A?

Mr. Lyon: Run A—the first run in the book, November 24, 1939. That was not used.

The Court: Now I have got just three that were not used.

Mr. Lyon: You have got A, B, 2-B, and I were not used. A. Four runs.

Mr. Lyon: A, B, 2-B, and I. If you want the dates of those, run A was November 24, 1939, run B was December 16, 1939, run 2-B was January 13, 1940, and run I, April 18, 1940.

The Court: I have got it right now.

Q. Now, then, the next we have, commencing at page 135 of PX-190, the chemical analyses for run C, which run was dated December 9, 1938, and is run 1M in Exhibit 185. We stop making runs in this book and make chemical analysis.

The Court: Let me call attention to the fact B is the one I have used more than once. I have 2B not reported. That is the only time I have used one letter more than once. And neither B was reported. B wasn't reported and 2B wasn't reported.

Mr. Lyon: That is correct.

The Court: Now, I haven't in my mind the relation. We start a series of letters—A, B, C, and D. They bear some relation to each other. I haven't in mind the relation between B and 2B.

Witness: B was run with acid going into the steel tank, immediately out. 2B was run in exactly the same way. The same letter was used to designate the same type of run.

The Court: The same in every way? A. Excepting the tubing was different. Isn't that right?

Mr. Lightfoot: Yes.

The Court: You not only ran them in the same way but got—

Witness (interposing): —the same general results.

Mr. Lyon: Now, Your Honor, at that point in Exhibit PX-190 the entries take up the change in analytical methods and record chemical analyses, the results, and later as we will see, they take up additional subsequent runs. Beginning at page 135 under the title "Chemical Analysis Run C" are the results of chemical analysis on run C; and the

first values are given as item No. 1, entitled "Iron analyses," run 12-28-39; and there is a notation here in pencil. Your Honor, all of these entries are all in ink—I haven't stated to Your Honor that all of the regular entries in PX-190 are in ink, but some of these notes are in pencil. In the margin is written, "Results not used in report." Is that because you had to recalculate these results by some other method? This is entitled "Iron analyses gravimetric method." A. We did not use the gravimetric method in the report. I told you that the gravimetric method was used on some samples, and then we repeated and re-ran those samples with the volumetric method, which is the accurate method, and so we did not use those, and, as I recall, I went through, and where we had used the gravimetric method—

The Court (interposing): Did you know before you ran them that one was an accurate method, and the other not? A. No, because iron and lead is a rare combination to get together in a solution, and the methods that I have described in the determination of iron—in most of the text-books, they do not mention that lead is an interfering element, and it did interfere to some extent.

The Court: But did I understand you found out as a result of these runs and the experiments and analyses that it was inaccurate, in the reports? A. Exactly. The reason it was found out was this: These men that were running the analyses, the final determination is that you weigh up iron oxide after precipitating it out of solution, and iron oxide is red like iron ore and should be fluffy and hard, and I noticed on some of these samples, I just happened to pick up the crucible and inspected it and noticed that the iron oxide had become fused into the porcelain of the crucible, and iron oxide will not do that at the ordinary temperature of ignition, but lead oxide will do it, and, therefore, I suspected that some of the lead was coming down with the iron and gave us a high result on the iron, so we took the volumetric method and made up standard solutions of iron and iron containing lead and determined that

we could accurately find out the content of iron in the solution by that volumetric method, and we repeated all the analyses.

The Court: What I wondered, is that some information now that you can apply to all other tests all the rest of your life, that the one is accurate and the other not accurate, or does it simply mean that for this particular test it is. A. (interposing): Oh, no.

The Court (continuing): — it is not accurate. A. We used this volumetric method for every iron figure that is reported with the exception of one or two figures that are run by the gravimetric method for the raw acid or acid that did not contain lead. There are a few of those gravimetric figures that we did not re-check because there was no lead in the solution, and we know that that is an accurate method when there is no lead in the solution.

The Court: Why use the gravimetric method at all, ever again, then? A. Why, we had started out with the gravimetric method, and we are not going to use the gravimetric method in this book from then on.

The Court: I know. But are you ever, as long as you live? A. Oh, yes.

The Court: I am wondering whether it is something that is not an accurate method or— A. (interposing): No.

The Court (continuing): — whether it is simply something in connection with this. A. In connection with this case, the fact that lead and iron were both present in solutions, and there was an appreciable amount of lead in solution was the thing that made that method inaccurate for the determinations. If lead had not been present, if it was just iron and copper—

The Court (interposing): But you knew lead was present. A. We knew lead was present.

The Court: Well, did you know that when lead was present that the gravimetric method was not accurate or did you first learn that in your lifetime there? A. I am just trying to figure out how the method of analysis was started in. You see, I had two men that did my chemical

analyses, Reihl and Halverson, and as I recall it we had samples of the raw acid that had practically no lead in, and I told them in a brief discussion to use the gravimetric method, without any great amount of thought about the lead, and I think that if I would have given it any serious consideration, looked it up thoroughly in the literature, I would not have told them to use that method, and when I saw these fused precipitates I knew that they did not have pure iron oxide, and the method was not working, and then we went back and I personally ran about 90 per cent of all those iron determinations by the volumetric method, and the others reported are by the volumetric method, which we have proven to be accurate.

Mr. Lyon: The next item I call your attention to is No. 3 at the top of page 136, entitled "Chemical analyses, Run C, continued, lead analysis," which was run on 1-10-40, and a legend reads, "Crock comp." What does that refer to? A. I would think that would mean composite, is that correct?

Q. That means this synthetic composite of the crock? A. Yes.

Q. And the value of that in milligrams of lead per c.c. is .0059. Then the next item is composition of tank and the value is .39, and then the composition of the end is .49. What do those values indicate? A. They indicate that in this—that was run C, wasn't it? The crock acid was commercial acid diluted to 15 per cent with tap water, and that very low figure for lead is the lead content of that acid, practically no lead in it. Then the composite of the tank samples are the samples that were taken from this Menaul tank during a run and were analyzed and showed .39 milligrams per c.c., as you read it there. The acid leaving the end of the pipe was analyzed and showed .49 milligrams per c.c.

Q. That is correct. Now, does that indicate that the acid in its progress down the pipe picked up some more lead? A. No, it doesn't indicate that at all. It indicates what I have explained to you before, that in this Menaul

tank that lead chloride, when this sheet corrodes in the acid the lead forms lead chloride, and that lead chloride becomes some dispersed in the acid at the bottom, the acid in that tank during a run, which is not stirred, during a run was just drained down, when you dip the bottle into that tank the most concentrated acid is down near the bottom and it is from the bottom that the end of that tube, the tubing system is sucking the acid from the top of this lead plate where the concentration is greatest, and therefore it is logical to expect that the effluent acid which is being taken always from on top of that lead sheet, being sucked very close to the lead sheet, would be greater than samples you would obtain by dipping into the tank. And the other thing is if we had felt that was of any major importance, we would have made much greater investigation than we have of that.

Q. Isn't your statement a mistake there was no agitation in this run C because if you refer back to page 49 under the conditions of test run C don't we see that "15% hydrochloric acid to be passed into the steel tank to remain in the tank for six hours with mild agitation"? A. There are two steps there—three. You take acid from a stoneware crock, run it into a Menaul tank, then you spend six hours and occasionally stir the acid. You get agitation then. When the run starts, you don't stir it. The only agitation you get is by the 1 gallon per minute of the acid being sucked into the tube; so during the test there is no agitation.

Q. But during the six hours there is. A. Yes, but the samples of the inlet and outlet are taken during the test.

Q. In stating the composite of the tank was .39 and the composite of the outlet was .49, does the latter refer to the analysis of the material as it comes out of the bottom of the tank? A. The .49.

Q. Now, then, the lead content of the acid as it went into the pipe at the top was .39 and as it came out it was .49, wasn't it? A. I explained to you that that wasn't the case.

Q. I don't understand the explanation. A. Here you have a steel tank with some hydrochloric acid in that has been agitated for this six hours occasionally. During that time the lead sheet has corroded and formed lead chloride and some copper chloride. The lead chloride doesn't all go into solution and be evenly dispersed in this acid. There is some lead chloride of a thin whitish film on the lead plate. The lead chloride on the lead sheet which, of course, is being continually formed, and the loose particles which is dispersed not dissolved then tend to accumulate in the bottom of the tank; the concentration at the bottom when you let it set is greater than at the top. When we took samples of the composite of the tank we dipped into the tank and took the sample. The tube which is delivering the acid out of that tank was just an inch or two above that lead plate, so it was sucking acid by that lead plate, and naturally would have a higher lead content than samples we dipped out of the top or dipped out of the middle of the acid. That is why the exit acid in this run is higher than the inlet. As I said before, the reason it didn't disturb us much was it was very easy to see this lead chloride that we have shown and other people have shown, that the amount of lead in the range of .39 or .49 is substantially the same as an inhibitor.

Q. Well, then, you don't have an actual figure here for the lead content of the acid as you put it into the top of the pipe? A. I didn't say that. I believe the stuff coming out the bottom is substantially the way it went in.

Q. I am not asking you that. You don't have an actual figure— A. (Witness interposing): Of the analysis of the lead content going in. We do not.

Q. Do you have a figure for the actual lead content of the acid introduced into the top of the pipe? A. For all practical purposes the .39 is a good figure and .49, or an average, any way you want to take it.

The Court: What I understand you to say is you think it is higher in lead. I don't think it makes any difference but you think it actually is higher in lead content

than the average of the whole thing. A. At the bottom, right at the lead plate.

The Court: I say that you put in— A. (Witness interposing): Yes, that is correct.

Q. (By Mr. Lyon): Is that true of the figures you have reported PX-184 and 185 as to the lead content of the acids introduced into the top of the pipe? Are they subject to that same correction? A. I don't know what the figures are. I would have to see them.

Q. You know the figures, don't you, in Exhibits 184 and 185? Maybe you better take a look at them. Figures for the synthetic acids and the figures for the tank acids where you have given the lead contents, and tell me whether they are subject to this same explanation that you have given here? A. (After examining documents and books): We will have to get it out of the book. It is not in the report. Do you want us to go through the book and get the figure?

Q. Don't you report in Exhibits 184 and 185 that these were the amounts of lead that you found in the tank acids or the composite acids? I am talking about the inlet? A. Oh, the inlet?

Q. Yes. A. The figures are given in the report.

Q. Well, now, are they subject to the same explanation and correction that you have referred to in connection with this figure of .39, or did you use these figures— A. (Interrupting): I don't think you would get the same difference in runs—you might—if this pipe were right down on the lead sheet, you would get quite a bit of iron in the effluent acid. If the pipe were to—

Q. You must have misunderstood my question, because you are not answering it at all? A. I did not understand it then.

Q. You reported in Exhibits 184 and 185 figures of the lead content of the acid that was introduced into the top of the pipe? A. That is correct.

Q. Did you use these figures that I have been referring to in Exhibit 190 without correction, or did you correct

them in any way to take care of the feature that you have been referring to?

Mr. Wiles: You did not mean to include the exhibit that had the synthetic acids in it, because this factor does not exist there at all. There is nothing about synthetics.

Q. Well, I don't know about that. Well, all right, let us limit it to the Menaul acids. A. The figures that we reported in the report are the analyses of the samples that we dipped out of the tank.

Q. You did not make any correction? A. We did not make any correction for the effluent concentration.

Q. Let us refer to the next item No. 4 on page 136 of this chemical analysis for run C. This is entitled "Inhibitions, small metal samples, sample, weight, loss, inhibition," and there is the series from C-1 to C-8, and the weight losses are given. The inhibition is expressed in grams, meters per hour—I think that is meters, "Grams m. per hour"? A. I think it is meters.

Q. And the per cent is given, and for C-1, there is no per cent. For C-2, it is given as 28.5; for C-3, it is 32.0; for run C-4, it is 33.6; for C-5, it is 33.3; for C-6, it is 29.3; for run C-7, it is 28.6, and for C-8, it is 34.2. Then there is a marginal note in pencil, "Not used in report." Now, will you explain that table, and explain what the tests were, what these percentages are, and why you did not use them in the report? A. When we started in with this work we knew that Dr. Bartell was employing a small specimen in an inhibition test and a small volume of acid, and we used that in measuring the inhibition of acids in some of these tests as reported here. And the inhibition of our commercial acids all ran about zero or very close to it, within a few per cent of zero, on the same small test. And the inhibition of these synthetic acids or Menaul acids that we ran all ran around 30, between 30 and 40, which is very similar to the results Dr. Bartell got on the field samples that they had obtained.

But when we ran it through the big tubing here we got 70 per cent inhibition. And the thing that we couldn't ex-

plain was the difference between the inhibition obtained in those small scale tests and in the large scale test. We then thought that the results were probably due because the cutting of the little piece of metal used to work it and deform it a great deal, and therefore you have got a peculiar surface, the volume and the time in contact, and so we went to the method that we used in our subsequent inhibition tests for laboratory purposes.

We simply took a piece of actual tubing and we gave it the same type of cleaning as the tubing got in the large scale tests, and we used the same mass or volume of acid and area in contact with the acid that we used in the large scale tests and used the same time of contact that we did in the large scale tests. The only thing we couldn't duplicate was the agitation. And then we got very similar results in the laboratory and in the large scale tests.

And so in the small scale tests the inhibition there says "Do not use" simply because I don't recall that we reported any inhibitions in the report except this large scale, the one with the one inch collar of iron, of oil well tubing, the second laboratory test which we developed which gave us correlation with our large scale tests.

Q. Are these small scale tests that you refer to all these tests made with these samples? A. Made with the small specimens.

Q. They were made under laboratory control conditions, were they not? A. Yes, they were controlled.

Q. Carefully made? A. Well, I would say they are fairly carefully made, yes.

Q. Well, now, they all showed very much lower percentages of inhibition than the tests that you reported in Exhibits 184 and 185? A. That is correct.

Q. And you continued to make those tests of that kind and obtained those kind of results throughout all your work, did you not? A. No, sir.

Q. When did you abandon them? A. I don't recall when. Can you tell, Bill?

Mr. Lightfoot: I think starting with run 1-N, as listed in that book.

A. Run N in the book.

Mr. Lyon: When was run M made, can you tell us? A. Yes, I can give you the date. M, 12-23-40, December 23, 1940.

Q. That was made a year after your run A? A. Yes.

Q. And you continued to make these laboratory tests for the per cent of inhibition of reduction of corrosion and obtained uniformly all these results down around 30 per cent? A. 30 to 40 per cent.

Q. And you excluded them all from your reports, reports to the court here, that is correct, isn't it? A. We excluded them all?

Q. Yes. A. Yes, because we had this correlation between the laboratory and large scale tests and we felt this large scale test was a very valid test, and therefore to get a test that would correlate in the laboratory we could study acids before we ran them in this large scale test, if we wanted to, and therefore we wanted a laboratory test that would give us a practical result that would resemble in some way what we got in the oil well tubing.

Q. I notice on page 145, PX-190, a table entitled "Inhibitors, inhibitions, runs A through G. These inhibitions were run on the samples on the modified method, using 50 c.c.'s of acid, suspending the sample by glass hook from the specially prepared cap." I don't know what that is. A. Cap, I guess.

Q. Cap time 16 hours, sample and location is the first legend, losses is the legend for the next column, area is the legend for the next column, inhibition is the legend for the next column, and per cent the last. I suppose that refers to the per cent reduction in corrosion? A. Well, I would think so. Let me see.

Q. The date says run 5-7-40. I am going to read you parts, giving just the identification of the samples, and their location and the percentage of reduction of corrosion. A. All right.

Q. Sample A, location Crock, per cent—(reading from table): A End Composite 6%; 2B Crock 0%; 2B Tank

Composite 9.6%; 2B End Composite 16.5%; C Crock 0%; C Tank Composite 28%; C End Composite 26.6%; D Crock 0%; D Tank Composite 34.2%; D End Composite 34.3%; E Crock 0%; E End Composite 13.8%; F Crock original—and there is a star here in the footnote saying "Not Run" "Use D as 42.0 the average of the crock original for runs A, 2B, C, D, E and G; sample of crock and metal percentage 21.9%. Then Sample 1 End Composite 26.0, Sample G crock percentage zero, sample G End composite 5.8," and that is the rest of the percentages. Now, these samples designated, do they refer to the letters of the original runs as they were originally lettered? A. In the book.

Mr. Lightfoot: That is right.

Q. And the sample by crock means the sample was taken out of the crock? Mr. Lightfoot: Yes.

Q. And the end product means it came out of the tube at the bottom? Mr. Lightfoot: Yes, sir.

Q. The tank compound means the sample was taken out of the Menaul tank? Mr. Lightfoot: That is right.

Q. None of those results were reported in Exhibits 184, 185? A. No, because we felt those small tests did not represent what happened in an oil well tube.

Q. I am not going to take the time to point out the corresponding determinations and the results that were made with each one of these different runs. They are all here in the book, aren't they? Because your explanation covers them all. A. You mean the explanation of the small scale test?

Q. Yes, sir, as to why they were left out and they were left out. A. They were left out because we didn't feel that small scale test gave us a practical measure of inhibition. We ran the large test which we felt was much more comparable to certain figures, and we got the figure repeatedly in a total of eight runs. The second method of running the test in the laboratory we used the 1" pipe and gave results that compared close to the large scale flow tests.

Q. All right. That brings us up to page 156, because

I won't stop with the other analyses on the runs that have been performed up to that date. That brings us to a matter of copper analysis for runs K and L. You had to make a change in your method for analyzing for copper, didn't you, in the progress of this work? A. Yes, the method that was originally used for some of the earlier work was the method that we discussed this morning, earlier today, in the front of the book there. It was the first method received from Dr. Bartell and we learned that very shortly after he had sent us that method that he changed over to that other method he obtained from Dr. Willard. When we were apprized of that, we changed over and the figures reported in the report are all based upon this second method for copper.

Q. What did you do? Go back and re-analyze? A. Analyze all the samples we had to determine the content of copper.

Q. (By Mr. Lyon, continuing): Then, as a matter of fact, you originally analyzed these various samples from these various runs for both iron and copper by methods that you afterwards discarded, and you had to re-analyze all those samples by new methods, for their iron content and their copper content, is that correct? A. Not all of them; some of them.

Q. And that work of re-analyzing was done about a year after the runs were made, and after the original analyses were made, isn't that correct? A. That is correct. The results that were obtained, however, did not change the picture or the conclusions one particle. The analyses were—it was an academic study more than anything else. The loss in weight of the tubing that we calculated, and the per cent in difference that we found in the last were just within a per cent or two.

Q. When you say the results did not change, or that these differences in figures did not change the results, you mean within your interpretation of what the important result is; you don't mean that they did not actually change the figures supporting them? A. Oh, yes, they changed the figures. For example, when we ran a sample of acid

from the Menaul tank, it may have had one and a half milligrams of iron in it, and a half a milligram of lead in it; and we ran that by the old iron method, and we probably found 1.6 or 1.7 milligrams of iron there, a high result. That is in the Menaul tank. Now, in the effluent acid, we used the same method, and the effluent acid probably was 2½—let us say—or, two of the true value, and it had lead in it, and we probably found 2.1; in other words, both figures were up by the same amount, and although there was an error in the method, we got 1.6 milligrams in the Menaul tank, and 2.6 in the effluent. That is the difference which we used to calculate. The iron remained the same. And, therefore, after the iron had been repeated, the same conclusions were obtained, that there was 60 to 80 per cent inhibition in running the Menaul tank, the Menaul tank without wire, and the synthetic acids—the picture was exactly the same.

Q. Well, now, wait a minute. You say that the difference would remain the same, but the values were changed, raised or lowered as the case may be. A. Yes.

Q. Well, then, as you were reporting the results as a percentage, the change being a percentage of the whole, that would change that per cent. A. We don't do that.

Q. What do you do? A. We use the figure for iron in the inlet acid and the figure for iron in the effluent acid and take the difference to figure out how much iron has been picked up.

Q. But you report per cent of reduction in corrosiveness here based on those differences? A. No, sir; absolutely not. Those figures are not used for that purpose.

Q. Now, tell us about the copper. What actual difference in values did it make in these differences in the measurement of copper? A. As I recall the copper, the first method was the colorimetric method as well as the second, and the only recollection I have that was wrong with it was that it produced a color and that that color was fugitive. In other words, it would go away in time, and they had to adopt a standard procedure of just measuring

the color at the end of a certain time and that was not very convenient, and, therefore, there was a chance to make some little error there by the observer. And in the second method that color stayed and was quite permanent. Isn't that the main difference?

Mr. Lightfoot: Yes. A. That is my recollection of the two methods.

Q. Well, was there more than two methods? A. No.

Q. That you employed for copper? A. No, there was just two methods.

Q. You haven't tried any other method since? A. No other method for copper.

Q. I notice on page 156 a table entitled "Copper Analysis, Runs K and L, Carbamate Method." A. That was the second method.

Mr. Lightfoot: Yes.

Q. That was the method you actually reported? A. That is the good method, better method, of the two.

Q. That is the one you used? A. That is the one on which the figures are based, on the carbamate method. All the figures in the report are based on the carbamate method, as well as Dr. Bartell used that method.

Q. I notice on the left hand side of this page a note, "Results Discarded." But on the bottom of the column it says "Above samples analyses enclosed with report but questionable due to color interference." Will you explain that in the light of your testimony? A. The analyst that ran these samples wrote along the side of them "Results Discarded. See page 154 for re-run." In other words he must have noticed something was wrong or he did something wrong. "Above samples analyses enclosed with report but questionable due to color interference." "Above samples," that must mean these top ones. I can't interpret that last sentence there. Were these figures used?

Mr. Lightfoot: I don't know. A. I would like to have the book and take time to check it and find just exactly—

Q. (Interposing): You do that. We are going to

have two hours at noon, and I hope you can do it in that time. A. All right.

Q. It takes a long time to check some of these things. Now, the next entry in this book commences on page 158 and is entitled "Run L," dated May 11, 1940. And the write-up for that run goes through with the entry of results through page 165. And the Conditions of Test on page 161 are stated as follows:

"Fifteen per cent HCl to be passed into the steel tank and to remain there for approximately six hours with mild agitation. Then to be run through piping system at approximately one gallon per minute. The temperature of acid to be 85° F. Tank and T are not to be connected by any outside connection." And that run L is referred to in Exhibit PX-185 as run 1-N, is it not? A. That is correct.

Q. The next entry in the book begins on page 168, entitled "Run M" made December 23, 1940. The write up for that run continues through page 175 and the conditions of the test are stated at page 171 as follows:

"413 N HCl acid treated with $FeCl_2$. 4 H_2O $PbCl_2$ and $CuCl_2$ to be passed from the stoneware crock at 1 gallon per minute at 85° F. through the tubing system." That run is referred to in PX-184 as run 2-D, is it not? A. That is correct.

Q. The next entry in the book commences at page 176 and is entitled run N, dated January 7, 1941, and the write up for this continues through page 183. The conditions of run N are stated on page 179 as follows:

"413 N HCl acid was passed directly from the stoneware crock at 1 gallon per minute at 85° F. through the tubing system."

This run is referred to in PX-184 as run 2-C, is it not? A. 2-C is correct. That was reported as 2-C.

The Court: That goes direct, is what I was getting at. A. It goes directly into the tubing.

The Court: It didn't go in the tank at all? A. That is right.

Mr. Owen: It ran from the crock and went directly from the crock.

The Court: That doesn't apply to the reason why some earlier ones were discarded, because they didn't stay in the tank? A. No, it wasn't in the tank at all.

Mr. Lyon: The next is a write up commencing on page 184 entitled "Determination of Iron," and this continues through page 188, and I am going to pass it for the time being, but it has to do with the new method for analyzing iron. A. That is right.

The Court: That one of May 11, 1940, L, I should mark it reported; is that right?

Mr. Lyon: Yes. May 11, 1940, Run L, is Run 1-N in Exhibit 185.

Q. Now then we come to page 189, to what is entitled "Chemical Analysis of Run M" and No. 3, Item 3 is entitled "Copper Analyses, Carbamate method." A. That is right.

Q. That is the method that you say you adopted and actually used in your report? A. That is right.

Q. Now, there is quite a table of these copper analyses, and I notice a note on the side, "Discarded See page 256." Have you any knowledge of that? A. I will have to look at it.

Q. You have turned over to page 256. That has a table entitled "Re-Check of copper analysis, Runs D, J and M."

The Court: Can you tell us the occasion of making those and discarding the earlier figures? A. There is no date down here, so you couldn't tell just when they were run. We would like to check these figures.

Mr. Lyon: We were just calling attention to the fact that they had discarded certain copper determinations, and then it referred to a later page in the book, and there was a re-run of them, and the witness is going to make a statement. A. I would like to check the figures in the first table and in the second table with the figures used in the report. I just don't know what happened. (Checks figures.) The re-check, apparently, is just the same as the original determinations.

Q. Let me have the chemical analysis in run N on

page 190, and then on page 191 we have a table, "Chemical Analysis of acids from tanks," on page 192 we have a title "Study of facts involved in determining the rate of attack of acid on oil well tubing," and at page 193 we have a title "Time of contact versus rate of attack," page 194, "Time of contact versus rate of attack," on page 195 "Effect of ratio of and to area of sample of steel," page 196 "Effect of various atmospheric conditions of test," page 197 "Length of oil well tubing versus rate of attack," page 198 a table, "Effect of re-use of tubing," continued on page 199; page 200, "A comparison of freshly compared synthetic inhibited and with acid after storage"; page 201 "Effect of time and conditions of storage on rate of attack." In all I am reading you now there is no mention of time in your report Exhibits 184 and 185. A. Well, that is the reason, as I told you before, we wanted to get a laboratory test that would give us comparable figures for that large scale test and so we studied some of these factors that were different in the large scale tests from the small scale in order to get such a test, and we found for example that if you took a one inch collar of tube you got a substantial result, but when you took a three inch collar it went up for the last six inches in length, which was about as large as we figured we could go.

The time of contact had an effect on the percentage of inhibition, and one of the major factors, however, was this cutting of a small piece of steel, cutting and getting so much of an edge, that metal that has been worked very strenuously is different, and the final results are that test that we described, all this work, and to put in all those details, we didn't feel it was worth while. We tried to verify these reports to bring out the major factors involved.

Mr. Owen: Well, I will state in that connection, Your Honor, that these reports were not prepared with the idea they were going to be offered in evidence.

The Court: I understand. They are documents we are prying into for the purpose I indicated.

Mr. Lyon: Before we commence with the next run

entered in DX-190, I want to stop and ask you about a comparison that I note between this run I, which you did not report, with run H, which you reported under the number 2-M, and run A, which you did not report. I note that this run I, which I am interested in, that the conditions as stated at page 105 show that that was a synthetic acid, an acid made up of adding the copper and lead, and that you added about 4 parts per million of copper and 225 parts per million of lead. A. Does it state that I added 4 parts per million of copper?

Q. That is the figure that we get out of here, if it is any— A. (Interrupting): Does it state that?

Q. It says 15 per cent HCl acid, containing 2 $PbCl_2$, and $CuCl_2$, so the composition of acid is similar to that in run H, and run H gave about 4 parts of copper and 225 of lead? A. Similar is not identical.

Q. Now, then, in that test you would have a synthetic Menaul tank acid, run down the pipe, isn't that correct? A. We would have a synthetic acid of whatever concentration we had there.

Q. And run down the pipe. There would be no tank with the lead plate in it? A. No.

Q. And the connection to the pipe? A. No.

Q. Whereas in run H, which became 2-M, you did have the tank and the battery to produce the tank acid, and you ran that acid down the tank with the connection, with the so-called tank connected pipe—isn't that so? A. I believe so.

Q. Now, as reported here in this run I, which had no connection between the pipe and the tank with a battery in it, you found that in the—that during the progress of the acid down the pipe, the acid removed 670 grams of iron; whereas, in the comparable test H, which you reported as 2-N, where there was a connection between the tank with the battery, or the lead plate as the battery, and the pipe, the loss of iron, or the removal of iron in the pipe was 265 grams? A. That number 670 you have on a slip of paper there—you did not get that out of the report?

Q. Well, I have it here in a calculation that we have made. A. Oh, but I am very certain it is wrong, that calculation.

Q. Will you tell me, according to the results as you have them reported here, and calculate it, if necessary, the amount of iron in grams that were removed from the pipe, in the passage of the acid down the pipe in run I, which you did not report? A. I told you that I would have to have the book for some little time to make that calculation, and you wouldn't give me the book over noon.

Q. I am going to ask you to make that calculation, because if that is the correct amount of iron that was removed in run I, or approximately the amount, as compared with the amount of 265 grams, which is reported in Exhibit PX-185 as 265, the result obtained in run I in that respect is entirely contrary to the conclusion that you drew and reported in Exhibit PX-185? A. This morning I went into quite a lengthy explanation of why we discarded run I. And the run did not duplicate this other run. And the acid as prepared ready to run into the tubing had a very low inhibition measured in laboratory test and the acid run in the other run had a higher inhibition, almost twice as great.

Q. Now, why did you say you discarded run I? A. Because the effluent acid from run I was extremely low in copper, and we have definite reasons for believing that some mistake was made in the copper addition in that particular run.

Q. We are not interested in the copper addition. We are interested in the comparison of the amount of iron that was removed in the passage of the acid down the pipe. A. Wait. You have got to compare that when you are talking about iron removal, because there is a tie in between copper and inhibition.

Q. How much copper did you determine to be in the acid as you prepared it in the crock? A. I explained to you that we ran the sample and, as I recall it, the parts per million came out to be 4.

Q. Yes. A. That is about as I recall what we were

aiming at. Then the sample of the effluent acid came out to be about 1.3 or 1, and then the inhibition tests of the original acid showed about 16 per cent inhibition on this small scale test, whereas the synthetic acid that contained three or four parts per million of copper all ran 30 or 40 per cent inhibition, so—that is, on the small scale tests, and therefore we knew that something was wrong.

Now, it seems when we got all the figures together, we had no more of this original sample of acid and we couldn't go back and run the copper, but there was three things completely wrong with the sample, and this figure that we got, and the figure that we will give you is 471 grams of iron dissolved in that run, which is the corrected figure, still shows 50 per cent inhibition, and that is what one would expect if you had about one and a half parts per million of copper there.

In other words, the iron loss agreed with the concentration we found in the effluent acid and with the per cent of inhibition that we found in our laboratory test on the original acid, indicating that there was something wrong with that acid.

The Court: Let me see if I understand your statement. I got this notion, that acid in H was made by the lead plate in the system that you thought was comparable to the transportation tank. Is that right? A. That is correct.

The Court: I thought that H, after you had treated it in the way you thought was comparable to the transportation tank, that you did analyze it and find out what it contained. A. Yes.

The Court: The thing you prepared was I, synthetically, as you thought, to put in those same ingredients that by analysis you had found in H. A. That is correct. We thought we had put them in.

The Court: Well, now, wouldn't the natural conclusion of that be, of two treated in that way, that you would be more positive about what was in I than you would in H? What I was thinking was that the only way I can be wrong

—not the ego I, but the letter I—could be wrong would be by an actual mistake in making the synthetic? A. Yes.

The Court: While in H there is the opportunity always present in an analysis of not getting everything into it just right. I think of the two, in other words, if I was making up a batch of water and salt and sugar, and I took so much water and so much sugar and so much salt and put them into the thing, I would be more sure about what was in there than I would if somebody handed me some water and salt and sugar which they had mixed up and I went into the laboratory and analyzed it. Maybe my logic is poor there. A. Well, it is difficult to tell the different degrees of reasonableness, except that there are three or four factors here which enter into indicating that a mistake in weighing of the copper, or some factor like that actually occurred.

Q. (By Mr. Lyon): The copper was actually weighed out that was put into that in I? A. Yes.

Q. And you did analyze the acid after you made it up? A. Yes.

Q. And determined actually by that analysis that there was the four parts per million of copper present, did you not? Did you get my question, Doctor? A. I did not. I was looking for something here.

Q. I say after weighing out the amount of acid in accordance with what you found you needed, I mean after weighing out the amount of copper in accordance with what you determined would be necessary to add to correspond to the acid produced in run H, you did actually add that copper to the acid, and then after the addition and the acid was made up, you analyzed the acid and found by the analysis that there were 4 parts per million of copper present in the acid, as shown by your records, isn't that true? A. I have to refer to these records that I have to see exactly what was done, and after I do that I will answer the question. The runs that we are comparing are H and I. H is 2-N. April 13, 1940. In 2-N the parts per million of copper is 2.88, and the amount of copper that actually was added to the acid in run I is about 2.4 parts per million of copper.

The Court: Now what was H? A. H is 2.88 parts per million found by analysis. Added 2.4 and it was about two-tenths of a part per million of copper in most of these acids. I don't recall the exact number for that batch of acid, but that brought it up fairly close to the 2.88. Now, that is what was recorded in the book as having been made. The figure that was found by analysis was 4 parts per million in that acid, which on the face of it definitely indicates some mistake was made in the analysis.

The Court: How about this for the mistake, that there was something in H on your analysis you hadn't found that does this extra trick, how about that for a reasonable conclusion? A. That in H that there was something else?

The Court: There was some ingredient that you haven't yet found and don't know anything about that does this trick of the difference? A. I don't believe that that is the case.

The Court: What is there to disprove that? Wouldn't that be—if you didn't make any mistake in either one that would be a logical conclusion, wouldn't it? A. If there is absolutely no mistake made.

The Court: Yes. Then your conclusion would be that there was something in that H that you hadn't analyzed for, hadn't found. I don't know, maybe something, X, Y, Z. A. I believe that would be fairly logical, yes.

The Court: I don't know whether that is a logical conclusion or not. A. But it is one of the things that you have got to consider. First, the fact that 4 parts per million were found, and there was only 2.6 parts per million which was in there, if the man had weighed out the chemicals correctly, indicating that he made some mistake in that analysis.

The Court: I don't believe I have got that line of reasoning, Doctor. Give it to me again. A. The amount of copper chloride that was weighed out corresponds to an amount that would increase the copper content by 2.4 parts per million.

The Court: In other words, if you made no mistake

now you had the same amount of copper in both of these? A. About 2.6 compared to 2.88, or something like that, very close, if there was no mistake.

The Court: As I understand, you were making them as near alike as you could? A. Yes. And in the analysis the one sample I that was analyzed showed 4 parts per million. That was taken at the inlet of the tank in the run. That is out of the crock. This is a crock run in I. That sample showed 4 parts per million of copper, which is evidently higher than it could possibly have been unless some sort of a mistake was made some place. Then the analysis of the effluent acid leaving the piping system showed about 1½ parts per million, the copper solution leaving the pipe—about 4 samples of that were analyzed, and they all showed about 1½ parts per million of copper.

The Court: How long after you put this copper into that before you analyzed it and got the 4 parts per million? A. I don't recall the time.

The Court: I mean the one you made synthetically and you had it in what at the time? A. In a stone crock.

The Court: And you put in your copper, and then you analyzed it. You put in what would take it up to 2.88, and then analyzed it and had 4. A. Yes, that was what the analysis showed.

The Court: Now, how long intervened? A. Not a great deal of time. It was probably the same day, the same day the materials were put into the tank. And that is the figure that we question and we cannot check because we ran the inhibition of that sample and it showed an inhibition that would correspond to about 1½ parts per million of copper.

The Court: One and one-half? A. Yes.

The Court: Not four. A. No.

The Court: Nor not the 2.88. A. No. Something went wrong I cannot explain.

The Court: You think you made two mistakes, then? A. Everything except the four, yes. Two mistakes. I think that is possible.

The Court: You think out of the four two of them must have been wrong? A. No.

The Court: Well, now, there were only three places for mistakes, as I understand. One putting in this 2.88, or what would bring it up, the other analyzing it and finding the 4, and the other is the amount of iron that it ate. Two of those must be wrong. A. Two of those three, but there is this inhibition of the original acid which checked the 1½ parts per million of copper. We ran the inhibition of that original acid in the laboratory test, and that agreed with—

The Court: That analysis— A. That is, the acid that we took out of the crock. It attacked the steel in the laboratory test and it did not show as great an amount of inhibition as it should have if it had the 2.88 parts per million of copper in it. You see, we ran not only the analysis of the inlet acid but ran the inhibition of the laboratory acid.

The Court: Now, did you run an analysis of the commercial acid you bought? A. Yes.

The Court: Then you got four. How are you going to help those two mistakes? One is either you were wrong in analyzing the commercial acid or you were wrong in the amount of copper you put into the commercial acid, or you were wrong in the analysis after the 2.88 had been added together in that analysis, or you were wrong in your weights when you figured out that it had had a loss of 640 grams in the pipe. Now, is there any other place where there might have been an error? A. Well, let's go through them again. First, the analysis of the raw acid. The second is the weighing out of the copper.

The Court: That you put in with it to bring it up to 2.88. (Witness continuing): The third is the analysis of the inlet solution for copper.

The Court: Which means the solution after you had put the two together, put the copper in. A. Yes, sir.

The Court: The fourth is the testing of the inlet solution for inhibition in the laboratory test to test how effectively it was inhibited in the laboratory tests, a check on

its composition. That is what I referred to, as being on the tubing. A. Oh, no, that was just a little sample.

The Court: That is a laboratory test. Then we have the increase in iron content in acid running through the tube. All right. Now, then, the fifth? A. That was the fifth. Then we have the loss in weight in the tubing, sixth.

The Court: Sixth? Then the fifth I did not get. I thought that was the loss in weight. A. That is figured from the increase in iron content from our solution; that is, we determine the iron accurately by finding out how much iron was dissolved by the acid.

The Court: In solution? A. In passing through.

The Court: That is, how much of it was lost, in weight? A. How much the loss in weight was.

The Court: Now, you have got six. How many of the six must be wrong? A. I think probably two.

The Court: Two of the six? A. Yes, sir.

The Court: Have you any choice as between where they are most likely to make a mistake? A. The most likely—it is difficult to say, but it seems as though the weighing out of the copper would be the one least likely probable, and yet I think that is the one that probably is the thing that is wrong.

The Court: It seems like the least likely one? A. It seems like the least likely one to make.

The Court: Now, you have got to make another one. What is that other one? A. The analysis of the inlet acid, and the weighing out of the copper.

The Court: That is the other step that is one of the two? A. Yes.

The Court: Why have you reached that conclusion? You have picked for your first choice the one that you would be least likely to make? A. Yes.

The Court: Why have you done that? A. Because all four factors, other than those two, point definitely in the same direction. First, the effluent acid shows 1½ parts per million of copper. The inhibition that we determined on the laboratory test on the inlet acid gave an inhibition

corresponding to 1½ parts per million of copper. The loss in weight of iron of the tubing, the loss in weight of the iron in the acid both pointed towards that performance in the acid, which is about 1½ parts per million of copper.

The Court: Has there been any effort made to repeat? You couldn't get the same thing, but repeat in a similar way this experiment, and see how it would come out? A. Yes; we have two repeats on it, F and J. Run J is the repeat of this particular run and is reported in the report as 2-B. Run 1-B and run 2-B both are duplicates of this type of test.

The Court: Well, 1-B is F, isn't it? A. 1-B is F.

The Court: And what is the other one? A. The other one is 2-B. Run J.

The Court: 2-B. 2-B was not reported. A. Oh, yes. 2-B was reported.

Mr. Lyon: You mean 2-B in the new series? A. 2-B in the new series.

The Court: Now, then, you have run how many checks— A. (interposing): There are two checks on it.

The Court: You have run two checks one way and one check the other, then. A. We run two checks that we reported here.

The Court: You have run three checks or two in this method? A. Three in this method, yes. 1-B, 2-B, and the one not reported, but—

The Court (interposing): You have just got a fair majority. A. No, we have eight to one, nine to one.

The Court: But that is other reports. That is other methods? A. No, by running directly from the crock we have shown that iron makes practically no difference in the tests.

The Court: As I understand you, 2-B and 1-B are identical with those? A. Crock acid.

The Court: With the one that was not reported. A. With the Menaul.

The Court: In other words, I have been figuring them here, F and J were identical with I, and I am not taking

your new series. I am taking the old. A. F and J are identical with I.

The Court: F and J are identical with I. A. They have the same amount of lead, about 3 parts per million of copper, and they have 1300 or more parts of iron, quite a high iron content such as we got out of our Menaul tank, but we have two other runs that are in here, in which we prepared synthetic acids duplicating the analyses that Dr. Bartell turned over to us from the defendant's field tank samples, that have about the same copper and about the same lead, but the iron is somewhat lower, so there are four running from the crock with synthetic acid. Now, even if we take this run I and throw it in, it doesn't make a great deal of difference as we see it, and I would be just as willing to do that, if we say—

The Court (interposing): There is so much difference that I was — A. (interposing): No, the difference—

The Court (interposing): Don't you think that if we ran—I am not asking that it be done—a hundred times, you get 95 of them that would run along pretty close together, probably? A. I do not think you can check extremely closely. We have quite a bit of evidence on this I that something went wrong, and the weight loss is not the figure that Mr. Lyon gave to you. He gave you a figure he figured out erroneously, and not the figure we have given. The figure we have is 471 grams of iron lost, which is over 50 per cent inhibition in this run I, over 50 per cent inhibition in run I.

The Court: Which one of you are right? One of you is wrong. A. That is what I am supposed to provide proof to Mr. Lyon on when I can get that data book.

The Court: One of you simply make a mistake. A. So I wouldn't object to throwing that in as another run.

The Court: I am nof looking for an average. I am looking for the right. A. Yes. I did not feel that that was a run that would cause me to question seriously that something radically was wrong with our tests; that something happened on that particular run. Just what it was I can't explain.

The Court: As I now understand it, you have three others that you think are comparable with this method? A. We have four others.

The Court: F and J and what are the others? A. We have 2-D.

Mr. Owen: What is the original number? A. Run N and run Q.

The Court: O, P, Q. All right. Q you think is comparable with this? A. Yes.

The Court: And what other ones? Now, I have got as comparable F, J, Q and M. A. And I also feel that the runs using the Menaul tank where no wire was connected are also comparable, where there was no electrical contact that could possibly be exerted, and the composition of the acids run through there are comparable. The stoneware crock did not exert an effect and the tank when it was electrically disconnected could not exert any effect. So I would say there are at least six tests that are comparable with this run I, and run I, there are two-thirds of the facts which indicate something wrong, and even if you throw the thing in and say, well, assume that you weighed it out right—

The Court (interposing): That part doesn't interest me. I was interested in seeing whether it was in error, and I agree with you that I can't make it now, with the light I have, I can't explain it on any theory except that there has been a mistake somewhere? A. That was our belief, and that is why we did not include it.

Mr. Lyon: Even under your figures where the amount of iron eaten off the pipe in run I, to-wit,—what is the figure as you gave it? A. 471 grams.

Q. As compared with 265 grams in run H, run I is contrary to the conclusions that you reported in your reports, PX-184 and 185? A. It is somewhat off, I will admit that frankly.

Q. And the results of run I in that comparison would be favorable to the defendant in this case? If it was an error, it was an error in the defendant's favor, and not in the plaintiff's favor, that is true, isn't it? A. If we

had not found these four or five facts that indicated that an error had been made, then I would have seriously questioned all of the work that we had done.

Q. But that isn't the question I asked you, Doctor? A. Will you repeat the question?

Q. I asked you if there was an error, it was an error in the defendant's favor, and not the plaintiff's? A. That would be correct.

Q. Which has been true of each and everything that you have excluded on your own explanations today. Every time you made an exclusion that we have discussed, the error, or the point which you objected to, was always in the defendant's favor, isn't that true? A. I don't believe that is true.

Q. Mention one of the things that you excluded because it was in the plaintiff's favor. A. I can't recall all the things we discussed, but the reason for doing these things was to present a simple and concise picture of this in a practical manner, of these inhibiting effects of these metals, and not cluttering up of any report or dragging in millions of numbers to becloud the picture, is the thing that I did not want to do there. I have freely testified when asked for information about any of these tests, as to what our motives and what results we got, and so forth, and I have not hidden any errors that we made.

Q. You haven't answered the question yet. You have argued about it. A. I don't believe that all of the things we have dropped were favorable to the defendant.

Q. Can you name one that was favorable to the plaintiff? A. I don't recall.

Q. Well, now, let us go on. Commencing at page 218 we have the next run, which was run O, dated May 1, 1921. This covers pages 218 to 221 of Exhibit DX-190. It says, as to equipment, the same as had been used in run K. The tubing had been previously used in runs D, H, I, J, K, M and N. That means the same tubing that you—that you used the same tubing in all those runs, is that correct? A. Yes, that is correct.

Q. The conditions of the test are stated as follows: (Reading): "The tubing system was filled with crude oil. The oil was then drained, and the system sealed. Approximately 24 hours later the seals were broken, and the oil that had collected in the bottom section was removed. The run was started. The 15 per cent hydrochloric acid was passed directly through the tubing system from the stoneware crock at one gallon per minute at 85 degrees F."

I think that I brought out on cross examination that you had made this run, but you did not mention it in Exhibits PX-184 and 185? A. I believe it was brought out on direct examination.

Q. But it was not mentioned in your reports that are offered here in evidence? A. No, because the reports did not touch on oil.

Q. Well, now, I think you stated, or gave a figure based on this test as to the extent to which the oil tended to reduce the rate of corrosion. Now, what was that figure, Dr. Prutton? A. As I recall it, it was around 60 per cent, or 70, somewhere in there.

Q. How many? A. 60 per cent.

Q. Then it is probable, is it not, that if the acid were being fed through the pipe at a very different rate of speed, say six or seven or ten times as fast as you were feeding the acid through there, that the oil would have affected the amount of corrosion in some other figure, is that right? A. Well, the rate of speed would have something to do with the attack, and the amount of wiping off of the oil from the surface; but the inclination of the pipe would have a considerable bearing on just how it would wipe it off.

Q. Did you make any tests with the pipe upright? A. No, we did not.

Q. To determine what the effect of oil on the pipe would be? A. We made tests, in our laboratory tests, which was the—the tubing was practically in a vertical condition. It was the same pipe sections in the laboratory tests.

Q. Did you flow the acid through a vertical pipe that

had been oiled? A. No, I say we did not do that. We could not do it.

Q. Did you make any other tests except at this rate of one gallon per minute, I mean, where you had it at say, the rate of 750 gallons an hour, to see what the effect of the oil would be? A. No, we did not.

Q. Now, the next run in this book begins at page 222, and is run P, dated May 11, 1941, and the equipment is stated as follows, the same as had been used in run K; the tubing had been previously used in runs D, H, I, J, K, M and N and O. That is correct, is it not? A. I believe so, if you are reading from the book.

Q. The conditions of the test are stated on page 223. (Reading): "Before removing, each section of tubing was filled with crude oil and allowed to drain for at least twenty minutes, and then the section was assembled and the run started. Half of the acid was passed through the system very rapidly, and the remaining was passed at one gallon per minute, at 85 degrees F."

Did you get any values to show what difference it made in the rate of corrosion when the acid was being passed through the tubing quickly, as compared with a flow at one gallon per minute? A. Well, at this rapid rate. I don't recall the rapid rate. Do you recall that, Mr. Lightfoot?

Mr. Lightfoot: No, I do not.

(Witness continuing): It is in the book?

Mr. Lyon: I can't find it.

(Witness continuing): It was a very preliminary run and I don't know the rate that was used.

Q. I notice at the end of this under Mr. Lightfoot's signature, with his initials (I don't know whether he wrote it or not) page 225, the following note: "Comparison to other test invalid because of ratio of acid flow used in this test." Did you write that, Mr. Lightfoot?

Mr. Lightfoot: Yes, I did.

Q. Well, I take it from that, that comparisons of these tests are not valid, the results of these tests are not valid, where you have a marked difference in the rate of

acid flow, is that correct? A. They are sort of mixed up. The test, some of the acids run through fast, so slow, and it was sort of seeing whether we could get any figures out of this equipment at all.

Q. I take it from that note you arrived at the conclusion if there was a change in the rate of flow of the acid, that you could not then validly compare the results of the tests, is that correct? A. I think that comment was largely dictated by the fact that we feel that these tests we couldn't compare a test running acid through at 5 gallons per minute through the same tube as we could with one going one gallon per minute. That test was run with this mixed up rate of flow and therefore we didn't feel you could compare these figures with any of our one-gallon per minute runs.

The Court: Would the corrosion be greater when it ran rapidly? A. I don't know that that would be true. It should be greater. The amount of iron should be greater.

The Court: I say that that is the reason. What other reason? A. That is all, and the peculiar flow conditions of this oil that is in there.

The Court: Wasn't it all comparable except the speed? A. The speed and the inclination of the pipe which permits the oil to run up on the top surface of the pipe, whereas in a vertical pipe you have a different—

The Court (interrupting): All three of these were in the same position, weren't they? A. They were in this horizontal, practically, pipe.

The Court: As I understood it, I understood the three tests were all just exactly alike except the one you discarded had a different speed in it than the other. A. No, these are not the same kind of tests we ran before. These are the ones we ran the oil in.

The Court: How many oil? A. Only two oils.

The Court: How many did you save? A. Didn't save any. We reported the general results here in direct testimony but we didn't prepare a table of them because we didn't feel in almost a horizontal tube you get the same—

The Court (interrupting): But you treated all of those exactly alike. A. Exactly alike. It showed a reduction in iron.

The Court: As I understand there are figures that show the results, why you didn't report it, but do I understand in this book he is looking at there are figures about all of them? A. About the two runs.

The Court: And then there is one that you haven't got the figures for? A. No.

The Court: How many runs are shown there? A. Just two oil runs and all the data is there. I gave on direct testimony the general results of that test.

The Court: But I am talking about the figures in that book. There are figures there for both of them? A. Complete.

The Court: You haven't treated one any differently than the other? A. I just made a general statement. We didn't figure out the results of the test.

Mr. Lyon: There is a note at the bottom of the second run P "Comparison to other tests invalid because of the ratio of acid flow used in this test."

The Court: Now, does that apply to both of them? A. No, only to one.

The Court: Now, the only difference there and the reason you think that cannot be used is because of this difference in the flow, that part of the time it went faster than the other? A. No, that is not the entire story.

The Court: What is there in there that that should be discarded any more than the other? A. I don't think any of them should be discarded.

The Court: But you made the note. A. Making the note implies a comparison of a run in which we use 5′ per second flow. Every other one was run at 5′ per second.

The Court (interposing): Now, the conclusion I get as to why that one is less valuable than the other, do you think that one is less valuable than the other? A. I think neither one of them have any great significance, and that is what I testified.

The Court: Well, if there is any difference in value as between one and the other that I can see, it is because one ran at two different speeds and the idea is that a different speed makes a difference in the amount of corrosion. A. Yes.

The Court: That is the only explanation I get. A. Yes.

The Court: And this difference is that the faster it runs the more it eats. A. That is right.

Mr. Lyon: Now, just on that point, when you say the faster it runs the more it corrodes or eats the iron, you don't mean to say that if you are measuring the amount of iron in a gallon of the acid after it had gone through the pipe you would find a higher percentage? A. No. We discussed that.

The Court: I am talking about a measure of time. I am saying in an hour, as I understand, if the acid runs by at a rapid rate it eats more in an hour. A. Yes.

The Court: Than it does if it runs by at a slow rate, but I did not get the idea that if it ran by rapidly the gallon, one gallon, would eat more. In fact, if I was going to guess about it I would guess it would eat less. A. That is exactly what it shows.

The Court: Because it would have less time, that particular gallon, would have less time for its lunch.

Mr. Lyon: Did you make comparable tests of that kind and record them in this book, PX-190? A. There are some figures of iron content of the acid leaving the system, and I think it shows that, in this first part of the run, where it ran through fast, there was, oh, .2 milligrams of iron per cubic centimeter, and when it slowed up to one foot per second, why, there was .4, showing that the concentration of iron in the acid was lower, but I am quite sure that the total amount of iron dissolved was greater. We did not calculate that or measure it. We couldn't tell.

Q. That is what I want to know. You say you are sure about that. I haven't found any test of that kind in this book, if there is one. A. Here is the reasoning—

Q. (interposing): I am not asking about the reasoning. Have you actually got any tests in this book showing the total amount of corrosion in a given length of pipe if you pass different amounts of acid through it in the same length of time? A. No, I don't think we have the data. Mr. Lightfoot, do you know the rate we ran that through? Was that five gallons a minute or something like that?

Mr. Lightfoot: No, the first part of this run—

Q. (interposing): You don't know how fast that was, exactly?

Mr. Lightfoot: As fast as we could handle it conveniently. A. You don't know how fast that was? It was more than two gallons?

Mr. Lightfoot: Yes.

A. More than two gallons a minute. Just from his visual observation, it was more than two gallons a minute for the acid going through the pipe. The acid through at one foot a second picked up .4 milligrams per gallon and going through at that fast rate, faster than two gallons a minute, it picked up .2. It would be quite a good rate.

Q. Do you find those figures here? A. I say it isn't in the book and I can't prove it. As I explained before, those runs were simply runs made to see what would happen and see what kind of flow conditions would be obtained.

The Court: Can you tell me, Doctor, we have got two things to conjure with, that is the amount of acid passing over the iron, and we have got the length of time? Now, I understand that everybody is agreed, if not, I wish everybody would stop me in my thought, I understand that you are agreed that the longer the time to which a surface of iron is exposed, the greater the amount of corrosion? A. Yes.

The Court: And it is practically directly proportionate? A. Apprpximately.

The Court: Ignoring the speed is uniform now? A. Yes.

The Court: That is, it is pretty near in proportion to

the length of time, directly in proportion. Now, I do understand that you are also pretty well agreed that iron exposed for the same length of time at a speed of one gallon per hour, the corrosion is less than it would be if it was exposed twenty gallons per hour? A. That would be my contention, but—

The Court: I understand you. A. That is my belief.

The Court: I understand you and Mr. Bartell to say that? A. Yes.

The Court: Is there any question about it, or is that something discovered since, or is it well known? A. I think that is well known by practically every one in the acid treating business.

The Court: Now, we get down to a point, and I take it nobody yet has told me, and it is not so easy to see how the relation of the amount of corrosion compares to the speed. I am satisfied that it is not in direct proportion to that. I feel no hesitancy in saying I have got the notion that because it would eat a certain amount in an hour going at the rate of one gallon an hour, and you put it up to two gallons, I am sure it wouldn't eat twice as much, but can you tell me anything about that? Is there any mathematical figure of relation or proportion? A. I can't tell you any definite relationship. I think some of the men that run these inhibitions possibly could tell you, give you some better information.

The Court: You don't know of any scientific figures to enlighten us about that? A. No, I don't.

The Court: All right. I can see that is a more debatable and a more difficult question than the other. All right.

Mr. Lyon: The next experiment is entered in the Exhibit DX-190, commencing at page 227 and is entitled "Pressure corrosion test." The data on this seems to continue over and is concluded on page 231, signed by Mr. Lightfoot. You have already told us that you found pressure didn't make much difference? A. No. It makes a little difference, but it reduces everything in the same amount somewhat.

Q. All right. Now, the next run or the next entry in DX-190 commences at page 232 and is entitled "Run Q, June 24, 1941." The statement as to the equipment is as follows: "Same as has been used in run M, tubing had been previously used in runs D, H, I, J, K, M and N, O, and P." There seems to be no remarks on the condition.

The Court: That pressure one is what? A. That is the oil one.

Mr. Lyon: That is the second oil one. There were two oil runs, O and P.

The Court: All right.

Mr. Lyon: Now, there don't seem to be any remarks here about the conditions in this treatment, but this treatment Q is the one which was reported as 2-E in Exhibit 184, 2-E, that is correct, is it not? A. Yes. On page 237 the conditions of this test are stated.

Q. I was in error in my previous statement when I said there were no conditions given for this test. The conditions are on page 237 of the exhibit, and they read: (Reading): "4.465 NHCl acid treated with $FeCl_2$, 4 H_2O and $PbCl_2$ and $CuCl_2$, to be passed from the stoneware crock at one gallon per minute and 85 degrees F. through the tubing system." A. That is correct.

Q. I notice something that may have some significance here, in reporting how the copper was added in some of these other tests, copper chloride is indicated, whereas here the formula Cu_2Cl_2, which is cuprous chloride— A. There is cuprous chloride and cupric chloride. As I recall in some runs we used cupric, and then towards the end we used cuprous.

Q. Does that make any difference? A. The effect is immaterial in that the amount of metallic copper that is in there—the only thing that could happen would be that this cuprous—the cupric chloride would react with the iron pipe and would be reduced.

The Court: And you put that in by weight? A. By weight, yes, and you then figure the copper content.

The Court: I see. A. The reason we changed over

from one chloride to the other, and it would have absolutely no effect whether it is cuprous or cupric, the reason we changed over was that the cupric chloride, as you purchase it it is labelled $2H_2O$—it is in the form of crystals, in bottles, and seems to be partially dehydrated, and we did not feel that we could count that as well as the cuprous chloride, which is anhydrous.

The Court: But you take, say, a pound of cuprous chloride, just the same as you take a pound of the other? A. Yes. We chose the cuprous chloride because that comes in an anhydrous form, and the cupric came in a dehydrated form, and the crystals of it seemed to be partially dry, which would indicate it was not quite the pure hydrate, so we thought it would be more advisable to use the cuprous. There is no possible change that it can make in the test.

Q. In the title data on page 237 there is the following notation:

(Reading): "To 192 gallons of 4.465 NHCl, 420 grams of $PbCl_2$, 3.97 grams of Cu_2Cl_2 were added."

The Court: And that is what? A. Cuprous chloride.

Q. The second has twice as much copper in each molecule as the first? A. I don't think it is twice as much—I mean, atomically it is, but by weight—in other words, there are two atoms of chlorine to one atom of copper, and one atom of copper to two atoms of chlorine in cupric.

Q. Well, what I mean is there are twice as many atoms of copper in the second as the first? A. Oh, yes.

Q. This run Q was reported as run 2-E. We may already have covered that, but I say that to make it clear. A. Yes.

Q. Following the write up of run Q, commencing at page 240, we find various data recorded commencing with a title "Laboratory Tests on the Inhibiting Properties of Crude Oil on Oil Well Tubing in 15 Per Cent Hydrochloric Acid." And with notations on that subject. And then on page 245 we find the title "Study of rate of attack of hydrochloric acid on oil well tubing, small scale model, laboratory set up," with the title, "Sketch of Apparatus Used."

This apparatus shows two containers, each containing acid, and in each container a sample of tubing, one container sample of tubing is numbered A and the other is numbered B. And the tubings contain connection—are connected by a connecting wire outside of the two containers and extending across from one sample to the other, outside the acid, and then also connecting the two acids and extending to the two containers is a capillary glass tube, and then also connecting to the connecting wire previously mentioned, and the connection being outside the acid, but extending into the acid, is a lead sheet.

Now, will you tell me what you were trying to prove by that apparatus and whether you got any results out of it that proved anything? I see nothing about them in your reports. A. No. I told my assistant, Mr. Lightfoot, to see if we could fix up a demonstration that might be brought into court to demonstrate the fallacy of this Menaul process, and the difficulties experimentally that we encountered in getting the capillary full of acid, and so forth, and it just didn't work out very well, and we didn't even get protection over here of the oil well tubing with the lead, so it looked—the results would all indicate that it didn't protect any place. The things were so—it just didn't work. It was—

Q. (interposing): These tests or these recorded values that follow this, through to the title "Run Q Inhibitors" on page 252 were all the results of experiments on that attempted set up? A. Run Q?

Q. Up to where there is a title "Run Q Inhibitors—Inhibition." A. Oh, yes.

Q. If those are what they are about, I don't care to stop on them. A. No, there are some other things in between here.

Q. How far does that data go? A. It goes from here to here. There is 1, 2, 3 sides of a sheet. Is this included; is that part of it?

Mr. Lightfoot: Yes.

A. No, that is another thing, steel strip.

Mr. Lightfoot: Yes.

A. About two and a half sides of a sheet here discuss those crude attempts at trying to fix up a demonstration model to show that this thing wouldn't work.

Q. That is the end of page 247? A. Yes.

Q. All right. Then on page 248 we have a title "Demonstration Inhibition Test using Steel Strip alone and each steel strip coupled to a lead strip being bolted together above the surface of the acid and spaced about one inch apart in the acid." You remember that? A. Yes, that test was run, but I don't know how important it was considered, but when the Menaul patent was obtained they went into the Patent Office and had a lot of discussion with the Examiner, and the Examiner claimed that it wouldn't work, and then they proved that the potential is in the right direction, that it would work, and he still claimed it would not work, as I recall, so they got Dr. Gardner some place to run tests connecting the lead strip to a piece of steel and he showed you got 90, over 90 per cent inhibition.

Well, on the basis of that, they were awarded a patent. I think that was the determining point, because very shortly thereafter they were given a patent. And we were just checking up to see. We couldn't get hardly any inhibition at all. We got 20 or 30 per cent. If we had left the lead sheet in there for a length of time, for it to dissolve, maybe we could have got 90 per cent, but we did not check Dr. Gardiner's work.

Q. All right. Now, then, the next page, on page 249, it is entitled "Special inhibition tests using steel strips submitted by the Dow Company." What is that about? A. That was in connection with the pressure test work. I think we ran them outside the pressure bond and then inside the pressure bond, is that correct?

Mr. Lightfoot: Yes, that is right.

A. And I think these are outside. Are these outside?

Mr. Lightfoot: Those are outside.

A. At atmospheric pressure, and we used the same strips like the Dow Company used in their inhibition test.

Mr. Lyon: And then the next thing, on page 250, is a title, "Check on acid run O,"—I can't read that next word. A. Preliminary. In other words, that was a preliminary run.

Q. What was that about? A. That was one of those oil runs, wasn't it? Run O.

Q. Run O was one of the oil runs, but what was this check about? A. I don't know.

Mr. Lightfoot: That is the case where they checked the carboys for inhibition.

Mr. Lyon: And what did you find? Did you convert this to any per cent? A. After the run or before?

Mr. Lightfoot: Before the run.

Q. What did you find? Can you explain these results as to any per cent of inhibition, or reduction in corrosion? Mr. Lightfoot: That would have to be calculated.

Q. Was it calculated? Mr. Lightfoot: Well, it was calculated at the time. However, it is not entered in the book.

Q. Do you know what the results were, or have you got them at hand? Mr. Lightfoot: I can get them.

Q. All right. Either calculate them or find them. The next page is page 251, entitled "Inhibition of acid samples from old runs E, G, K, D, N, using crock composite and over-all end composite samples. Time, 3 hours, and 30 degrees C." Are these some more of those same laboratory charts with samples of metal and getting percentages of corrosion reduction that you have explained before? Mr. Lightfoot: Those are the large samples.

Q. The large samples. A. These are the end of the inlet acid of runs E, G, J, K, and M. Those are the blanks.

Q. These are the blanks again? A. They are laboratory tests that were run upon the inlet acid in the runs listed here.

Q. Were the results here incorporated or employed in the reports, Exhibits 184 and 185?

The Court: When you refer to blanks do you refer here to chemically pure acid or commercial acid? A. Commercial acids.

The Court: I think Dr. Bartell referred to chemically pure acid, and he referred to blanks. Here we are referring to blanks as commercial acid.

Q. That is correct, is it not? A. These are the commercial blank acids used in these particular runs, or the commercial acid diluted.

The Court: Just so we keep it straight. A. And the figures are not specifically listed in those reports, are they?

Mr. Lightfoot: I believe they are not.

A. I think in the testimony I gave some of this.

Q. As I understand, Doctor, at any time you made synthetic acid you analyzed your commercial acid and then you added to that whatever you wanted to? A. That is correct.

The Court: You never in any of your testimony or experiments dealt with chemically pure acid at all? A. We have used in our laboratory inhibition tests that I reported on, to study the effect of adding metals, we have used chemically pure acid to add metals in the laboratory tests.

The Court: Does your testimony show that? A. Yes, it clearly shows that.

The Court: All right. I am satisfied.

Q. Now, continuing the following pages up to the end of page 258, contains some similar work on inhibitions with lead and iron mixtures, and so forth. A. I don't recall what is in there.

Q. I come now to page 259, dated July 22, 1941, the day after this case started. The title is "The potentials across a lead sheet HCl and oil well tubing." What were these experiments, Doctor? A. They were checks on the Gardner affidavit that was used in obtaining the Menaul method and were to measure the difference in potential that occurred between a strip of lead and a piece of iron when put into hydrochloric acid.

Q. They were not checks across the lead sheet, hydrochloric acid, and the oil well tubing? A. Well, the piece of iron was the oil well tubing.

Q. Where was the lead sheet? A. Right in the same beaker with a piece of oil well tubing. In other words, we cut a strip, as I recall, out of a piece of oil well tubing, put a piece of lead into the beaker, and measured the voltage as it went across that little cell.

The Court: They were connected at one part? A. They were in a beaker like this (indicating) the top connected with a wire, the acid around it. That is the type of test Dr. Gardner reported.

Mr. Lyon: What was the purpose of this test? A. The purpose was more or less to see if we could duplicate Gardner's work. Somebody requested I do it, I think.

Q. Who requested it? A. I think Mr. Rebbeck.

The Court: Who is Gardner? A. A professor down in Oklahoma some place who made some tests and sent in a report of those in an affidavit to the Patent Office showing that this Menaul process would work. He made two tests in the laboratory.

The Court: And you were making these tests but while you were making these tests didn't that simulate according to your theory, the pipe when connected to the tank with the copper wire? A. It did not.

The Court: You say it didn't? A. Oh, no. Here we have a path of current that is direct and almost parallel; the pieces were almost together. It closely ties in with the condition they have where they have a lead plate in the bottom of the tank and a steel side, where the path is more direct.

The Court: In other words, the copper wire simply connected the two? A. That is right.

Mr. Lyon: Well, now, so we will understand your last statement, wouldn't the measurements of voltage in these tests reported here be somewhat comparable to the voltages you state you didn't measure in the Menaul tank? A. Well, if you will read those voltages, the voltage jumped quite a bit. In other words, it was variable, never very great.

Q. I am not asking that— A. Well, I can't answer in one word. I can't tell you exactly whether it is the same

voltage you get. I think it is in that order between the side of the tank and the lead plate, but not in regard—

Q. Mr. Lyon (interrupting): I am talking about what electrical pressure there actually is in a battery of the kind that we have in the Menaul tank. A. These figures are around a few hundredths.

Q. I am not asking you that. These figures would be comparable to the voltage or pressure in the Menaul tank? A. In between the side of the tank and the lead plate.

Q. These figures are comparable, isn't it true? A. I didn't say they were completely comparable. I said there was some general relation between them but I can't just tell you the general potential. If I may take the book and read the values. They skip all over.

Q. Well, first you determined the voltages with 4% hydrochloric acid, didn't you? A. Yes.

Q. Then next you determined the voltages with 7% hydrochloric acid, then with 10% hydrochloric acid, then with 16% hydrochloric acid, and then with 25% hydrochloric acid? A. That is right.

Q. Now, let's examine the voltages as you found them for 16% hydrochloric acid. You will remember you testified yesterday the voltage would not be as much as a tenth of a volt or .1½ volts. You testified to that, did you not? A. As I recall, I testified that we actually measured the potential between the tank and the tubing and it was on the order of millivolts, thousandths of a volt. The statement I made between the potential of the lead plate and the side of the tank I gave no exact figures but said it was on the order of a tenth of a volt.

Q. I thought you denied it could be on the order of a tenth of a volt. A. If I made that statement, I would correct it.

Q. All right. The figures, the voltages as you actually found them, as recorded on page 260 or Exhibit 190 for 16% hydrochloric acid, will you read them to the court? A. The figure is .18 volt.

The Court: Now, what is that? A. The voltage between a sheet of lead and a piece of steel.

The Court: These are all 16%? A. Yes. 18/100ths was the original voltage. As soon as it was connected it was 18/100ths. At the end of one minute it was 14/100ths. At the end of six minutes it was 15/100ths. At the end of nine minutes it was .158 volts.

Then a second run was made at 16 per cent.

The Court: You did the same thing over again? A. We did the same thing over again, with new strips. As soon as he could measure it it was two tenths of a volt. At the end of ten seconds, it was 11/100ths of a volt. At the end of one minute and ten seconds, it was 13/100ths of a volt. At the end of two minutes and ten seconds, it was 14/100ths of a volt. At the end of six minutes and ten seconds, it was 17/100ths of a volt.

The Court: This all had to do with 16 per cent hydrochloric acid? A. 16 per cent acid, yes. Now, if we go to the 10 per cent hydrochloric acid, the values are about .07 volts average. The values are—the values here were about .14, and so it is probable with 15 per cent it would be .12, or .13. The voltage changes with the acid concentration. And so the statement that it was about one-tenth of a volt—

The Court (interposing): Then it acts inversely—

A. (interrupting): The higher the acid concentration, the higher the voltage.

The Court: .08 is the average for 10 per cent acid. A. And for 16 per cent acid it is about .14. And so if we would calculate for 15 it would be around .13 of a volt.

The Court: Provided you follow these others out and you find them in direct proportion to the percentage and you do find them running upward. You have only given me two. A. I will give you the rest of them. At 4 per cent—

The Court (interposing): Have you the averages? A. Just by glancing at them I can tell you about the averages.

The Court: Give it. A. Four per cent hydrochloric acid, the average was about .04 volts. And with 7 per cent acid it was about .06. With 10 per cent, I gave you that, about .08. At 20 per cent the average is about .20, so it shows some progression.

The Court: That is voltage you are talking about. A. That is the actual voltage between the lead and the iron.

Mr. Lyon: When they are immersed in the acid? A. When they are immersed in this particular form of cell.

Q. The direction of that potential, or the pressure, the electrical pressure will be tending to force the flow from the lead to the iron? A. From the lead to the iron.

The Court: Tell me this, now, does this prove or disprove Professor Gardner's affidavit? A. The results are somewhat different than Gardner's affidavit, but they are in the same general direction, in this part of the work.

The Court: It doesn't tend to dispute it then? A. It doesn't tend to dispute it to any great degree. It is a matter of degree and not of difference. In other words, the current, this lead was negative with respect to the iron, by a definite voltage, which should tend to electrolytically protect the iron, and his conclusion on the voltage, we agree that the voltage is in the right direction.

The Court: Then it is corroborative of his, we will say. A. In general.

The Court: All right. A. But the inhibition that we ran was completely non-corroborative.

The Court: Is the Oklahoma professor going to be here at all?

Mr. Lyon: Professor Gardner is not, Your Honor.

The Court: All right. Let me ask another question. You say it disputes, or, rather, corroborates what he says about inhibition? A. About the voltage. About voltage but not inhibition.

The Court: Well, now, maybe I either misspoke or—it corroborates, rather than anything else, the voltages? A. It agrees in general with the voltage that he reported.

The Court: But you say it is disputed as to the inhibition resulting from that? A. That is correct.

The Court: Now, did he give his—I haven't seen that,—there are so many things here, I haven't that affidavit, but does he attempt to state there some claimed experiments? A. Yes.

The Court: Or does he state it from scientific opinion? A. Experiments. And we tried to duplicate those as close as we could. He reports from 90 to 97 per cent inhibition.

The Court: Did he tell how he did it? A. Not exactly. He told in a general way how he did it. He told the concentrations of acid.

The Court: Did he do it the best way or the worst way? A. We just took a way of doing it.

The Court: There are different ways of performing experiments. A. We just really didn't go into it to any degree at all. Because we got that one request to check this, and then the attorneys did not keep after us, so we dropped that.

Mr. Lyon: I would like to offer in evidence at this time a certified copy of the file wrapper of the Menaul patent on the defendant's Menaul tank system, No. 2,149,-617, so that I can read at this time Dr. Gardner's affidavit.

The Court: That is DX-191?

(The document above described was thereupon marked DX-191.)

Mr. Wiles: If the court please, we object to that. It is bringing in hearsay matter without any opportunity for us to cross examine. It is a self-serving declaration, where cross examination is peculiarly essential.

The Court: Not because it is proof of the thing stated, but in connection with the,—I take it all this comes out of cross examination, I take it that the witness now on the stand disputes the validity of that patent.

Mr. Wiles: Oh, no. Look, that is just the trouble with letting them go on a fishing expedition of this kind. At a certain time in this case we thought they might want to put Dr. Gardner on and prove this, and therefore we asked the witness to please make some investigations to see if Gardner is right. He gets it written down in a notebook. So far as that is concerned it hasn't anything to do with this case at all, I mean whether Gardner's affidavit to the Patent Office could be proved correct with regard to the

inhibition in their tank, didn't make any difference, that I know of here. Then they go and get this leave to look at our notes, and they find something that as yet isn't relevant here at all. Then they cross examine the witness and find in parts he disagrees with Gardner. Then they, having dragged out an entirely immaterial matter, they try to put in the file, and Gardner practically as a witness here, where we have no chance to cross examine him. Now, they have lugged in this stuff that hasn't anything to do with anything that the witness went into. We didn't intend to examine him about it, except possibly in rebuttal, or if they put Gardner on, or some equivalent man on the stand.

The Court: On what theory is that admissible? On what theory do you claim that is admissible?

Mr. Lyon: I claim it is admissible for two points. One, because the witness himself referred to it.

The Court: He only did on cross examination when you brought it up.

Mr. Lyon: I didn't bring it up, as a matter of fact. I think Your Honor was asking the witness some questions and it came out. A. I mentioned these tests we made were only preliminary tests.

Mr. Lyon: And he in his reports here, Exhibits 184 and 185, has mentioned this patent and disagreed with the patent and made some statements.

The Court: Those reports, are those the reports they put in evidence?

Mr. Lyon: Yes. They are the ones he put on through Exhibits 184 and 185.

The Court: I am going to go in now, if he is going—if you have attempted by direct proof to tear this patent you are talking about to pieces, why shouldn't I find out what that patent is about?

Mr. Wiles: All right: There are two things. There are two entirely different points. One of them is the Menaul inhibition of the tank, of the truck tank. The witness has said he thinks that works and adds some inhibition. We never questioned that at all, and that is what this

affidavit is about. Now, we say, and the witness has said that the claim of Menaul that by hitching up this little piece of iron he can inhibit down in the oil well, that that is just a plain fraud, and that isn't what this affidavit is about. The tests that the witness is now cross examined about, and that they are bringing this Gardner affidavit in, are those that relate to the inhibition within the tank. Now, we make those inhibitions in the tank and that is carried out in part by this lead plate.

The Court: Well, if I am going into that patent at all, I generally need to have the file wrapper here to know something about the patent. I will rule that that is not proof, that isn't proper proof for a defendant to bring in here, because the file and findings of the Patent Office, or somebody's affidavit, they are entitled to cross examine and know about. On the other hand, to the extent that you attack a patent, to that extent I feel I need to understand it and the theory on which it was, and all about it.

Mr. Wiles: For that limited purpose.

The Court: That is the purpose. I am not admitting the proof to dispute the document.

Mr. Lyon: I understand that. I agree with that.

The Court: I am not treating him as if he was a witness here. He is alive?

Mr. Lyon: Dr. Gardner? I never saw the man. I think he is alive.

The Court: Well, all right, I will assume that he is unless he is proven to be dead.

Mr. Lyon: I would like to read the affidavit, not as proof of the facts, but so that Your Honor may have it in mind, if you have any questions of this witness.

The Court: DX-191 is the file wrapper, and I am admitting it for an understanding of the patent, of the theory on which it was allowed, and the proper interpretation of the thing.

Mr. Lyon: The affidavit is entitled:

"In the United States Patent Office.

"In re Application of Paul L. Menaul.

"State of Oklahoma, County of ....., ss.

"F. T. Gardner, being duly sworn, deposes and says that he is a citizen of the United States, and a resident of Tulsa, State of Oklahoma; that he is Associate Professor of Chemistry at the University of Tulsa; that he has specialized in industrial chemistry and has made an intensive study of the question or problem of corrosion particularly in connection with oil field equipment.

"That his education has consisted of the following, and that he has obtained the following degrees:

"University of Oklahoma, 1 year.

"University of Illinois, 3 years, B.S.

"Cornell University, 3 years, Ph.D.

"That he has studied a copy of the application of Paul L. Menaul, Serial No. 116,786, filed December 19, 1936, for Method and Apparatus for Handling Acidic Solutions, and is familiar with the contents thereof; that he first obtained knowledge of the invention upon which a patent is sought in the aforesaid application on or about the 1st day of May, 1937, this having been called to his attention by the Ozark Chemical Company, subsequently by the Shell Petroleum Company; that both companies inquired as to whether this method and apparatus was operative, this information being desired by the Shell Petroleum Company in order to determine whether or not it was safe for them to use this method in the acidizing of their oil wells; that he made this investigation and determined that the method and apparatus were operative, and so reported to the Shell Petroleum Company.

"That officials of the Halliburton Oil Well Cementing Company, having learned of his research and experiments in connection with this invention, have requested that he study the application for patent referred to above and make this affidavit with respect to the said invention.

"That the operativeness of the invention may be clearly demonstrated by apparatus constructed as follows. The apparatus consists of strips of lead and steel immersed in a beaker of hydrochloric acid of known concentration as in Figure 1, Menaul 116,768"

Mr. Owen: Would Your Honor like to see that Menaul patent, and see the figure he is talking about? He is talking about Figure 1 there.

Mr. Lyon: That is right, of the patent as it finally issued.

The Court: That looks like I thought it would.

Mr. Lyon (reading): "said strips being not on closed circuit but connected by screw connectors to the wire terminals of the 'EMF' circuit of a Leeds & Northrup potentiometer having a sensitivity of .0002 volts, by means of which magnitude of voltage and direction of current flow were determined. The steel employed was a plain carbon steel of ap. .3% c. content. The lead was commercial sheet used for lining reaction chambers subject to action of dilute sulphuric acid."

The Court: What was the iron?

Mr. Lyon: The steel employed was a plain carbon steel.

Mr. Lyon (reading): "That he has conducted experiments with this apparatus at a temperature of ca. 30 degrees C. (86 degrees F.), and has obtained the following data on the voltages generated by the apparatus. In all cases the lead electrode was electronegative to the steel electrode; that is, oxidation or loss of electrons occurred at the lead electrode, while reduction or gain of electrons occurred at the steel electrode."

Then there is a table,

"%HCl by weight, and voltage."

"In all cases the lead electrode was electronegative to the steel electrode."

The Court: What do you think he means there?

Mr. Lyon: That means that the current would flow from the lead to the steel through the acid.

"3.50 per cent HCl," and the voltage was ".0455."

The Court: The voltage was what?

Mr. Lyon: At 3½ per cent hydrochloric acid, the voltage was at .0455.

The Court: That is comparable with what the doctor said.

Mr. Lyon: We have some more values. At 6.67 HCl the voltage was .0510.

The Court: And that is comparable.

Mr. Lyon: At 9.95 per cent HCl, the voltage was .0630.

The Court: Comparable.

Mr. Lyon: At 15.99 per cent HCl, the voltage was .0865.

The Court: We are getting off there.

The Witness: I said about a tenth of a volt, my figure was 12 or 13/100ths and is—

Mr. Lyon: It is .0865 on this table.

The Court: That is for what percentage HCl?

Mr. Lyon: That is for 15.99.

The Court: The doctor's is 14. There is quite a difference there.

Mr. Lyon: Yes, he is quite a little higher than this man, instead of lower.

The Court: Very much higher. That is the first place that they have been way apart. I would call that—maybe I am wrong in my yardstick, but I would call that, the others I look at as being—

The Witness (interrupting): That voltage is so low that two or three hundredths of a volt, Your Honor—I would say that those are practically check determinations.

The Court: Well, but there is a lot of difference where you put your decimal point. A. Oh, absolutely.

The Court: And his is a decimal and then a zero and then an eight. That is less. A. One-tenth.

The Court: And yours is over. A. Over one-tenth.

The Court: .14? A. That is true.

The Court: All right. A. But all I am saying is that voltage is small. You see, most galvanic cells, like a dry cell is 1.55 volts, and this voltage is only about one-tenth of a volt. This is practically nothing. Whether you consider one voltage or the other, we found, I would say that we agree with Dr. Gardner's voltage figures. That difference

in voltage, that slight difference is a few hundredths of a volt and it might be caused by a slight difference in the steel or the lead.

The Court: Yours is about twice as much. A. Yes.

Mr. Lyon: .14 and .086. A. It is almost twice.

The Court: Yours is almost twice as much.

Mr. Lyon: About two-thirds as much. A. Yours is about two-thirds of what we found.

Mr. Lyon: That is right. A. But I say both of them are negligible, in a galvanic sense.

Mr. Lyon: Then the affidavit continues:

"That he has conducted experiments to determine whether the corrosion of steel in hydrochloric acid is greater or less when connected to a lead plate as follows. Weighed steel electrodes as in the voltage experiments above were coupled with lead and immersed in hydrochloric acid solutions. After measured periods of time the steel strips were removed, wetted areas were measured, strips were washed, dried at 105° C., and weighed. The losses in weight (milligrams) per square centimeter of electrode area were computed. Companion steel strips not coupled to lead were subjected to the action of the same solutions for the same periods of time, and weight losses per unit area likewise computed. The percentage reduction in corrosion occasioned by coupling with lead was determined as follows:

$$\% \text{ corrosion reduction} = \frac{\text{mg./squ.cm.(coupled)} - \text{mg./squ. cm. (uncoupled)}}{\text{Mg./squ. cm. (uncoupled)}} \times 100.$$

"Data obtained in typical cases follow:

Then follows five columns headed "% HCl by weight," "Time hrs," "Loss of weight of steel mg./squ. cm. coupled to lead," "Loss of weight of steel mg./squ. cm. not coupled to lead," and "% reduction in corrosion due to coupling with lead."

I am only going to read the first column and the last column because the middle data is not needed here. For

13.47 hydrochloric acid, per cent reduction in corrosion due to the coupling with lead was 93.5. For 14.7 per cent hydrochloric acid, the per cent of reduction in corrosion due to coupling with lead was 97.0. For 13.7 hydrochloric acid—

The Court (interposing): That is right back where the first was.

Mr. Lyon: The first, the time for the first was six hours, the first two, both of them were six hours. Over a period of six hours.

The Court: All right.

Mr. Lyon: Now, the next two are for a period of eighteen hours, three times as long.

The Court: All right.

Mr. Lyon: The next item, 13.7 is 92.4 per cent reduction in corrosion due to coupling with lead. And the next item, 14.7 per cent hydrochloric acid shows 93.5 per cent reduction in corrosion due to coupling with lead. Then the affidavit continues:

"That the textbook of Inorganic Chemistry by Partington, published in 1927 by McMillan of New York, which gives the electromotive series of metals as listed by the examiner in the Office Action of August 16, 1938, is correct only under certain specified conditions and under other conditions the electromotive series there listed is not correct. The table listed is the table of 'normal electrode potentials.' The normal electrode potential is the potential exerted between a metal and its ions when the activity of the ions is unity. (See: Outline of Theoretical Chemistry, Getman and Daniels, 6th Edition, John Wiley and Sons, 1937, pages 429 and 430.) If the activity of the metal ion is decreased the electrode potential at the boundary between the metal and the solution of the ions becomes more electronegative (Loc. cit. page 439). There are numerous ways of decreasing ionic activity. One process causing profound decreases in ionic activity is the formation of a complex ion or molecule involving the metallic ion. The commercial cyanide process for gold recovery from low grade ores utilizes the change in electrode potential brought about by formation of a com-

plex ion from gold and cyanide ions. The normal electrode potential of gold is ca. 1.5 volts electropositive to hydrogen. In a solution containing an excess of cyanide ion, however, gold is electronegative to hydrogen. (See Cyaniding Gold and Silver Ores, Julian and Smart, Lippincott, 1907, Pages 69-72, incl.)

"The normal electrode potentials of zinc and copper are 1.1059 volts apart. Upon addition of an excess of cyanide ion to a solution of zinc and cupric ions the resultant electrode potentials of the two metals against the solution are of the same numerical order due to complex formation, making possible simultaneous discharge of the two metals from solution in commercial electroplating of brass. (See Applied Electrochemistry, Allmand and Effingham, Longmans Green, Second Edition, 1924, page 358.)

"Authorities are in agreement that a complex of some type is formed when lead reacts with hydrochloric acid. (See Mellor, A Comprehensive Treatise of Inorganic and Theoretical Chemistry, Longmans Green, V. VII, 1927, p. 714; Treadwell, translated by Hall, Eight English Edition, corrected, John Wiley and Sons, p. 218), although the exact nature of the complex is not established.

"Iron does not form a complex ferrous ion in HCl solution. When Pb and steel electrodes are immersed in HCl solution, and coupled, the lead electrode, due to the complex discussed above, is electronegative to the steel electrode, as shown in the table of voltages above and as indicated by the corrosion results cited above.

"F. T. Gardner.

"Subscribed and sworn to before me this 27 day of August, 1938.

"C. L. Thompson,
Notary Public."

Mr. Lyon: Now, I don't see anything in Dr. Gardner's affidavit here that has any of the iniquities about it. As you see, this current extends down an oil well pipe; he hasn't said anything about that. He has just established

the voltage and the direction of the flow of current in the electromotive series, and I don't think the witness has seriously disagreed with him on that.

The Court: He disagrees as to these results obtained here, as I understand. A. You have gotten out of me some preliminary work that we did in which I told the court that I disagreed—that I agreed quite closely and in general in the voltages. And then we ran a few inhibitions, and we got practically zero inhibition instead of 90 per cent.

The Court: That is where he disagreed.

Mr. Lyon: I see. A. They are preliminary results. But they indicate that with certain types of metal you get a slight inhibition.

The Court: You might have to disprove it; it isn't very severe, because there are so many chemists and you have so many you can readily run any, if you want to show me that that is the results you have obtained.

Mr. Lyon: Very well.

The Court: I think you intend to do that.

Mr. Lyon: That is right. But I want to point out Dr. Gardner, in talking about inhibition, percentage of inhibition, I don't think he was talking about oil well pipe. A. No, I don't think so.

Mr. Lyon: I think he was talking about the tank. A. Yes.

Mr. Lyon: He disagrees with him about the tank. A. I say we don't. I say we ran a few preliminary tests and the tests showed some inhibition when we used a piece of steel and covered the strip of it in the beaker with the lead sheet, we got 30 or 40 per cent inhibition. And when we used a sheet of strap steel we got no inhibition.

Q. But your tests have not gone far enough so as to disagree as to these values reported by Dr. Gardner as they apply to the tank rather than to the tube? A. I would say that from 95%, that is a tremendously high figure. I just can't see how when I got zero on several tests, 30%, approximately on another test, all of a sudden it is going to jump up to 95%.

Mr. Lyon: We have witnesses, Your Honor.

The Court: There is something funny in there as to why one gets zero, the other 93.

Mr. Lyon: That is pretty nearly as far as you can go. Only seven more. A. These are simply preliminary tests. I seriously question—

The Court (interrupting): How can you get zero if there is quite a lot there? A. Those are the results we got on this test.

Mr. Wiles: These tank tests showed a considerable pick-up in the iron in the tank which showed there was a lot of inhibition left to be done. Every time they put acid in the Menaul tank they picked up a lot of iron in it, showing the tank was being eaten away.

The Court: What kind of a test did you make when you practically got no inhibition? A. We took a sheet of strap iron, cleaned it up, as I recall, by sand-blasting or emery cloth.

The Court: As I understand, you followed as near as you could the teachings of that affidavit? A. Very similar, even closer together than that affidavit showed.

Mr. Lyon: I haven't found the results of those tests you last referred to in Exhibit 190. Maybe they have been made since this book was written up. Are they in this book 190?

Mr. Lightfoot: I believe they are. A. See page 9 for data, it says here (witness reading from book).

Q. That is part of Dr. Bartell's report that you originally started with. A. Oh, yes. 245 and 249.

Q. That seems to be (looking at book) that very queer apparatus that you said wouldn't work. Is that what you are basing that on? A. We ran a piece of lead in here (indicating) connected directly across with this piece of tubing, and we determined the inhibition. We put one strip of lead in here (indicating) and this section of oil well tubing with an extended arm on it and connected across between the two and found that when we connected it we got a reduction in attack of this piece of tubing of about 30%. I have the figures right here. Then we ran a test using

strap iron and putting the strap iron about an eighth of an inch away from the lead strip and inserted it in a beaker with a screw connecting up outside of the solution, and we got practically zero.

Q. What conclusion can you draw from that? A. I can't tell you. It was a preliminary test. When you asked me about whether the lead would protect the tank, I said it probably would to a limited degree.

The Court: Well, how do you explain in one you got about 30% inhibition and the other practically zero? A. Two different kinds of metals.

The Court: Is that the explanation? A. Possibly. The shape of the metal is different in the oil well tubing where we got inhibition. In other words, it was round. We had a strip outside here (indicating). It differed somewhat from Gardner's test. We got inhibition there.

The Court: When you got 30% were you nearer to Gardner than the other? A. Gardner reports 90 plus per cent.

The Court: I don't mean that. In the performance of the test. A. The one we got zero we were closer to Gardner in the method of performing his test.

Mr. Owen: In the one you got zero did you follow Gardner? A. Very similar. Two strips of lead, and we put them closer together than Gardner shows.

Mr. Owen: And did you connect them? A. Connected them together.

The Court: Don't tell me the differences now but tell me to what you yourself now attribute the different results in your two experiments where in one you got 30% and the other something else. If there are differences, you know; don't tell me the difference. Just tell me to what you attribute that difference. I want to get your idea. A. I imagine there is difference between potentials between the lead and different kind of iron.

The Court: You think it resulted from the different kind of lead you used and different kind of iron? A. Yes, and a matter of the difference in potential.

The Court: Have you told on the record what that difference was? Does the record now show? A. I don't recall. You mean in these little tests?

The Court: You attribute your difference in one case you got practically zero, the other case you got practically 30% inhibition, and you attribute that difference to the difference in the kind of iron and the difference in the kind of lead used in the two experiments? A. I believe that was the reason.

The Court: Tell me, then, what kind of lead and what kind of iron you used in the experiment where you got no appreciable inhibition. A. That was a sample of strap iron.

The Court: And what kind of lead? A. And the lead was chemical lead, I believe.

The Court: Chemically pure lead? A. No, a chemical grade of lead, just the kind they use in the bottom of these Menaul tanks. It was not chemically pure. It was the chemical grade of lead which they use in the Menaul tanks in the field.

The Court: All right. Now, tell me what kind of iron and what kind of lead you used in the experiment where you got practically 30 per cent inhibition? A. That was this oil well tubing cut out of lengths of this 1¼ inch tubing, and the lead was the same exactly. I think it was the same strip, wasn't it?

Mr. Lightfoot. No. A. It was off the same piece.

Mr. Lightfoot: A lighter grade of lead. A. Was it the same kind of lead?

Mr. Lightfoot: Yes.

The Court: You don't attribute it to the difference in lead? A. No, not to the lead, to the iron.

The Court: You attribute it entirely to the iron? A. Yes.

The Court: In other words, one was easier biting for the HCl than the other? A. That probably was it.

The Court: Well, all right. A. I hate to make real definite statements on three laboratory tests.

The Court: Your best explanation you can give me as to why— A. (Interrupting): I don't like to go on record as making any hard and fast numbers.

The Court: I understand that.

Mr. Lyon: Now, also there was furnished to us in response to our request for additional reports, if any, correspondence, six binders which don't seem to add very much in so far as some of them are concerned, to Exhibits 184 and 185, because they seem to be preliminary copies of those, but there are some additional statements I would like to call Your Honor's attention to. This binder I have here, which is entitled "Progress report on Menaul test, submitted by C. F. Prutton, March 1, 1940," is a copy of a report that you submitted to the Dow Company on that subject on that date? A. Yes.

Q. And it covers largely the same material which is now incorporated in PX-185? A. That is correct.

Mr. Lyon: I call your attention to the last page, which is entitled "General comments." "No. 1. The rate of attack of hydrochloric acid on various lengths of tubing seems to vary considerably from length to length and be quite dependent upon the method of cleaning the metal surface." Was that a correct statement of what you had found up to the date of this preliminary report in your test? A. I believe it was.

Q. And is it still a correct statement of your observations? A. I think so, yes.

Q. "No. 2. In duplicating the Menaul procedure the amount of inhibition exhibited was much greater than would be indicated by the chemical inhibition shown by the entering acid."

Was that likewise a correct statement of what you had found at the date of this preliminary report? A. I don't recall. I don't think so.

Q. You don't think that statement is correct? A. I don't recall. This report was written—may I ask Mr. Lightfoot? This was written before we ran these analyses for the improved new method?

Mr. Lightfoot: They were.

A. This report, on this preliminary report we ran the iron determinations by this inaccurate method with lead in them, and the conclusions would be based on that, and if that is the conclusion, why it was corrected when we received the analyses on the acid samples, and those analyses were repeated at last Christmas time, very close to Christmas.

Q. After and subsequent to your submitting this report, preliminary report of October, 1940, to the Dow Company,—I believe you submitted it to Mr. Rebbeck, did you not? A. I think they went to Mr. Rebbeck.

Q. Did you receive any communication from Mr. Rebbeck or have any discussion with him about the contents of this preliminary report? A. I don't recall definitely the conversations. I believe I talked to him about every report we sent to him.

Q. Now, as a result of some conversation or some communication, you were asked to do something to produce a different result from the one that I have just indicated, were you not? A. No, sir; that was not the case. The case is that we kept on working on the problem and we discovered these errors and we corrected them.

Q. This last comment, No. 2, that I read to you, which you state is not correct, in your opinion? A. I don't recall. I would have to look through this report.

Q. That is just contrary—wait until I finish my question, please—is just contrary to what you have reported in Exhibit 185, is it not? A. It is contrary, the statement.

Q. And you corrected that as a result of going out and getting some different method or new method after the date of this preliminary report? A. A correct method of analysis.

Q. Well, isn't it quite true that Mr. Rebbeck indicated that something like that would have to be done, because he couldn't use the results as you reported them in your preliminary report in this case? A. Absolutely not. Mr. Rebbeck didn't indicate that at all, and we continued

doing work to accumulate more data, and this report is on the results of a few of those very preliminary tests. I don't know how many tests there are in this report. Can you tell, Bill? You are the one that got the report together?

Mr. Lightfoot: They are all different sections of tubing, I believe.

A. I think these runs could be—this could be very well explained. It will take some study to do it, and I don't think the conclusion is valid at all. I would like to take this overnight.

Q. Sure. Doctor, if you have anything you want to correct in anything you have said on cross-examination, why I am sure I want you to have an opportunity to do it, and if you let me know why I will ask the court to allow you to be given that opportunity. Now, I did ask yesterday—

The Court: All witnesses in my court can do that. I am looking for the facts, and that is all.

Q. Plaintiff's counsel didn't let me have the correspondence between this witness and Mr. Rebbeck. A. I have that. Do you want it?

Q. In view of the fact it is referred to at several points in Exhibits PX-184 and 185, I would like an opportunity to review that correspondence to see what the views are that were exchanged between this witness and Mr. Rebbeck in regard to the work that was to be done, and what the results were. Is this the complete correspondence? A. That is the complete file of correspondence to everyone connected with these tests, I mean, not only to Mr. Rebbeck.

Mr. Lyon: I will examine this this evening, Your Honor.

Mr. Lyon: Now, have we, as a result of PX-184 and 185, and these notebooks, and these additional preliminary or tentative reports that you furnished me, before us for study all of the experiments, and all of the work that you have done for this case, at least up to the start of the trial? A. Up to the start of the trial, or just shortly before. We have some laboratory inhibition tests that were reported in

the presence of oil that are not in these books, and they were completed after the start of the trial, and the books were not available to put the data in.

Mr. Lyon: I think that that is as far as I can go with my cross-examination, and I may not have any more; but I would like to look over this file of correspondence tonight, Your Honor.

The Court: All right.

Mr. Lyon: I am returning to counsel the six partial reports, or preliminary reports, and one of the two volumes he gave me is an empty book, except for two or three pages.

I am going to ask that the court receive as Exhibit DX-190 the original record book which I examined the witness on, and there is nothing in it except practically this data on this case.

Q. Dr. Prutton, I don't believe you testified to any determinations made as to the percentage of corrosion reduction or the percentage of inhibition of the Halliburton storage tank acids. Did you make any such tests of the acids that you made to simulate them? That is the acid in the storage tank before it is acted upon in the transportation tank. A. I don't recall that we did. If we did that it was some isolated test that we made, and we did so many of them.

Q. Do you know a Mr. Harold Robinson of the Dow Company? A. Yes.

Q. What is his position in the Dow Company? A. He is a physical chemist, in the Physics Laboratory there.

Q. I show you in your file of correspondence a letter addressed to you, dated September 12, 1939, signed by Mr. Harold Robinson. Did you receive that letter from Mr. Robinson? A. Yes, I received that letter.

Q. And the letter contains this statement, does it not, "We would prefer to use the same commercial acid (General Chemical Company, Chicago) as was used by Halliburton in the well treatments with which we are concerned, if we could be sure that the acid would have inhibition of the same order (10 to 15 per cent) as the Halliburton stor-

age acid. We have observed occasional high inhibition in this and other commercial acids. I should say that there might be an advantage to using Graselli acid in that you would probably have a chance to check on the inhibition before buying it in any large quantity." I have correctly quoted the letter, have I not? A. I don't recall.

Q. Just read it over, if you will. A. You quoted correctly from the letter.

Q. Now, you understand from this letter that the Halliburton acid corresponding to that used by Halliburton in the well treatments which had been sampled was acid from the General Chemical Company of Chicago, and was inhibited and contained in its raw state inhibition as high as 10 to 15 per cent, did you not? A. Well, the story of the initiation of this work is not simply—cannot be taken from one letter. There were a series of conferences and discussions that were held between myself and Mr. Chamberlain, and also Mr. Rebbeck.

Q. I asked you if you had that understanding of this paragraph. If you will just answer that question, then we will get along to another. A. I didn't pay any attention to that paragraph.

Q. You didn't? A. No. I did not pay attention to a lot of things that Robinson told me to do. He was a sort of an assistant in the laboratory with Mr. Chamberlain, and instead of specifically following his instructions I took more of my general directions from these conferences with Mr. Chamberlain, who was his superior. Robinson suggested, for example, a tremendous amount of electropotential work that would have taken months and years and many men to do, and I simply didn't follow that.

The Court: Is Robinson still with the Dow Company? A. Yes, he is.

Q. Who suggested that you make your comparisons and your experiments with Graselli acid, which, as you have suggested, was practically chemically pure, rather than with raw commercial acid of the type used by Halliburton, which in its raw state was 10 to 15 per cent in-

hibited? A. Well, I can't enlighten you upon that. You found in our books and we evidently ran inhibition tests on this Penn Salt acid and Graselli acid and found some slight inhibition, and the purpose of the tests, as I saw it, and I was given quite a good deal of latitude, not at all times specific instructions from these men at Dow. I received letters from Robinson with many detailed suggestions, but I followed very few of them. I don't recall hardly any that I followed. The outline of the whole problem, the general problem was to determine if in a large scale set up these metallic components would greatly inhibit the acid and to determine the effect that this lead plate in the Menaul process had contributed to that inhibition, or whether it contributed at all. And the decision to use the acid, we must have discussed, for I ran this Penn or our men ran this Penn Salt acid. That must have been discussed in one of these meetings or conferences we had, and here with two types of commercial acid, and then with Graselli's very close to us, and in my opinion it made no difference, practically, as to the finding of this work, the general findings, as to whether a considerable amount of lead and some copper in the acid would greatly inhibit—increase the inhibition of commercial acid when run through a pipe system. That I think we have done and I think is independent of a variation in some small percentage in the acid inhibition.

Q. I show you a letter under the letterhead of The Dow Chemical Company, addressed to you, "Re: Acidizing Contact Time" signed by Mr. J. Rebbeck, Patent Department. Did you receive this letter? A. I did receive it.

Q. Is this Mr. Rebbeck's signature? A. It is.

Q. Mr. Rebbeck is the witness who was here on the stand sometime ago in this case. A. Yes.

Mr. Lyon: I want to read this letter to the court. It is dated January 24, 1941. In reading it to the court I will ask the court to have in mind the Dow men were present at these wells where they have obtained these samples, so they have full information as to the facts that are reported in this letter by the Dow Company.

Mr. Lyon: I think I will offer in evidence the previous letter dated September 12, 1939, from Mr. Robinson to Mr. Prutton. With the understanding if you don't want to destroy the file, the reporter can copy it in.

(Whereupon the document above referred to was marked DX 221, and reads as follows:

"THE DOW CHEMICAL COMPANY
Midland, Michigan, U. S. A.

September 12, 1939.

"Dr. C. F. Prutton,
Case School of Applied Science,
Cleveland, Ohio,
Dear Dr. Prutton:

"We have already forwarded to you under separate cover data relative to the composition of Halliburton lead and that section of the depositions dealing with the layout of the truck tanks.

"As for the ratio of Pb area to Fe area and the composition of the steel used for the truck tanks, I am asking Conner to get this data as soon as possible. We should be able to get the Pb-Fe area figure without much trouble, but as to the other item there may be some delay. I assume that in the case of the steel analysis you are mainly concerned with the copper content, insofar as it will determine whether or not your tank produces an acid having approximately the same copper content as the Halliburton truck acids. (We have some experimental runs which show that the copper in the acid is derived from both the lead and the iron, for a well tubing—Halliburton Pb couple in 15% HCl.) In order to avoid having to duplicate the steel from Halliburton's tanks, we might substitute for Test Run C a run similar to B, except that the acid in the crock would be synthetic Halliburton truck acid, i. e., metals added, which would be run through the steel tank rapidly as in B in order to avoid further metal pickup. That is, the inventory in the steel tank would be kept just high enough to allow for siphoning and getting the electrical output of the

couple into the tubing, possibly a 20-gallon inventory or thereabouts. I take this to be what you have in mind for Test Run B. With this procedure, we need only be concerned with avoiding an excessively high copper steel. So far as I know the electrical output of the cell is not going to be appreciably effected by the usual variations in steel composition.

"The tubing you require can be purchased from the Oil Well Supply Company, which has supply houses at Pittsburgh, Oil City, Franklin, and Butler in Pennsylvania and at Wooster and Newark in Ohio. This tubing is made by the National Tube Company.

"Bartell has been using 2" API seamless tubing. The smallest tubing of this kind available appears to be 1¼" nominal (1.38 I. D.), but to get this under A. P. I. specifications it is necessary to take an external upset joint, which you will probably only cut off anyway to get steel samples. The specifications for this tubing are as follows:

"National A. P. I. External Upset tubing (quantity required), 1¼" (nominal), 2.34#/ft. with threads and upset without coupling, seamless, external upset, grade C. Specify length wanted.

"The same tubing without the upset and lacking A. P. I. recognition or approval is sold at National Oil Well Tubing, 1¼", 2.27#/ft., seamless, plain end, grade C. According to the catalog data, this tubing is the equal of the A. P. I. tubing as regards thickness, test pressure, tensile strength, bursting pressure, etc., and has the advantage of having plain ends from which samples may be cut off without sacrificing a special construction.

"Dr. Bartell has not indicated what grade (B, C or D) of tubing he is using. Usually when this is not specified, the distributor supplies grade C and I assume this to be the case here. I will confirm this as soon as I can reach him.

"Tubing is supplied in two ranges of length: range 1 averages 21 feet with a minimum of 20 feet and a maximum of 24 feet. Range 2 averages 28.5 feet, maximum of 32 feet,

minimum of 24 feet. Tubing will also be cut to length when so ordered.

"We would prefer to use the same commercial acid (General Chemical Company, Chicago) as was used by Halliburton in the well treatments with which we are concerned if we could be sure that the acid would have inhibition of the same order (10-15%) as the Halliburton storage acid. We have observed occasional high inhibition in this and other commercial acids. I should say that there might be an advantage to using Grasselli acid in that you would probably have a chance to check on the inhibition before buying it in any large quantity.

"We will arrange with Dr. Bartell to have him send you the corrosion strips for inhibition testing. It would be advisable, however, to cut off a small section (at least 4" long) from each pipe section that you use and to have the former cut up into corrosion strips which could then be checked against Bartell's material. In any event, it would be a worthwhile precaution.

"I am enclosing some notes and comments on the setup and tests which you propose to use. We hope they will facilitate the work and possibly help you to avoid some trouble.

"Very truly yours,
The Dow Cemical Company,
"Harold Robinson.

"cc:
C. A. Campbell.
L. C. Chamberlain."

The Court: The letter of September 12, 1939 as I understand it, is from Robinson to Dr. Prutton, is that correct?

Mr. Lyon: That is correct.

The Court: And the other one is January 24, 1941, DX-222.

(Whereupon Exhibit 222 was marked by the Reporter.)

Mr. Lyon: This letter of January 24, 1941, is addressed to Dr. C. F. Prutton, Case School of Applied Science, Cleveland, Ohio.

"THE DOW CHEMICAL COMPANY
Midland, Michigan, U. S. A.

January 24, 1941.

"Dr. C. F. Prutton,
"Case School of Applied Science,
Cleveland, Ohio.
Dear Mr. Prutton:

"Re: Acidizing Contact Time.

"Pursuant to a suggestion made by Mr. Owen recently to examine the data in the Halliburton reports on well treatments performed by them and observed by us, I have ascertained from their tickets the approximate time during which the acid introduced into the well was in contact with the well tubing and the rate of flow of the acid through the tubing. The following is a tabulation of the pertinent data, which is taken directly from the Halliburton acidizing tickets for three wells. I have added a column of figures entitled "Gallons per Minute," which is the average rate of flow computed from the time and volume of acid introduced.

"Stella Wilcox No. 3

Time	Vol. Acid In	Pressure Gasing	Pressure Tubing	Gal. per Minute
9:30 A.M.	Start	0	0	
9:35 A.M.	500 gal.	50	15	100
9:40 A.M.	1000 gal.	100	15	100
9:42 A.M.	1200 gal.	100	100	100
9:55 A.M.	2000 gal.	100	400	65
10:30 A.M.	15 bbls. oil	50	700	
11:00 A.M.	25 bbls. oil	0	600	

Zahn No. 2 (First Treatment)			
11:00 A.M. Start	0	0	
11:03 A.M. 250 gal.	75	20	83

"From the foregoing information it appears that the contact time could be computed as being the difference between the starting time and that at which the whole charge of acid was in the well, and this assumes, of course, that it takes about as long to fill the tubing with acid as it takes to empty the tube after the charge of acid has been put in, an assumption which may not be justifiable in all instances. On the basis of this assumption the contact times would be as follows:—

"Stella Wilcox No. 3—25 Minutes.

"Zahn No. 2 (First Treatment)—3 Minutes.

"Zahn No. 2 (Second Treatment)—5 Minutes.

"Crawford No. 5—145 Minutes.

"The lengths of the tubing in each of these wells were 2600 feet for the Stella Wilcox No. 3 Well, 2600 feet for the Zahn No. 2 well, and 2676 feet for the Crawford No. 5 Well. This was 2 inches 4.6 pounds Spang API lapweld Range 1 pipe, the I. D. of which is 1.995 inches.

"We are concerned as to whether or not the observed inhibition values in your experiments (which are computed on the basis of the relative amount of iron picked up by raw acid solution compared to that of Menaul acid solution in passing through the experimental pipe) would show substantial or similar values of inhibition if the time of contact and rate of flow and pressure were made to cor-

respond exactly with those involved in the foregoing well treatments. It may be desirable to perform some additional experiments wherein the flow rate and time of contact, and possibly even the pressure, exactly parallels one or more of the Halliburton treatments for which we have data. If under these conditions a substantial inhibition is found, the experiment would tend to prove the acid is inhibited in actual practice of the Menaul process in wells. Please let us have your views as to this.

"Very truly yours,

J. W. Rebbeck,
Patent Department."

Mr. Lyon: At the adjournment last night I had just read Mr. Rebbeck's letter outlining the times of the contact of the acid in the pipe, in the three wells that the samples were taken from; it has been referred to in the evidence here as his suggestion that you run experiments to see what you would find the relative inhibitions to be under those conditions. Now, the only experiment that you referred to, I believe, in your testimony, or that is covered in your reports, where you attempted to run the acid at a different rate than one gallon per minute, was an experiment in which during half the time you ran it faster, but I believe you had no measurement of just how fast, and you did not make any determinations. That is correct, is it not, Dr. Prutton? A. That is correct, but there was oil present.

Q. Now, I find in this book of correspondence a carbon copy of a letter dated February 19, 1941, addressed to Mr. Rebbeck, and signed in typewriting "C. F. Prutton." Is this a carbon copy of a letter which you sent to Mr. Rebbeck in reply to the letter that I read last night (showing the document to the witness)? A. Yes, that is a reply, and is—

Q. (Interposing): I will read it, and then we will discuss it. I will ask to have this carbon copy of the letter marked DX-223.

(The letter above referred to was thereupon marked DX-223.)

Mr. Lyon: DX-223 reads:

February 19, 1931.

"Mr. J. W. Rebbeck,
"The Dow Chemical Company,
"Midland, Michigan.
"Dear Mr. Rebbeck:

"Attached are three copies of report on all data accumulated by us on laboratory inhibition tests. Several questions raised in recent letter from you, may be answered by this data.

"1. What is the inhibition of Halliburton's storage tank acid diluted to 4.3% N concentration?

"Page 7, Sample 2, is diluted C. P. HCl in distilled water, yielding 78.9 grams iron per meter per hour rate of attack. Sample 3 is 4.36 N Halliburton storage tank composition showing 52.5 grams iron per meter per hour. Per cent inhibition is therefore $78.9 \text{ minus } \frac{52.5}{78.9} \text{ times } 100$, which equals 33. per cent."

I call Your Honor's attention that there is a determination by the witness that the Halliburton storage acid, on the basis of making these determinations, has a 33 per cent reduction in corrosion.

A. (Interposing): May I discuss that?

Q. (By Mr. Lyon): I will come back to this letter in a few minutes. A. All right.

Mr. Lyon (continuing reading):

"2. What inhibition would Menaul acid show if the acid treatment required as low as three minutes only.

"Page 8 and first paragraph $107.0 \text{ minus } \frac{88.}{107.} \text{ times } 100$ equals 17.8 inhibition in three minute test, since Menaul acid showed $72.5 \text{ minus } \frac{22.5}{72.5} \text{ times } 100$ equals 69.0 per cent inhibition in a three hour test.

"However, a three minute acid treatment would require high turbulence in the acid contacting in the tubing, thus differing widely from the static conditions in these laboratory tests.

"3. Comparison of analysis of Menaul tank acid with time of standing in special tank."

And I am not interested in the reading of that third subject at this time.

The Court: When he says Menaul and Halliburton, he is talking about the same thing?

Mr. Lyon: When he was talking about the Halliburton acid in the first place, he was talking about the tank acid, I mean the storage acid, storage tank acid, and when he talked about the Menaul tank acid he was talking about the transportation tank.

The Court (interposing): What I have is difficulty in just grasping the theory.

(The Witness): May I explain it? Did you want me to?

Q. (By Mr. Lyon): I will ask you, to give you an opportunity.

Q. In the first place, Doctor, you did not report this data in Exhibits 184 and 185? A. No, because we felt it not representative.

Q. And you haven't revealed it in your testimony? A. I have revealed in general, not the specific tests. No, I haven't revealed anything about the velocities.

The Court: I am trying to get the theory of that letter and I will ask the witness if this isn't true—those figures that they give, those three inhibition results, wouldn't that mean two things: First, we will say it would mean that by the Menaul test it did increase inhibition and the longer it stayed up to a certain point, the higher inhibition. Wouldn't it show that? A. One thing I want to be sure you understand and get straight. The time he gives there is the time of contact of the acid with the tubing, not in the Menaul tank, but the contact of acid with the tubing. I want that thoroughly understood first.

The Court: All right. Now, that answers one thing. Now the other conclusion I drew from it is that you naturally would draw the conclusion from that that it was added to the storage tank acid because it couldn't be lower than it was before it left. Is there anything you can put in to increase inhibition? A. It has inhibitors added by contact with the Menaul tank. This is the storage tank at the station now.

The Court: And that shows a higher inhibition, that three minute test? A. I think you have got to compare the same time of contact with the same time of contact. I would like to explain that contact.

The Court: In other words, there are two different kinds of analyses, the first one the Halliburton tank acid is an analysis, that of qualitative of the same kind of analysis by taking that and testing it and by putting some iron in it and see how much, in that way? A. That is correct, except that I did not analyze the acid. We made up a synthetic acid to duplicate some figures that Mr. Rebbeck had given me and stated that that was Halliburton storage tank acid composition. He thought that and he said run it in your laboratories and test.

The Court: Is this your letter? A. That is my letter.

The Court: Where did you get the 33 per cent? A. We determined that.

The Court: In what way? A. By taking this letter of Mr. Rebbeck in which he said it is .93 per cent or parts per million of copper and Halliburton's storage tank acid they figured so many parts per million of lead, which I don't recall, and of iron, and with the chemically pure acid, and added to it the amounts of those metals to make up a synthetic mixture, which agreed with this analysis that Mr. Rebbeck stated to me was this storage tank acid.

The Court: Did you get that by putting some iron down in there? A. And then we took that acid which we made and put one of these collars of 1¼ inch pipe into it for three hours in our standard laboratory test procedure and determined how much iron it ate off, and it showed 33 per cent inhibition.

The Court: Well, between you, if your figures were right, you determined that Halliburton storage acid, if you didn't make any mistake, and everything just as you did, if they had that whole tank to use, and could and did put some iron in it? A. If the analysis was correct.

The Court: All right. That was the way I got the idea as to how that came. Now, how did you get—you got the next by letting it run past the iron for three minutes? A. No, we immersed this collar of tubing into the acid for three minutes and then withdrew it and determined its loss of weight in this inhibition test. We took acid which corresponded to the Menaul tank acid. That is the acid such as was found leaving the Halliburton tanks as it went into the well, with a collar of about three to four parts per million of copper, and three or four hundred of lead, three or four hundred of iron. We made up a synthetic Halliburton acid.

The Court: The way I understand inhibitions, and your finding about a quality of the solution, isn't that it? A. It is not always a solution.

The Court: You are using inhibition in an unusual way if you are talking about how much it is inhibited for that use at a certain length of time? A. It is inhibited, but it is tied in with the metal, and a number of other factors in the determination.

The Court: Do you mean the same acid there you found on one acid 17.8 and another 16.903? A. Yes, sir.

The Court: The same acid? A. Except that the time—

The Court: They were poor tests? A. No, no.

The Court: What acid is inhibited to a certain extent when the other is put in? A. That is it. It isn't per cent inhibition, or I should say per cent inhibition is not a constant.

The Court: You are talking about how much inhibitor we can have in acid? A. That is true, but the time of contact and the factors of the nature of the metal surface—

The Court: I take a piece of some acid and I put it down into a well, it don't determine how much it eats it, it determines the quality of that acid, when I start to put it down into the well, doesn't it? A. That is correct.

The Court: That is what I am trying to get at. A. There is no way we have of getting a number which is independent of other variables that expresses that inhibition.

The Court: Given a certain piece of acid, is it possible that science cannot tell me whether it is inhibited—not only whether it is inhibited, but the percentage of inhibition? A. It is not possible to tell you exactly the percentage of inhibition.

The Court: I want to get at my fundamentals here. I supposed— A. (interrupting): The percentage varies.

The Court: I had supposed after all of the testimony I have heard, that here is a gallon, or a barrel, or a million barrels of acid, all in one container. Now, understand, I am not talking about how difficult it is to do the trick, but I had supposed that that acid was either inhibited acid, or it was not inhibited acid, independent of any use, except as to iron—why, it is hydrochloric acid, and it is either inhibited as to iron, or it is not inhibited. Am I correct? A. That is right, that is correct.

The Court: Now, I am not talking about how difficult it is, but I had supposed that there was some way to tell the percentage of inhibition of that acid over there, independent of its use. It is hydrochloric acid, and it is inhibited as to iron, I supposed—we have agreed now that it is inhibited, or it is not inhibited; and then I come over to percentages, and I have supposed that as to iron it was inhibited, say, 30 per cent, or 70 per cent, or 15 per cent, or some certain per cent, no matter how difficult it is to obtain it, or what method you used, I had supposed that that was a characteristic of that acid, that is, that it would be correct to say—without saying how fast somebody is going to move it, or where they are going to put it—that I could say that it is inhibited, say, 37.5 per cent? A. You cannot do that.

The Court: Then I have got a wrong conception of inhibited acid. This is now in the fourth week of this trial. Somebody will have to tell me what—somebody will have to explain, when you say an acid has a certain percentage of

inhibition, what it means. A. I think your concept would be all right if you would follow it just a little further.

The Court: I understand that it will eat more or less, depending on how fast it moves. But another man will test it and get a different result then?

Mr. Wiles: His may or may not be parallel. He may have different figures.

The Witness: That is not correct. If you have a condition constant, then you are going to get the same thing.

The Court: Certainly, but, you take the same tank, one man will drive farther than another with it, and another man will take the tank of acid, fill it up, and drive a mile with it and dump it out. But another fellow fills the same kind of acid into his tank, and lets it stand all night and drives twenty miles and dumps it out. One acid is inhibited more than the other acid is.

I have had a different conception of it. I have had the idea that one acid—as I say, they are both iron tanks, which is the same kind of acid, only one tank goes farther. I have understood all the while this difference in results. I have understood that if you take an iron tank and put, we will say, chemically pure raw acid in it, and drive for just an hour and dump it out, you would not eat your tank so much as you would if you put that same acid in a tank, and let it sit all night and then drive a hundred miles with it and dump it out. I understand that the second acid would eat more than the other, although they were just alike. But, I have supposed that you could say that those two acids were inhibited to a certain per cent, and they were just alike, one was just the same as the other.

Now, I have talked about pure acid, but I will take one that is inhibited, I will say up to 20 per cent—they are inhibited to 20 per cent, and I put the same acid out of the same vat into two different iron tanks, transportation tanks. One of them I let sit there all night, and I haul it the next day, and at noon dump it out. The other one I haul promptly and dump it out.

Now, I have supposed that those two acids were in-

hibited to 20 per cent. I supposed that that could be determined. I have supposed that the one, because it was a longer time in contact with the iron tank, would eat more than the other. But, now, I find that I must not say that those two acids were alike, and each inhibited to 20 per cent. I must say that one of them was inhibited a short time to a lower per cent than the other one. Now, that is a fine definition that we have got, that is all I have got to say, talking about acid. If you eliminate the use of it as applied to acid at all, and apply it to results, and say acid containing this, in that length eats so much, or is inhibited from eating so much, I can understand it. But you have been using this as applying to the acid, the quality of the acid. Now, you cannot convince me that the quality of those two acids was not just the same. I have taken them out of the same tank, put them into two different iron tanks, and their inhibition was the same.

Mr. Wiles: Certainly.

The Court: And characteristic and strength and vitality, and if you want to apply this term to them you ought to work out some way of using that so that it wouldn't be so confusing as it is to say that one is inhibited to a great— you say one is inhibited to greater strength than the other, although I dip them out of the same tank? A. No. When you say per cent inhibition, I mean the time of contact which I ran the sample, the metal that I used, the temperature.

The Court: You are talking about results then, aren't you, and not about your acid? A. Absolutely.

The Court: Then apply inhibition to results and not to your acid, if it doesn't apply to the acid, am I not right about that? A. No.

Mr. Wiles: That is like every other thing.

Mr. Lyon: I should think the witness ought to answer first, because I don't know what the testimony of the witness is going to be.

Mr. Wiles: We have these material tests made by the A. S. T. M. and every one of them you adopt a standard test. We have an anti-knock test. You have got that test

in a standard engine, or it don't mean a thing. There is 78 octane gasoline and 72 and it means a definite thing, but it is only 78 if we try it in the standard engines at these times and temperatures.

The Court: Per cent of inhibition doesn't apply to the acid, does it?

Mr. Wiles: Just as much.

The Witness: Not solely to the acid, not entirely, but it applies to a considerable degree to the acid under definite conditions.

The Court: You are talking about a result, aren't you, when you say degree? A. Well, the result is what you measure.

The Court: You have got two acids that are just alike, you dip them out of the same thing, and you use them differently to get different results, don't you? A. Yes.

The Court: If there is a different percentage of inhibition in your acids— I dip them out of the same tank,—I use them different and of course I see that, don't think I am so dumb I don't see it get different results, but is there a difference in the acid in percentage of inhibition? A. Not fundamentally when you get back to the acid alone, unless you have these stipulated things. It is just a common practice, a method of measuring the reduction of corrosiveness of acid to specify under what conditions you run that test.

As Mr. Wiles explained, we say gasoline is 78 octane rated, and I think if you want to define that you would say that is an exact number, and that depends on the gasoline, and you could say, yes, it does depend on the gasoline, but when you describe that number you have to tell the dimensions of the engine, the temperature of the air, the exact, specific method of measuring that, and give about 101 different details, instead of five or six.

The Court: Well, if I want to measure something I recognize that you can standardize it and say that whenever we use that we refer to these specific conditions, and if you would only say or understand that we will say gasoline is of a certain test, or you can say what the temperature is,

so and so, and pressure is a certain thing, and other conditions, I recognize go in to make that which is standardized, and you can do that. If you don't, then I don't see how you can apply percentages to a particular mixture I have. You must go over to your results obtained, in my judgment. A. That is exactly what has been done here, I believe. We have reported per cent reduction in corrosiveness under specific conditions of test, and the question is whether the conditions of test have been in any way valid.

The Court: Now, I am not talking about results to defendant, because I think I understood all along your theory about that. We are just talking about what people mean when they say things. That is all the way this becomes important here on this record. You will find a lot of things have been said already about percentage of corrosiveness and comparing it with some other, to percentage of corrosiveness.

Now, does the defendant agree with the plaintiff that this term as applied can't be used at all unless you state what the conditions—that you can't tell the percentage of corrosiveness of a particular mixture that you have, and you can't be certain as to so many percentage of corrosiveness, or inhibition?

Mr. Lyon: We agree with that, with this meaning, that unless you specify all the conditions which would materially affect the value of the percentage, all those conditions which existed in the test, then your figure has no meaning at all.

The Court: Then you never could speak of an acid that is in a tank as being a certain percentage of corrosiveness, or a certain percentage inhibited.

Mr. Lyon: In other words, Your Honor, just to make it very simple, and take one factor, these results which they have charted here with these comparative charts only show these differences in percentage which would exist on a three hour test. They wouldn't—this chart wouldn't be the same if for some substantially different time, would it, Doctor?

The Court: I recognize that.

The Witness: I don't think it would, no. We haven't claimed it would.

Mr. Lyon: In other words, we don't care whether the acid is in there for three hours or for three minutes.

The Court: We never should say an acid is a certain per cent inhibited and stop there.

Mr. Lyon: That is right.

Mr. Owen: In order to show that this acid is inhibited we have conducted two kinds of tests. Dr. Bartell first conducted tests in which he took defendant's actual acids from their storage tanks and from their truck tanks, and he compared them, he tested them under similar conditions as to time, temperature, size of test piece and amount of acid, and he found that under those conditions the truck acids were inhibited much more than the storage acids.

The Court: Depending on how much they ate; that was all, wasn't it?

Mr. Owen: And another thing he did, in order to see what the effect of these small amounts of copper and lead and iron had, he made synthetic acids in which he started with C. P. acid and added these metals to that, and then he compared the corrosiveness of the C. P. acid with that of the synthetic acids under similar conditions.

Then Dr. Prutton took up the work, and Dr. Prutton also conducted two kinds of tests. First he conducted laboratory tests in which he followed generally the methods followed by Dr. Bartell, in which he made synthetic acids by adding to chemically pure acid these different kinds of metals.

The Court: Yes.

Mr. Owen: And he tested the C. P. acid and the synthetic acid, side by side, under similar conditions. Then, in order to come closer to actual field conditions he built up this apparatus which he has described, and he tested the Halliburton acids against commercial acid purchased from Grasselli Chemical Company, and he took a different standard. He did not take the C. P. acid. He took the commercial acid. And then he did two things. He built up

that commercial acid synthetically by adding metals in amounts comparable to those found in the defendant's acids, and he tested those through this apparatus, running it from a stoneware crock where there could be no change except that which took place in the pipe, and then he went further and he built a tank to simulate the Halliburton tank, and he put commercial acid into that tank and let it stand there for six and a half hours, and stirred it every fifteen minutes, so as to get as nearly as possible an acid that would have resulted had the commercial acid been carried in a Halliburton tank for six hours.

Then he ran that acid from this simulated Halliburton tank through the system, and he analyzed it to see how much copper or how much iron there was when it started through the piping system, and he analyzed it to see how much there was when it got through, and he took the amount of iron that was taken up from the pipe and compared that amount with the amount of iron that was taken up from the pipe with the commercial acid, without any additions, run from the crock through the pipe.

The Court: You take a given acid, and you run it for three minutes, you get a different inhibition than you do if you take the same acid and run it for three hours, don't you? A. That is correct. I have a chart of the inhibition against time, Your Honor.

The Court: All right. I follow that. Now, we will say you get 17.8 if you run it three minutes, and we will say that you get 69.03 if you run it for three hours? A. Yes.

The Court: Is it correct to say that acid is acid of a certain per cent inhibition, and say nothing more? A. No. We have got to describe the tests, and we have tried to do that.

The Court: If you put it in an iron tank and haul it for three minutes, you get a different result than you do if you put it in an iron tank and haul it for three hours? A. You get a different result.

The Court: Would it be correct to say that the acid

you put in a tank had the same inhibition, and stop there? A. The acid is the same.

The Court: I know. Now, don't misunderstand me, I am just talking about how to talk about this thing, and how we have been talking about it, and get it on the record. I understand exactly now that it is going to eat more, the longer it is in there. I understand there are other things entering into it. I want to know whether it is correct to say that the acid had the same percentage of inhibition, if you put one in a tank and haul it for three minutes, and you put the acid in another tank and haul it for three hours. Is it correct to say—is it correct to use that term, that it has got the same inhibition? A. No, I would not use it. I would describe how long it was in the tank.

The Court: Well, in this record you will find that that is done. I am trying to get it clearly on the record, but you can't use that expression with reference to acid. It is only when you state all of the elements, according to your testimony, is that right? A. That is correct.

The Court: It depends, too—you take the same acids, and you take different kinds of iron—you go to two different places and get iron, and you put one into one vat of this same acid, and you put the other into another vat of the same acid, you get different results—your iron is different? A. Somewhat different, yes.

The Court: Then it is not correct to say that you take acids of the same percentage of inhibition, is it? A. No, not without explaining the tests and the results.

The Court: They have got different inhibitions, because you have used them differently? A. The popular conception of the term "inhibition" is—

The Court: Oh, I know, but I want to know just how wrong we have been in using the definitions here. We should not apply it to the acid when we get to percentages. You can say it is inhibited, that it is capable of inhibition? A. Yes.

The Court: But when you get down to percentages, you must not say it any more, is that right—we must stop

using it? A. With reference to a certain figure. You have got to define conditions, and the popular use of the term "inhibition" is an erroneous one.

The Court: Well, I take my acid, and I haul it in a wooden tank, nothing else touching it, only the wood—what is its inhibition? A. If I am to answer it, the way I would report inhibition—

The Court: Now just wait a minute. I did not take it out, I didn't do anything with it. A. I would say that you would have to take the acid out of that tank.

The Court: But I didn't take it out. You can't take it out of that tank. I have put it in there, and I keep it in there twelve hours, and I haul it all around. Now, I want to know whether it is inhibited, or not. A. And you take some out and test.

The Court: You have got to take it out and put it in with iron? A. Absolutely.

The Court: Then you can't tell how much, except that you state how long and whether it was agitated. They are just as necessary as those who describe the acid. A. Not quite.

The Court: How can you state percentages, one without the other elements? A. You can't.

The Court: If you keep it in the wood and don't let it touch anything else, what is its inhibition? A. You have got to run a test.

Mr. Lyon: The percentage of inhibition you get by that test will be different if you have two different kinds of iron that you tested on? A. It will be somewhat different.

The Court: All I am bringing out is now that the way we have been using the percentages don't apply to acid and the stuff that is in it. The percentages apply to the acid, that stuff that is in it, the time that is used, the agitation, and all the elements that figure into it, and it is only as to those results, in other words, that it applies, and that result and that percentage in the result is contributed to, I understand that fully now, and you don't need to worry about that, it is contributed to by the acid and it is con-

tributed to by the time, but whenever you use the term percentages you are talking about results and not about the things that go in to make the result. A. That is involved in it, but it is not the sole factor.

The Court: But you mustn't apply the percentage over to time? A. No, sir.

The Court: You mustn't apply percentages over to agitation? A. No, sir.

The Court: You mustn't apply percentages over to the acid? A. Not alone.

The Court: Not in inhibition now. Of course, you couldn't apply it all the time? A. You have got to take them altogether.

The Court: But when you come over to talking about percentage of inhibition of corrosion I must not apply that to the acid at all, and I must not apply it to whatever is put in as an inhibitor. All right. Now, we have got that, I think, clear on the record. A. It is a method of comparing acids under similar conditions, and that is all. I would like to answer the questions raised in that letter.

The Court: You mustn't say an acid is a certain per cent inhibited because no chemist is wise enough to determine that. Doctor, given a quantity of acid, you can't analyze that. A. Not without specifying the conditions. We can analyze it chemically.

The Court: Yes. But you are dealing with a proposition and you have used the definition as such after you have analyzed that you can't say it is a certain per cent inhibited. A. Not unless you make tests.

The Court: And then you get results depending on the condition. A. And comparison of one solution with the other.

The Court: Then it isn't comparable. Most things you take an analysis, you tell how much it is with this percentage. A. We have these chemical analyses. We say there is 1% lead. We determine absolutely. That is fixed on the sample.

The Court: Yes, I get that. You tell me the in-

gredients in it but when you talk about per cent inhibition you are not talking about the ingredients. A. No, talking about the performance of it under a definite test condition.

The Court: Then why don't we agree you are talking about results and not ingredients. Don't you agree with that? A. The ingredients contribute.

Mr. Lyon: All right, doctor— A. (interposing): May I explain the letter? We got sidetracked on the discussion.

Q. I will finish my part in a few minutes, and I will give you an opportunity then to explain, or they can.

The Court: I want to give you a full opportunity, doctor. A. Yes.

Mr. Lyon: I am going on with this, and it is not going to interfere, at all, I am sure.

Mr. Lyon: Doctor, when you reported the results of your tests to the Dow Company, you simply reported, did you not, the actual values that you found in the first instance? A. Why, I believe so. I always report results as to what I find.

Q. I mean the result, the measure—

Mr. Owen (interposing): I suggest that the witness be shown the letter that you are referring to.

The Court: Yes; he is entitled to see it.

Mr. Lyon: Yes, if there is anything he wants to see. A. What are you asking about?

Q. I am asking a physical fact now. A. The physical fact is that I report to a client sometimes in letters and preliminary statements, I report preliminary reports, and then finally when I get through summing up all the work that has been done, I arrive at some definite conclusion as to the results of the work and I report that. It has been referred to in the correspondence here.

Q. What I am getting at is this, doctor, these tabulations, such as PX-189, of the kind that were brought here, you did not prepare those at all? A. No.

Q. They were prepared by the Dow Company? A. Yes, that is correct.

Q. You were asked to include them in your report? A. Not in my report.

Q. In Exhibits 184 and 185? A. Well, it is not bound in my report. They brought those charts in, and we checked the figures on them.

Q. Now, doctor, the various tables that were included in your report, those were also prepared by the Dow Company, were they not? A. Absolutely none of them. They were all prepared by us.

Q. You prepared these reports and submitted them to the Dow Company, but as they appear in Exhibits 184 and 185, they have been completely re-written from when you first presented them to the Dow Company, have you not? A. I presented interim reports, by just reporting whatever came at hand, to try to give them a picture, and letters were written as to little changes that might have been made, or little differences.

Q. You say they were only little things. Weren't you asked to leave out some things? A. There were a lot of small tests that were made, of various kinds, and in making the final report that was brought in here, and which I don't think we submitted as a display or an exhibit, but was taken in as an exhibit, that was written, specifically going at one particular object, not to include all of the little miscellaneous things that we arrived at on the side, or—

Q. (interposing): I am going to ask you if this is one of the letters that you received from Mr. Rebbeck with reference to the data or the report after you had submitted it. This is dated July 18, 1941, addressed to you, and signed by Mr. Rebbeck, on the stationery of the Dow Company (handing the document to the witness)? A. That is a letter that was sent to me, and we revised the report in line with this, and, as I recall, before that letter was written to me, I had had a brief conference with Mr. Rebbeck in Midland, in which he just went over this, there were a number of typographical errors, and we went over the form in which the final report was to be prepared.

Mr. Lyon: I will ask that this letter be marked DX-224.

(The letter above referred to was thereupon marked DX-224.)

Mr. Lyon: I will read this to Your Honor, it isn't long. I will read the first part of it.

"DOW CHEMICAL COMPANY, July 10, 1941.

"Dr. C. F. Prutton,

"Case School of Applied Science,

"Cleveland, Ohio.

"Dear Dr. Prutton:

"Subject: Changes in 'Memorandum reports on Halliburton-Dowell case' June 20, 1941.

"Mr. Owen has reviewed the subject report and would like the following changes made. Will you please retype the pages to be changed and furnish us with copies for our reports?

"The changes to be made are as follows:

"First, number all the pages beginning with the title, 'The Effect of Pressure on the Corrosion of Steel by 15 Per Cent Hydrochloric Acid containing Inhibitors,' but omitting the memorandum of report entitled 'The Effect of Crude Petroleum Oil on the Corrosion of Oil Well Tubing by 15 Per Cent Hydrochloric Acid.' With this section omitted, the title page 'Small Scale Tests That May Be Used To Demonstrate the Effect of the Menaul Process' will be numbered 5.

"Revise the table of contents by omitting the second item, namely, 'The Effect of Crude Petroleum Oil on the Corrosion of Oil Well Tubing by Fifteen Per Cent Hydrochloric Acid.'"

Then there follow several pages of changes. I guess I will have to put them all in, as the witness has attempted to deny the latest report in existence that this letter mentions.

Q. The first of these letters asking you to revise your report, and also stating—I think I will read the letter so you can identify it. This letter is dated July 9, 1941, from you to Mr. Rebbeck, is it not? A. From Rebbeck to me.

Q. You received that letter, did you? A. Yes.

Q. I will ask that this be marked DX-225.

(The letter above referred to was thereupon marked DX-225.)

Q. The next letter is—well, on the same subject there is another letter of the same date, is there not? A. Yes.

Q. You received that letter? A. Yes, I received that letter.

Mr. Lyon: I ask that this be marked DX-226.

(The letter above referred to was thereupon marked DX-226.)

Q. The next letter is the letter that I have already read, which is DX-224. I have already read that. The last letter is a letter dated July 11, 1941. Did you receive this letter from Mr. Rebbeck? Did you? A. Yes, sir, that is correct.

Mr. Lyon: This will be DX-227.

(The letter above referred to was thereupon marked DX-227.)

Q. With reference to these letters, or this last letter, DX-227, that is the letter in which Mr. Rebbeck suggested to you the use of average of averages, and the averaging of various tests for determining what 100 per cent corrosiveness is, and the various matters that are involved—he worked out this per cent of corrosiveness and asked you to adopt it. You didn't do that, isn't that correct? A. As I said, as I recall I met Mr. Rebbeck some time in June, and I think Mr. Owen was there, and Mr. Conner, and these changes were discussed, and this method of representing the results. These are not any faked-up results. It is just a different way of writing the results, changing from per cent inhibition over to this reduction in corrosiveness, a different way of expressing the results. I saw no valid reason as to why it could not be done, and they said, "We will calculate your results, and you check them, and we will have the figures made up for you." And that was the way it was done.

Mr. Lyon: I don't think that it is necessary to read each of these letters if they are here, Your Honor, except

I will indicate as to DX-225. It says: "Subject Correction to Report Entitled Large Scale Test of Menaul Method of Acidizing Oil Wells dated June 20, 1941. Mr. Owen has reviewed the subject report and proposes that you make the following corrections or changes and that you retype each page requiring such changes or corrections, furnishing us with the retyped pages for each of the copies of this report." And then there is tabulated as to what he wants done.

DX-226 starts out the same way—"Subject Changes to be made in the report entitled Corrosion of Oil Well Tubing by 15% hydrochloric acid June 20, 1941"—these changes are made after the date that appears in exhibits 184 and 185. The date of the report is June 20, 1941. "The following changes are proposed as a result of the review of the subject of this lawsuit"—

The Court: When did we start this lawsuit?

Mr. Lyon: July 21st. Then the letter contains 2½ pages of changes. I have read from DX-224. DX-227 is the last one, dated July 11, 1941, and reads: "Dr. Prutton, for the purpose of constructing charts, summarizing your findings as to the corrosiveness of commercial hydrochloric acid to which you added iron, lead and copper, I have made some calculations reducing this data to relative corrosiveness as follows"—and then includes preparation of these things. I mean his method of calculating these things. This is signed by Mr. Rebbeck to this witness. The letter concluded: "It will be desirable for you to be familiar with the origin of the figures appearing on the proposed charts, and for that reason I have given you the methods used in computing them. In addition, there is enclosed herewith a typewritten form which will represent substantially the layout of the completed charts. I believe you should check the computations to be sure that the figures are right. If you find any errors, please immediately advise. Mr. Rebbeck, Patent Department."

Now, the purpose of this is so Your Honor will understand and distinguish in this testimony between what was

this witness' experimental data and what is the form in which it is reported, and whose idea and whose responsibility the form of the reporting is.

I think that is all the cross-examination.

REDIRECT EXAMINATION

By Mr. Owen:

The Court: Now, Mr. Owen, don't forget to give the doctor the opportunity that I very earnestly promised him.

Mr. Owen: I will try to, Your Honor.

The Court: I want him to have every opportunity.

Mr. Owen: With the character of the cross-examination, Your Honor, it makes it necessary for me to review to a considerable extent what Dr. Prutton did in preparing his work in connection with this case.

The Court: I will leave that to you.

Mr. Owen: I am going back to the time when the matter of this work was first referred to you, Doctor. Can you tell about when that was? A. The earliest recollection I have is late in the summer of 1939.

Q. And was that in a conference or by letter, do you recall? A. Just in a conference and discussion with Mr. Chamberlain and Mr. Rebbeck.

Q. And thereafter what, if any, tests did you make prior to the time you made these pipe tests in which you built the duplicate Menaul tank? A. Well, I made no tests before we started in on this large scale work. The discussion that I had with Mr. Rebbeck and Mr. Chamberlain was that in connection with this case that Dr. Bartell had certain things to perform, and one of the jobs that somebody had to do was to make something other than a little piece of steel in a beaker, and run some tests to indicate what would happen in an oil well tubing under conditions that should be fairly well reproduced, and reported, and that would fairly well represent what might happen in running down the tubing of an oil well, and that these tests also should include an examination of just how this Menaul

process functioned, and what part of the reduction of corrosiveness was due to the Menaul process.

Q. Well, now, in your direct examination, you referred to three different kinds of tests, as I recall. Two of them were laboratory tests, one set of which used little strips of iron, and in the other set of which you used one-inch sections of this same oil well tubing which you used in the larger tests. Now, in respect to time, what was the relation between your laboratory tests and your large scale tests? A. The laboratory tests that we finally adopted, and which are reported in the report as being comparable with the large scale tests employed a time of three hours for the test, and the time of the large scale tests was three hours.

Q. Well, that is not exactly what I had in mind. I am trying to get fixed in the court's mind the relative dates on which you conducted these three different series of tests. The two laboratory series and the large scale? A. Well, we started in to run the large scale tests and—those were the first tests we ran—and associated with the large scale tests we started testing the inlet acid with this laboratory test, using a very small specimen of steel and a very small volume of acid for a very long time of contact, thirty hours.

Q. And then, as I understand it, your first laboratory tests were made in connection with the acid you were using in the large scale tests? A. That is correct.

Q. I see. Now, before you started this large scale test work, did you outline any program and submit it to the members of the Dow organization who were interested in this matter? A. Following the first talk that I had with—there may have been more than one with Chamberlain and Rebbeck—they had indicated about in general what their problem was and they questioned whether Dr. Bartell, with the time available, and so forth, would be able to get around to make these large scale tests. I think they had that in mind when I first talked to them, that he would do the large scale work and the small scale work as well, that is, the analytical work. And, as I recall, they expressed some doubt as to whether he would get around to do it. And I

said if they wanted me to and thought it advisable that I would be glad to undertake those tests. And at the final meeting of those preliminary discussions they said, "Well, you write up what you think ought to be done and let's talk it over again."

And I wrote that up and that is included in this complete file of correspondence, a complete outline of what I thought ought to be done to examine, to ascertain and determine the reduction in corrosion caused by copper and lead in acid, in passing through a piping system, in determining whether the Menaul process had any effect on reduction in rate of attack of acid upon steel, whether the effect you obtained with a Menaul tank was a combination of the inhibitor effect plus the Menaul effect.

And the tests that were outlined included first a running of blank or fifteen per cent commercial hydrochloric acid through a fairly good length of oil well tubing. Second, to run the fifteen per cent acid into this simulated Menaul tank, agitate it for some time that would roughly approximate what agitation would be obtained in handling the acid from the storage tank to the well, and then operate the Menaul process on that acid, that is, to deliver the acid into the tubing and connect the wire up from the tank to the tubing and see what effect that had upon the rate of attack, whether it was reduced over the raw acid that went in without the Menaul tank.

And the next type of test was to run the acid from a stoneware crock directly into the Menaul tank and immediately out, so that we would eliminate this inhibitor effect and we would get only this electrolytic effect, the Menaul method of inhibition, electrolytic inhibition, acting to stop the acid from attacking the tubing.

And the last test was to be a test in which we would take fifteen per cent hydrochloric acid and incorporate into it the metallic concentrations which the acid had when it left the Menaul tank in the Menaul test and we would run that acid directly from the stoneware crock into the tubing.

Those tests were all outlined. And at the beginning of

the work, at another visit to Midland, that proposal was discussed and, as I recall, Chamberlain was the only one present then. He may have talked to Rebbeck. But he said go ahead with the work, and so we went ahead. The first thing that we did was to purchase a number of lengths of this oil well tubing. We purchased a convenient size stoneware crock which was about 250 gallons, and which was so big in diameter and about so tall (indicating), about four feet in diameter and maybe four feet tall, and we purchased the smallest size of oil well tubing simply so that we could get a fair rate of flow of acid in the tubing.

If we used two inch tubing or three inch tubing the acid would have been very slow in running through that tubing, and then the inch and a quarter was taken as the smallest standard commercial oil well tubing that we could obtain.

Now, we had in mind at the beginning of these tests that if we purchased the tubing from one lot of tubing that the attack would be fairly uniform. That is, that if we had one length of tube here with acid running through it it would attack that length at a certain rate and the next length would be attacked substantially the same. And we proposed, with that in mind, as I recall, we purchased 30 tubes with the idea of using 5 tubes in each of these 5 different tests, and then have some tubing left over for making elbows and connections and to cut up for inhibition tests, and so forth.

Q. May I interrupt you there, Doctor. The tests that you outlined in your testimony were five in number—the ones that you outlined as you have just described them? A. There was a raw acid, there was a Menaul process, there was a quick Menaul process in which we ran the acid immediately in and out, there was a Menaul without the wire connected, and there was a synthetic Menaul type acid—five different tests were proposed.

Q. And your original plan was to run each of those tests in a separate set of tubing? A. In a separate set of tubing. We thought the tubing would all perform exactly the same.

Q. And you originally bought enough tubing for the five tests? A. To run the five tests and have enough left over.

Q. Now, will you go on with your explanation? A. Now, we knew, of course, we had to adopt some fairly standard conditions of running the test and we had heard, as I recall through Mr. Rebbeck, that tests were being made at 85° F. by Dr. Bartell in inhibition, and it seemed to us it was a fairly good temperature to use. I don't think it was given any great amount of consideration because it seemed like a reasonable temperature and one we could obtain fairly readily in our laboratory. The tubing, the temperature was fixed in that manner, the volume of acid was fixed by this stoneware crock we had, and we simply arbitrarily decided that we would run through a gallon a minute and would get a test of about 3 hours.

Now, if you question the condition as to the three hours, one of the letters introduced here indicates that I knew the acid treatments that were made by these people were 3 to 25 minutes, or 6 to 25 minutes, but I knew that after the program was about 50 to 60% completed and I couldn't go back and do that over. There were many reasons why I couldn't do that over.

Q. Doctor, aren't you misquoting that letter? A. I don't recall. It was a short time.

Mr. Owen: It is set forth in one of these letters, I believe, and I want to get that right. Yes, it is set forth in the letter dated January 24, 1941, to you from Mr. Rebbeck, which is in evidence as DX-222. Now, in this Exhibit DX-222, the times are given as follows, summarized: Stella Wilcox No. 3, 25 minutes. Zahn No. 2, first treatment, 3 minutes. Zahn No. 2, second treatment, 5 minutes. Those were both one treatment, Your Honor. It was two sections of one treatment. Crawford No. 5, 145 minutes.

Q. Well, now, will you proceed? A. I did not pay a great deal of attention to that letter, simply because we had filled out most of our program on three hours, and I had felt that taking a three hour result would get approximately

what was done in shorter or longer times. We knew that we could not run a three minute test, because we got this peculiar effect of loose powdered metal that we could not remove from the surface, that came out during the first few seconds of the run, and we got a peculiar result there that we could only explain by imperfect cleaning of the tubing. On a run of a 3 minute test, the acid is actually—one particle of the acid was running through our tubing, and taking 10 minutes to go from the inlet to the outlet, so that it would be impossible for us to run a 3-minute test and get any significant values.

We did, however, study quite thoroughly later in the laboratory the effect of time upon the rate of attack of the acid upon oil well tubing, but that came later, and that came after Rebbeck's letter about the time of contact.

I knew nothing about the time of contact before that time, and the basis of the three hours was simply knowledge—I had been out on acid treatments, and hung around for six to eight to twelve hours waiting for the acid to go into the formation, and the general knowledge that I had of the various time that acid treatments required—I had that general knowledge, and the three hours seemed to be a fairly reasonable figure, and fitted in with the equipment that we had, the volume of the crock, and the diameter of the tubing.

Q. Doctor, I show you a carbon copy of a letter dated January 28, 1941, addressed to J. W. Rebbeck, and signed in typewriting by C. F. Prutton. Will you state whether you wrote such a letter? A. I did write this letter.

Q. And state whether or not that was in reply to Mr. Rebbeck's letter of January 24, 1941, which is in evidence as DX-222? A. That is in answer to his letter in which he mentioned the short times of contact.

Mr. Owen: Now, I will ask that this letter—

Mr. Lyon: May I see it?

Mr. Owen: You had it. It was right in a bunch of letters you had this morning.

The Court: PX-228 this will be.

(The letter above referred to was thereupon marked PX-228.)

Mr. Owen: Will you explain that letter, reading such portions of it to the court as may be necessary to explain the sketch that it contains? The date is January 28, 1941.

The Court: With such a short letter you might read it all.

Q. Read the whole letter.

The Court: And then explain it. A. (Reading):

"Dear Mr. Rebbeck:

"Our 3-hour tests duplicated fairly well the time of 145 minutes required on the test on Crawford No. 5.

"However, we have no large scale tests made in from 3 to 5 minutes such as occurred in tests on Zahn No. 2. Moreover, we cannot see how a 3-minute test could be made with our set-up. However, our laboratory tests show that during a test of short duration, such as 3 to 5 minutes—"

we took this and put it only for a few minutes into the acid to see how the amount of iron dissolved compared with what would dissolve if we used the chemically pure acid—

"* * * the percentage inhibition would be about the same as would be obtained in the 3-hour test.

"The rate of solution of the iron is greater in the short test than in the 3-hour test."

The Court: You better read that to me. A. I will read the whole thing.

"If you think that test on our laboratory tests which we have shown to agree quite closely with the large scale 3-hour tests would be sufficient we will re-check our preliminary figures and short-time laboratory tests to more exactly establish the above curves. If you think it imperative to run large scale tests please advise me and we will attempt it."

The Witness: Now, the letter shows a drawing, or a graph, which shows plotted horizontally the time of contact in this laboratory test, 180 minutes, which is out at the end of 3 hours. The rate at which the acid ate into the steel, expressed in grams of iron per square meter per hour is plotted vertically. And it shows that in the first few minutes of the 180 that there is a peculiar sharp dropping of that curve.

Q. What does that indicate? A. That indicates to me that that is that loose metal which we got on our large scale runs, or metal which is highly disturbed on the surface of the steel that simply wiped off by the first acid attack, and it is difficult to run a test of such short duration to get a valid answer. As soon as you go to a period of 8 to 10 minutes, then the curve becomes almost flat, and they show, the upper curve uninhibited 15 per cent C. P. hydrochloric acid.

The rate of attack of that is about 70 grams per square meter per hour and it eats into the steel at that rate. The rate of attack of the same Menaul acid is about 25, in other words, about one-third the rate of the inhibited acid.

In other words, going from 8 minutes out to 130, and we in subsequent work that is in that book that we had, our data book, we went out for 12 to 14 hours too, and those lines just kept on going out. We believed that that would fall off when you went out to a considerable number of hours, but from the period of 8 to 10 minutes and going on out through our 3-hour test, the reduction in corrosiveness, of the Menaul synthetic acid was only about one-third as corrosive as the diluted C. P. acid, and therefore this letter, I believe, convinced Rebbeck, or at least I don't recall he wrote me another letter telling me to go ahead with large scale tests. This indicated the impractical nature of it, and also that we were running short of time, and so forth, and I don't recall any other correspondence on that. That seemed to close the matter up.

We did run checking values to check these preliminary data that we have, and we have data that will establish the curve from three minutes on out to fourteen hours or so, and the curve is substantially of that shape, showing that the reduction in corrosiveness is substantially constant after ten minutes time, and we believe that that first part is due mainly to these little particles of iron that when we run our wire brush through the steel that those little particles of iron are just held on there by a thin piece of connecting iron or something, and any attack at all loosens it

up. We got a slug with highly concentrated iron out of the large scale tests, indicating that to be true.

Q. Go ahead. A. That time was one of the conditions of the test. Then we realized that the method of cleaning the tubes undoubtedly would exert a great effect upon the test results. In other words, the scale, and so forth, on the surface, that we had to adopt some standard procedure, and so in Test A we set up five lengths of tubing with an extra part to connect it up to the top, and then coupled it, and we had—we purchased this stiff, hardened steel wire brush, and fastened it on the end of a long iron rod, and one of the operators that was to make this test, one of them was assigned to the job of cleaning out this tubing, and after he had done it he insisted that we put another man with him, or two other men, and we used three men to get that brush, which is, when extended, about two and a half inches in diameter, to ram that through an inch and a quarter tubing. It was a stiff wire, almost like piano wire, and it took two or three men to get that through and to do it in a reproducible manner. But he finally got it through and ran it through twice, which was the number of times that we used in later tests in the remaining use of the tubing.

Now, the rest of the method of the cleaning was essentially the same as we used in subsequent runs, but he just took a tremendous length of time and was all tired out after the cleaning out job, and, therefore, we later assigned two or three men to that, and we didn't feel particularly perturbed about the test because many things happened during that test.

In running the acid out of the crock, and coming down into the tubes, we left a vent there that would extend up above the level of the acid in the crock, so that any hydrogen generated or liberated by the attack of acid on the tubing would bubble back up and come out of this glass tube, and what happened was that it was like a fountain, that the bubbles would come back and the acid would squirt up into the air, and it scattered over the equipment, and I don't know how many gallons of acid were lost in the test, pos-

sibly one or two, but it made kind of a mess. So we had to modify the equipment in that respect.

The other differences in Run A were the shape of the tubing. There was one welded fitting which made two of the pieces of pipe welded together, which we never used in any other run later on, and we used—we numbered each tube we purchased, and we used tubes 1 to 5 to run A and we never used those tubes again in any other subsequent runs.

Q. Will you identify that run with the five runs that you have outlined in your program? A. That run was supposed to be a blank run, or a run of raw commercial acid through the tubing.

Q. And what letter was given to that run when it was made? A. In our data book, it was given the letter A, first run.

Q. Can you show to the court the set-up of the tubing used in that run? A. Yes. If I may have that preliminary report? It was not included in any subsequent reports.

(A volume was handed to the witness.)

Q. Will you just explain how that set-up differed from the one that was later adopted and used in all of the tests referred to in your report, in your final report? A. This had four lengths of straight tubing, and subsequently we used five lengths of straight tubing—is that correct, Mr. Lightfoot?

Mr. Lightfoot: Yes. A. But we had this peculiar bent piece of tubing here, (indicating), which we hooked up. Oh, we did not use that tubing for any further work. We then went to this set-up which involved the lengths of tubing and this long length of tee here (indicating). We could use that with Menaul test tanks as well as the other types of tests which we ran directly from the stoneware crock (indicating). This is glass tubing down around this here (indicating). There is a rubber stopper connected on to that (indicating). This elbow at right angles was used in subsequent tests.

Mr. Lyon: I think this had better be marked, the first one that you referred to, as PX-229.

Mr. Owen: And the second one as PX-230.

(The figures above referred to were then marked PX-229 and PX-230.)

Q. I am going to remove these from the preliminary report. Now, Doctor, this set-up that is shown in the second of these figures, which is PX-230, was that used in any of these first five runs? A. That was used in all subsequent runs that we made.

Q. That is, in all those that you made from the stoneware crock? A. Yes. Should I go on with the description of this?

Q. Of that run A. I want you to tell all about that run A, which is not included in your final report—that is true, is it not? A. Yes.

Q. I want you to tell all the reasons why you did not include it in your final report? A. The analysis of the samples of acid entering the tubing system and leaving the tubing system, were turned over to one of my assistants—I believe it was Mr. Riehl—was it not?

Mr. Lightfoot: Yes. A. And without any great specific instructions as to how to make these determinations. And we had in the same laboratory, right opposite his office, a graduate student who was using the orthophenanthroline or colorimetric method for determining acid in low concentrations. And this man Riehl took these samples and ran them by the orthophenanthroline method. I think some of the samples in one or two of the other runs were run by that method. But when we finally adopted our standard method of volumetric procedure, we did not go back and run any of the runs of run A, because we thought that it was not worth while, and I will explain further along that line.

Another factor that entered into the thing was the iron content of the effluent acid showed a great falling off during the run which wasn't particularly noticed to any great degree in the subsequent runs with raw acid. And I would like to give you those figures. Do you have that run A Mr. Lightfoot, to show the falling off in iron content?

(Mr. Lightfoot produced document.)

The iron content ran from 1.055 milligrams of iron per c.c. It went up to 1.15 after the first sample was taken, then started on down to 1.075 but the last composite sample taken was .525—more than a 50% falling off in the iron content. Now in later blank runs that we made, that is, using the raw acid through the tubing, we had changes, as we mentioned heretofore, but they were not of that order of 50%. They were a slight change. For example, the first composite sample in run 1A blank 1350 parts per million of iron, the second composite 1450, and the third 1405. That is a variation of about 25% maximum variation in the composite samples analyzed, and we had over 50% in that one which indicated that something had happened. I don't know what.

Q. With that colorimetric method of analysis, what did you find out about it in connection with these tests? A. I knew all along it was to be adopted only for small amounts. The man who did the work, evidently the student was using orthophenanthroline and he picked it up and used it. It is supposed to be used for minute concentrations of iron.

Q. It was not appropriate for this use? A. Not appropriate for this particular run. Now, we did run later on the gravimetric determination and one or two samples from 1A and they checked within about 10% of the figures that had been obtained from the phenanthroline method, but evidently the method isn't too accurate for great amounts of iron. These were very high concentrations.

Q. And then you adopted what? A. And then I talked to the man and took him off this colorimetric method and put him on the gravimetric method. That worked all right until we got to the high lead concentrations, but it worked very well for blank runs.

Q. And then when you discovered that the gravimetric method was not suitable for analysis of acids containing lead and iron, you dropped that and went to the volumetric method for all? A. We ran back all the valid

samples. We got all the samples from the valid runs and repeated the analysis on all of them by the accurate method.

Mr. Lyon: Just one moment. I was looking for that original book that we had yesterday, that had all of this data in it. A. Mr. Lightfoot, do you have that?

Mr. Lightfoot: Yes. A. Open it up to the page where the data is.

Mr. Owen: When you purchased these thirty sections of oil well tubing did you mark them in any way so as to identify them? A. We marked at least 28 lengths of tubing with a definite number that was kept on that tubing from then on.

Q. What were those numbers? A. From 1 to 28.

The Court: You described two or three methods? A. We described three methods.

Mr. Owen: Which ones of those sections were used in this set of tubing in which you ran your first run, A? A. In run A we used tubes 1 to 5.

Q. Were they ever used again? A. No.

Q. What became of them? A. Well, we started out on the premise that we were going to use one set of tubes for each run, because we thought they were all uniform, and after we had run five tests and consumed all of our tubes we found that they weren't uniform, and came definitely to the conclusion that we couldn't run different tests on different sets of tubing, we had to run different tests on a similar set of tubing, and any comparisons—

Q. (Interposing): You had to run comparative tests on the same set of tubing? A. After giving them a standardized cleaning procedure, which eliminated and presented a new surface inside.

Q. Were any of these first five sections of tubing used in your smaller tests, your laboratory tests? A. As I recall it, several of those lengths were cut up into the corrosion test specimens that we used for later work.

Q. Now, I call your attention to Figure 2 in PX-184, which was identified as PX-174-A, and will ask you to compare that with the last exhibit, PX-230, and point out any

differences between the PX-230 and PX-174-A, both of which show your set-up using the stoneware crock. A. I would like that other figure.

The Court: Here. Is this it? A. These figures are identical as regard the set-up. Starting at "Y" is the steel tubing elbow that we made up with the long side arms on it, welded together, and starting at "Y"—

The Court: You are comparing PX-174-A with PX-230, and not with 229? A. That is correct. This long elbow,—it really was a "T," because at one side, extending down here, we had a rubber stopper in there, and that section form was used in all of these crock runs. Down below here, the end of the straight lengths of tubing, there was a rubber stopper inserted, and I have described that, that had this 1-inch Pyrex tube.

Q. That is in 230? A. Yes, which led out of the end of the tube, past the screw clamp, and into this metering bottle, and we could adjust the flow by means of that screw clamp, and the height of the acid in the bottle indicated the rate.

The Court: What was the object of putting these joints in and not having it to go straight down as it was in the well? A. This set-up has a height of 12 or 13 feet from the top to the bottom, and a total length of one hundred twenty some feet, and we had to take the laboratory, we had to work it around through a door from one lab over to another, and it had to go around a corner.

Mr. Lyon: You could look at this drawing, and the beginning of this was at the top and the other at the bottom and it flowed vertically, but as a matter of fact there was a little incline? A. Slight incline. It was about six feet in a hundred.

The Court: It is all more horizontal than it is perpendicular, I remember that. A. Yes, but these PX-174-A and PX-230 show identically the same system of tubing arrangement and set up used in the run E, which was our fifth run, and the later runs with the raw acid directly from the crock through the tubing system.

Q. Well, using any acids? A. Yes.

Q. Either raw acids or synthetic acids? A. Or synthetic acid from the crock through the tubing system.

The Court: Now, why do you tell me that the apparatus as it was in 229 was any different in result, why would it be any different? A. It would differ but slightly in that this was a short length, it was shorter in length than that, and it was bent around at that angle. We did not have a "T," but this peculiar bend.

The Court: What difference would it make? A. It would make a slightly lower amount of iron dissolved because it is shorter tubing length, and the other difference—

The Court (interposing): But the bend, would that make any difference? A. It wouldn't make a great deal of difference, only that there is a little difference in construction. This tube, which was glass, at the start of the run was open, and that is where the slugs of gas would come up, the hydrogen and slugs of acid would squirt up in the air. So shortly after the run was started and they had acid spilled all around, they connected a rubber tube to the glass tube to get it back into the tank, to prevent it slopping.

The Court: The real reason as to whether or not the bends would make a difference or not, you do say it would make—might make a slight difference— A. (Interposing): Slight difference; not a major difference.

The Court: I would say so far as there are any bends in it, it is different than a well construction. You see the thought I had in mind, Doctor. A. It wouldn't make any great difference.

The Court: All right. I think right there I will ask you, the slight difference, which way would the difference be, the bend, that it would make more corrosion or less corrosion. A. This is an opinion. It would be my opinion that corrosion is increased with greater turbulence, and a right angle bend produces more turbulence than a gradual bend, so you would get slightly greater corrosion with that right angle bend than you would with a bend that came across at 45 degrees, but it wouldn't be a major factor.

In other words, if you pass water around a corner in a pipe or elbow, that water tries to go straight ahead, and it churns up on itself, and if you had acid in the steel pipe that churned up, or turbulence at the bend, it would tend to attack the steel and wipe off that coating.

The Court: It would at one place. I am thinking of the creek and the effort it makes to go straight ahead as it makes a curve, wherever there is a bend it has a tendency to go straight ahead. A. Go ahead.

The Court: Straighten it. We find a greater corrosion at one place, and we find sediment and lack of corrosion at another place. A. This doesn't form sediment, because it forms soluble iron chloride that stays in solution. I don't think it is a major factor.

Mr. Owen: What was the rate of flow through the pipe in these tests? A. The rate of flow, that is the first time we used this rate of flow control, and it varied considerably during the run. We had never adjusted the rate of flow controller before, so it was—there was considerable variation in the rate of flow during the test.

Q. During all the other tests that are in your final reports, the rate of flow was what? A. That was adjusted at one gallon per minute, and we attempted to adjust this first one to one gallon per minute, but the operators were not as skilled as they became later on.

The Court: By the first one, you mean Run A? A. Run A, which was not reported.

The Court: And that is one run? A. Yes.

The Court: Well, when we come to the final results, you ran more than one, didn't you? A. Oh, we ran eighteen total runs.

The Court: But with each pipe—five each, I thought. A. Five or six with the same tubing, with the same number tubing.

The Court: But with this first tubing you only ran one? A. Ran one.

The Court: Discarded that? A. Discarded the tubing. Because we figured we were going to do that in the beginning.

Q. Now, the next one, which you originally marked B, followed the one that you have just described, is that right? A. That is correct.

The Court: In other words, the one he has just described was used with— A. (Interrupting): Raw acid from the crock.

The Court: I wanted to get that number.

Mr. Owen: No. 229, run A was used on that. A. Oh, yes, run A.

The Court: And B was PX-231. Is that right? A. Yes.

Mr. Owen: In the subsequent runs he used PX-230.

The Court: PX-229 was the one that did not have the right angle corner—is that correct? A. That is correct, yes.

The Court: And the one with the right angle corner is PX-230? A. Yes.

Mr. Owen: Will you explain that second run? A. The second run, or run B, was a test in which we took our polarized Menaul tank and connected it to the tubing system, and then at a higher level with it, this stoneware crock, and in the stoneware crock we diluted commercial acid about 15 per cent concentration; and then we tried to run that into the tank, the Menaul tank, and immediately run it through the tubing, with the idea that—

The Court (interrupting): Oh, I remember that one, and you got an average rate of an hour and a half. A. In that tank, and we picked up quite a bit of lead, and we got some inhibition.

The Court: You figured that was about an hour and a half, but it was not definite? A. Yes.

The Court: But it was not definite? A. No, it was not definite.

The Court: It wasn't three hours, and it wasn't any hours? A. No.

The Court: You tried to get a test without staying in there at all—. A. So that there would be no lead or copper picked up from that tank.

The Court: You figure what you actually did was to get an average of about an hour and a half in that tank? A. About an hour and a half in that tank, and we got about one and a half parts per million of copper, and about half as much lead as copper, and we got about half as much inhibition; but the thing we did wrong in this particular test, due to our ignorance, we thought the tank would not corrode very much, but we took only two samples out of that Menaul tank—we filled it up with acid and immediately started running out of the Menaul tank into the tubing, and we took a sample at the beginning, and one about half-way through, just two samples, to try to give us a figure as to the iron content. We thought it would stay fairly low, and when we got through, we found even with two samples, instead of being saved separately, they were blended together to make a composite, and that composite showed 457 parts of iron, or some value like that, about a third as much as was found in the Menaul tank acid later on, indicating—is that correct?

Mr. Lightfoot: Yes.

A. The commercial acid when diluted has only contained five or ten parts per million of iron, and, therefore, after the acid got into the tank, the first sample was probably close to five or ten. The other sample taken half way through the run, when it was blended in equal proportions with the first sample, showed four hundred and some parts per million of iron, indicating that it was a tremendously high concentration of iron.

Now, we did not want to use any figures of iron content where it was changing rapidly, based upon a composite of two samples. We did not think that was an accurate way of doing things. And also the test indicated that it was impossible for us to do the thing we started out to do which was to separate the electrical effect of Menaul from the chemical inhibition effect. In other words, we ran a Menaul test with the wires connected (that is the next test) duplicating Menaul process, and we figured we would get electrolytic protection by the Menaul method, if any, plus the

chemical inhibition effect. Then if we run this acid through so rapidly we would just get the electrical effect and we could measure the proportion of each.

Mr. Owen: That is, you wanted to get the effect of the acid as it existed in the Menaul tank after 6½ hours being stirred periodically, and didn't want it to take up any more lead, copper or iron before it ran through the pipe? A. No, we wanted to run a Menaul test putting the acid in the Menaul tank and agitating it for six hours to get metals picked into it, and then run it through our tubing system. Now, we felt that in that test the protection of the tubing from the acid would be caused by two separate effects. First, any metallic inhibitors; second, the electrical effect claimed in the Menaul patent. So that is a combination of the two effects. And then this separate test, which was run as test B, was to try to separate the electrical effect completely from the chemical inhibition effect. It did not succeed because we got inhibitors in that acid during that rapid pass through. The rate of attack of the acid upon that Menaul tank was so great we didn't take enough samples in order to accurately indicate how much iron was in the acid when it entered the tubing, so we could figure the difference across the whole run.

The Court: Wasn't there any way to let your commercial acid run into your pipe without going through your Menaul tank? A. Yes, and we did that in later tests. But we wanted to give them the benefit of the doubt of having actually a lead electrode connected in there. To give them the benefit of the doubt to get a lead electrode connected in there, and we couldn't run it by the lead electrode in the steel tank fast enough so it would not pick up lead and copper from the tank.

The Court: Have you yet devised a way so you can separate and say how much is due to the inhibition in the acid no matter how they cla a it, the inhibitors in the acid? Is it the sort of a problem you can't unscramble? A. No, we did solve that. In other words here we measured a combination of two effects. To do a real complete job you

would measure each job separately and see if they measured up to the total sum of the two.

The Court: How are you going to measure them separately? A. I will come to that. This attempt we made here was to get the electrical effect separate, and it didn't work.

The Court: I see. A. Now, to measure the chemical separately, we prepared the acid in the stoneware crock with added chemicals and ran it through the tubing and duplicated the composition.

The Court: Did you let it keep on working while you were using it? A. This is a later test.

Mr. Owen: This was in the stoneware crock. A. In the second test we tried to get the electrical effect and could not get it, but the fifth test we ran was a test in which we measured the chemical part alone and the chemical part was equal to the total of the two, see.

The Court: You measured the chemical part in what way? How did you get that? A. By simply preparing this acid with the same concentration of added metals as the acid had in the Menaul process, leaving the Menaul process, going to the tubing and we didn't put the electrode in. When the chemical inhibition leaving from the stoneware crock, going directly to the tube, and the inhibitor gave us the same result as the total of the two, we figured the electrical effect was zero. If it hadn't been zero we would have been quite puzzled as to how to proceed.

Q. And in that run you have just described, and which was identified as run B, you used the equipment as shown in Figure 5 on page 17 of PX-185? A. Yes, that is correct.

Mr. Owen: I think Your Honor saw that. The stoneware crock is above. The acid was put in the stoneware crock and then run down from that crock into the Menaul tank.

The Court: Is that different from PX-230? A. That was the Menaul tank.

The Court: Oh, yes.

Mr. Owen: And 230 doesn't have a Menaul tank.

The Court: That is right.

Mr. Owen: Now, your run B is one of the runs that was not incorporated in your final reports? A. That is correct.

Q. Now, proceed and explain your third run, which was identified as run C. A. Run C is reported in the report as 1-N.

Q. That is in PX-185? A. As run 1-N, and we used in that run tubing numbers 12 to 17.

Q. Oh, I did not ask you, Doctor, what sections of tubing you used in that run B? A. In the run B we used tubing numbers 6 to 11.

Q. Were they used again? A. They were not used again.

Q. Your third run, C? A. Was 12 to 17, and those were run—and those were designated as Series 1 tubing in this test.

Q. And so referred to throughout your report? A. Yes. In this test, this test was a Menaul test, and to just give you the brief elements of it, it is reported in the report. The acid was prepared in the stoneware crock, diluted to fifteen per cent, checked for analysis and inhibition, and then run into the Menaul tank and agitated for about six hours with this periodic agitation, to duplicate or give some manner of equivalent action to the rattling of the truck over the roads, the shaking that it would get.

The Court: When you say that acid was checked, you mean you checked it chemically? A. And by running the inhibition on the third laboratory specimen, or, rather, the little laboratory specimen. We ran both the chemical analyses, and it showed a very low copper and lead content and the inhibition ran from zero to 6½ per cent, of all the acids used.

The Court: What are you comparing that to? A. That is just a small laboratory test.

The Court: Well, I know, but six per cent of what? A. Six per cent reduction. I would like to go into that very thoroughly just a little later.

The Court: But one reason we haven't any standard way, we not only haven't any standard here to go back to the old thing about the conditions, but we haven't any standard as to where we start, either, have we? A. We have a standard—

The Court (interposing): You can fix one, I mean, but another fellow will take another standard. When we take one hundred per cent, nobody knows what that means until they tell. There isn't any standard here, as a starting point, as to percentage of inhibition and percentage— A. (interposing): The starting point is the rate of attack of C. P. hydrochloric acid.

The Court: You have got to go on and tell me under what conditions. A. I know that.

The Court: So there isn't any one hundred per cent.

Mr. Owen: We had to make our own standard.

The Court: Sure. I didn't want to emphasize the corrosion thought I had.

A. In this test, and that has been completely reported and discussed in detail—

Q. Yes. I don't want you to go into that again, Doctor.

The Court: When you found one hundred per cent or six per cent, was that the figure you used, six per cent? A. All of the acid we used, our commercial acid, diluted to fifteen per cent, shows values of zero to 6½ per cent, if I may use the term, inhibition.

The Court: What I want to get at, what did you take as the six per cent of what? A. We took a single piece of steel and tubing and put it in a certain volume of acid.

The Court: Pure hydrochloric acid. A. Fifteen per cent C. P. acid.

The Court: And under the same conditions you put the commercial in. A. That is right, and the rate of attack was within six per cent of the C. P. acid.

The Court: All conditions were exactly alike. A. That is correct.

The Court: Except that one of them was HCl. A. C. P. pure.

The Court: Pure, and the other was whatever you had. A. Commercial acid in that tank.

The Court: All right. Now, I have got it. A. Now, the next run, run D was run—I might mention in this run C—

Mr. Owen (interposing): Your run C that you have just referred to is run 1-M in Table 9 of PX-185? A. That is correct.

Q. Now, will you describe your next run, run D? A. Well, run C, as I mentioned—this is going back to C—is the Menaul tank in which we connected a wire between the tank and the tubing as taught in the Menaul patent. Run D is numbered 2-N and is reported in the report and used.

Q. In report PX-185? A. 185. We used tubings numbered 18 to 23 in that particular run. The number of the tubes were 18, 19, 20, 21, 22 and 23.

Q. And that became your Series 2 tubing? A. That became Series 2 tubing. In that test 2-N we did not connect the wire in the Menaul process. We did not connect the wire. That was the only difference between run 1-M and 2-N. The "M" means Menaul, and the "N" means "No wire."

The Court: That is, no wires connected? A. So we had four runs that we completed at that time, and we went back to run B, that is the quick Menaul test, to see if we could not do it the second time. We hadn't got complete enough data to calculate it the first time.

The Court: Is that run B? A. Run B, so the 2-B was the check on B, and we used tubes No. 24 to 28, on that particular run.

Q. Were those tubes used on any other run? A. They were not used on any other runs.

Q. Well, now, explain very briefly this run 2-B. A. On run 2-B we had all of the iron data, and the inlet acid—

The Court: Could we call that "D"? A. That was not even reported.

Mr. Owen: It is 2-B.

The Court: It wasn't reported? A. It wasn't reported. It isn't in here (indicating).

The Court: I have got A and B, and they are not reported in here, so that doesn't seem to be a reason for eliminating this. A. A and B were not reported at any time. In test 2-B we got the data, the correct number of inlet samples at different times to run the iron on and other metals. We also got the exit samples sufficiently enough to calculate the amount of iron that was picked up in going from the end of the tubing in the Menaul tank over to the exit; but the samples showed a considerable amount of lead and copper, just as we had obtained before, and the amount of iron that dissolved was somewhat less than the amount that was dissolved in run A, in which we had just put the raw acid through.

In other words, we got about the effect that we expected after run B, that if these metals were in there, in checking run B and running it into the tank and taking it out as fast as we could, that metals were picked up which gave it some inhibition in going through the tubing, but it did not determine the thing we were after.

The thing that we were after was to get a clear cut separation of the metallic inhibition from the electrical inhibition. It did not give us the electrical effect alone, and therefore we discarded both of those runs.

Mr. Owen: Now, you have made five runs, and you have discarded A, B and 2-B; is that right? A. That is correct.

Q. Now, will you go o and describe run E, please? A. Now, Run E, at about that time we came to a definite conclusion that we had to, if possible, use, select certain tubes and run the whole series of runs through those same tubes, giving them a standard cleaning out in between each run. That apparently we could not check between runs made on one tubing system under one condition and runs on another.

We had losses of weight, for example, in all of these

runs, we had losses of weight in each piece and each fitting in each of these runs, and they would show variations of 20 per cent, and, therefore, we wanted to use the same tubing and run a whole series of comparative runs through the same tubing system, and so after the first five tests we looked over the data and we picked out two sets of tubing so we would get a check on a series run on one set of tubing and a series run on a completely different set of tubing.

We picked out two sets of tubing that had been run in two of the valid runs that we had made. Now, there were only two good runs out of the first five, because in run A we had this trouble of the varying of many conditions, and the blank, we didn't think that was very good, and, as I recall, at the time when we completed the five tests some of those lengths of tubing had been cut up to make corrosion samples, and so we couldn't run that one or didn't think it desirable.

Run B gave us this indeterminate result that would not clearly separate the electrical effect from the chemical inhibition. 2-B was the same. But runs C and D we felt were valid runs. So we picked the tubes out in those two runs, and decided that we would run, in different order, this sequence of tests that we had outlined.

We eliminated this quick Menaul method, however, in subsequent work. We decided we couldn't do that, because we had tried it twice and failed, and, therefore, we started to run a series of runs using the No. 1 Series tubing.

The Court: 12 to 17.

A. 12 to 17 is the Series 1 tubing. And that had been used in the Menaul test which we had used the standard—

The Court (interposing): You had to renumber it in order to make it Series 1. A. That is right, change the letter designation.

The Court: Yes. But— I see, all right. A. Yes. And then 2-N which was reported, which was a no-wire Menaul test, we figured was a valid test, and the tubing used in that was 18 to 23, and we just called it Series 2 tubing, and that is the reason—

The Court (interposing): 18 to 23, inclusive. A. 18 to 23 is correct. So we did not try any of these quick Menauls any more. We started in our series of running the tests as outlined, dropping out the quick Menaul test.

Q. Explain now your next run, which is Run E. A. Run E was a blank or a raw acid run from the crock, using No. 1 series of tubing.

Q. And that is Run 1-AA in PX-184, is it not? A. That is correct.

Q. That is your Table II? A. That is correct.

The Court: What do you call that? A. 1AA.

Mr. Owen: Now, you explained at the outset, Doctor, that you planned to run five different runs and you have now explained six runs. A, B, C, D, E and 2B. Now, I will ask you regarding your Run 2B, the other 5 runs corresponded with your original plan.

The Court: Let's see about that. Before you start to talk about A. He has 5 runs, discarded 3 of them and saved 2.

Mr. Owen: That is right.

The Court: All right. Now he is starting in to run a series of 6 runs with 2 he has saved out of the 5.

Mr. Owen: And what I want to bring out now is that Run E corresponds with the first of his original plan. A. Yes, sir.

Q. Which was discarded? A. Which was raw acid. We didn't feel it was a satisfactory one and we didn't have Tube 5 to keep a sequence with. We had the four of the originals but we did not have the fifth section.

Q. Then we are down to the point where you adopted these two series, 1 and 2, for all runs? A. Yes.

The Court: And you are going to use the one you used in C for Series 1, and the one you used in D for Series 2?

Mr. Owen: That is right.

Mr. Owen: Well, we have gotten down to your run E as originally marked, and which became run 1-AA in your report, Exhibit PX-184. Now, take up very briefly run F and state what that was and what it became in your re-

ports. A. May I at this time put in the explanation of that preliminary report?

Q. Yes. A. At the completion of run E a preliminary report was written to be sent to Midland to give an idea as to how this work was coming, and Mr. Lyon has read from some of the conclusions of that progress report, conclusions that were diametrically opposed to what I contended at the completion of the work, and the first thing I would like to do would be to read all of the conclusions, instead of just the one, and then to explain just the picture as it existed at that time. I have here this progress report dated March 1, 1940, and at this time we had completed, and as reported here, all of the runs through E.

The Court: What is the date of this report? A. March 1, 1940, and the heading of the—

The Court: Just wait. As I understand it, this is your report made at the conclusion of the five runs up to E? A. That is correct. There were six runs.

The Court: And you want that called preliminary report, March 1, 1940, at conclusion of experiment E? A. That is correct. And the report is titled "Progress report on Menaul tank," and the heading at the end is headed "General comments."

The Court: All right. A. First, the rate of attack of hydrochloric acid—

The Court: Are you going to read the entire report you say? A. No, just the comments. Mr. Lyon read one of the comments, and I would like to read them all.

The Court: All right. A. (Reading): "The rate of attack of hydrochloric acid on various lengths of tubing seems to vary considerable from length to length and be quite dependent upon the method of cleaning the metal surface.

"2nd, in duplicating the Menaul procedure the amount of inhibition exhibited was much greater than would be indicated by the chemical inhibition shown by the entering acid."

Now, that is the statement that he wanted me to explain. In duplicating the Menaul—

The Court: Read that again. A. "In duplicating the Menaul procedure the amount of inhibition exhibited was much greater than would be indicated by the chemical inhibition shown by the entering acid."

The Court: Which leads to the conclusion, just standing right there, that what had been done in the tank increased inhibition, is that right? A. That is correct. That is what one would get if they read that statement alone. I will go ahead with these comments and come back to "Two."

"Third, when the wire was disconnected in the Menaul method even greater inhibition was obtained," which is a conclusion that we have recorded.

The Court: Read that again. A. "When the wire was disconnected even greater inhibition was obtained."

The Court: Yes. A. "Fourth, potential and current measurements cannot be reasonably interpreted.

"Fifth, loss of weight of iron from tubes determined by direct weighing, which was the loss in weight of iron in Menaul tank, may be completely explained on the basis of chemical inhibition."

I am somewhat at a loss as to that particular comment. We have felt that the analytical determination of iron in solution to be a more accurate method than is implied in the loss in weight method from the tubes, and we use the analytical procedure.

"Sixth, we are completing a run in which acid, duplicating in chemical composition that obtained in the Menaul storage tank in run C will be run directly from the stoneware crock to the tubing, the same tubing used in run C, 2-B and E will be used."

That is the sequence of the tubing.

The Court: Well, that sounds like you are telling what is going to be done in what you had in E, rather than— A. (Interrupting): No, in E we ran simply the raw acid for one set of tubing. We are telling him what we are

going to do in the synthetic run. At the time of writing this report we had no synthetic run. All we had to go on was the comparison of the reduction in corrosion in this Menaul tank.

The Court: That you rigged up? A. Yes, and the raw acid, and we found that there was 75 per cent reduction in corrosion, whether we had the wire connected, or not, over what we got with the raw acid; but on the acid that we fed into the system, the acid that went into this pipe in the Menaul tank,—we had taken samples of that and tested it in the laboratory for the amount of inhibition, simply by putting it in this beaker with a small volume of acid, and allowing it to stand, and comparing how much it had reduced the attack of the acid, that is, the metals that we put into the Menaul tank, so we were comparing the reduction in attack in a large system with the reduction in attack in this small specimen test. And the small specimen test that we used at that time was this, we took a small section—I cannot give you the exact dimensions, but I could look them up, but in general it was about an inch by three-quarters, cut out from the side of a piece of oil well tubing, and about three-tenths to four-tenths of its area was this cut-out edge of the section of the sample.

The sample was cleaned and then immersed in a small volume of acid, and allowed to stand for thirty hours; and when we got through with that test we found that the acid that had been taken from this Menaul tank just before, and during the run, when it was running into the tubing, the acid with the lead and copper and iron it had picked up in the Menaul tank, that acid in this laboratory test had shown between 30 and 40 per cent reduction in corrosiveness only; and, therefore, when comparing in this report with the only data we had,—we had not completed a single large scale synthetic run, we were comparing results on our laboratory inhibition tests with the results of this large scale test, and we have gotten 75 per cent, or plus or minus 10, reduction in the large scale equipment, we have shown that the wire made no appreciable difference in the results,

which also would tend to indicate that there was no—quite definitely that there was no electrical protection, and we got 30 to 40 per cent inhibition on the acid in this laboratory test, and 75 per cent on the large scale test, and, therefore, the only comparison that we could have made now was the comparison of those two figures, and, by the way, it seemed—it simply appeared as though maybe there was something there from that particular comparison.

Now, following this particular progress report, and as indicated in here that we were going to run this synthetic run, which would really answer the thing, because we would have two large scale tests to compare following that run—the run E, we then went to run F, or run 1-B, which was the first synthetic run that we had made, and the date on which we had that run was March 17, 1940. This report was dated March 1, 1940. The first synthetic run that we made was run 1-B.

Q. And that run, as I understand it, was run from the crock? A. Directly into the tubing.

Q. In which you placed 15 per cent commercial hydrochloric acid, and added to it the metals corresponding in amounts to those found in your Menaul run? A. To those found in the Menaul run, 1-M. And we found that with the synthetic acid we got 238 grams of iron dissolved from the tubing, and with the Menaul run 322 grams of iron dissolved. The synthetic from these figures would appear somewhat better but it was at least as good.

Q. Then, Doctor, you go on through your subsequent runs down to Run I and explain them quickly. A. The next run was Run 1A or G in our data book—G or 1A. Now, the purpose of running that particular run and in the order that we had run it was this: We had in Run E run raw acid through the tubing. After that raw acid run we had given the tubing a thorough cleaning out with our standard cleaning procedure and we ran run 1B, the synthetic run. Then we came back and ran a raw acid again to see if the cleaning out procedure we used would take any metallic coating off the inside of the tube and

give us a fresh surface that would be comparable with the fresh surface of the pipe prepared before acid containing the inhibitor had been run through.

Q. This is 1A? A. 1A is our report and G is the letter in the book.

Q. Raw acid again? A. Yes, sir. We found in the first we got 943 grams, the second 1043. We considered that was probably the limits of accuracy of the metal but at least we had gotten a fairly close check on the attack of commercial inhibited acid or diluted acid to 15% strength upon the tubing.

Then Run H, which is run 2M which is reported, was run on Series 2 tubing. Now, we had only previously run 2N or D on that set of tubing so that we had a Menaul method following the Menaul without the wire. The first test made on the series 2 tubing was the Menaul minus the wire. Then we ran a Menaul with the wire in the same tubing after, of course, cleaning it out as described. Then—

The Court: What about the wire? A. The wire was connected. That was the Menaul procedure. And then Run I was to have been a synthetic run and it was run upon series 2 tubing, and it was supposed to have contained after we had added the chemicals to it, the same concentrations of lead, copper and iron that were present in the run 2M.

Q. That is the last one you referred to? A. Yes. Now, that is the one run after we started on this 2 series of tubing system that has been dropped out of the report, and I want to explain that.

The Court: This is I and what is the other letter? A. There is no other letter because it wasn't used in the report. In Run I we calculated the amount of copper salt to be added and the addition was supposed to have brought the total concentration up to about 2.8 parts per million of copper. The number that is written in our data book of added copper salt would correspond to about 2½ parts per million and there was around .3 of a part per million in the original acid, which would theoretically make everything correct.

Now, we ran tests after the acid was blended, the chemicals added. We ran this small scale inhibition test upon a sample of that acid before it went into the tubing. The percentage inhibition shown in that test instead of being around 30 to 40, which was usually the case with synthetic Menaul type acids, as I recall it ran 16 or very close to 16, indicating about half or maybe a little over half of the inhibition that one would expect in an acid that contained 2.8 parts per million of copper. The analysis showed around 4 parts per million, and that is the analysis that I doubt seriously of the inlet acid, 4 parts per million, much more than we had actually added. The analysis of the exit samples—and we have three of those determinations in duplicate—all showed from 1.2 to 1.4 parts per million. The loss in weight of the tubing that we obtained was 469 grams of iron. From the tests that we had made and have made since then, that loss in iron would agree very closely to the loss that you would get with about 1.3 or 1.4 parts per million of copper. It would not agree with the 4.

The Court: This is the experiment that you and I finally reached the conclusion there were six elements to be considered and two of them must be wrong, and you thought the one most likely wrong was the one that—

(Witness, interposing): —had the least possibility. That is correct. That is the one test that we have dropped after we adopted this 2 series tubing. That is the only one. Now the other tests, in order, and without any great amount of discussion as we have gone over these, run J, or 2B was synthetic; then run K, which was a blank, 2A in our report, followed by L or 1N, which was a no wire test on the first set of tubing—that is the Menaul test without the wire, then followed by N, which was a synthetic on series 2 tubing and is listed as 2D in our report.

Q. Doctor, after you discarded run I, how soon did you run a duplicate of that test? A. We ran it as soon as possible.

Q. Which one was the duplicate? A. It was run J.

Q. The next run. A. Or 2-B was immediately fol-

lowing that, indicating that at that time that we thought there was something wrong, or else we would not have run a duplicate on that.

The Court: How many did you save all told out of all these tests? A. Out of the ones that we have reported without oil,—there are two oil tests,—those have been discarded, and they were not really run under controlled conditions, exactly controlled, because they were preliminary studies.

The Court: Out of the others? A. Out of the others there are 17 tests.

The Court: 16 tests, and 4 of them discarded. A. 4 of them discarded. Two of those discarded were those quick Menaul tests. One was the first test which we didn't have correct cleaning procedure, or other exact analysis procedure, and there were a number of factors wrong there, and then the one, which I will admit is argumentative and debatable is run I.

The Court: It turns out there is just one-fourth of the tests that were discarded? A. That is correct.

The Court: And two oil tests, we aren't counting, that were discarded? A. That is right.

Mr. Owen: Now, Doctor, referring to the copy of your letter of January 28, 1941, to Mr. Rebbeck, in which you made some curves showing the rate of corrosion of the uninhibited 15 per cent acid and of the Menaul acid, that is, from the Menaul tank, can you, or have you the figures from which these crude curves were made? A. Well, following the writing of that letter we ran additional tests, and the data is in this book and could be presented in graphical form, and I don't think I could pick it out of here and calculate it. It would take some little time, and I think it would show up much better in graphical form.

Q. I would like to have you do that, and how long would it take? A. Well, it might take an hour or longer.

Q. I would like to have that done and when done I will offer it in evidence? A. You don't want me to do it right now?

Q. No, wait until you get off the witness stand, and if you possibly can do it so that we can get it in today, so that if counsel wants to cross examine on the basis of it in your notebook you will be here to explain it. Now, you testified that you made tests in accordance with Figure 1 of the Menaul patent and that your results were in general, or generally corresponded with those produced by Mr. Gardner in his affidavit? A. Before we go on to that should I explain those two laboratory tests that we have used for measuring this rate of attack?

Q. Yes. A. I mean that fit in with the picture of these large scale tests, and it is one of those things that I think should be thoroughly understood, and we have mentioned that we used two tests. I mentioned to you at the time of writing this preliminary report that we had used this sample test and run it for a very long period of time, and then the thing after we had run the synthetic run, then we had the problem that the big scale test showed 75 per cent, and the small scale test showed 30 per cent inhibition or so, and to try to find the factors that entered into that we studied the determination in a laboratory way of getting a laboratory test that would duplicate as close as possible the conditions in this large scale equipment.

Now, one thing that we wanted to show with that was that if we took chemically pure acid and added these chemicals to it, that there wasn't some unknown element, X, or something in there that was doing some sort of maneuvering that gave us that large scale result. And further we studied first the surface condition of the samples.

We decided that if we wanted a test that would compare with our large scale test that we ought to use the same method of calculating the samples, and that we shouldn't disturb a great proportion of area of the surface by cutting it with a hack saw, or some method like that, and so we went to a larger specimen and we used a 1-inch length of this 1¼-inch tubing.

We used a 1-inch length of this 1¼-inch tubing. We faced the ends off in a lathe, and got a smooth finish on

the ends, and we finished the inside in the same manner that we finished the large pipe; and the outside we did as close—cleaned it as close as possible to the method used for cleaning the inside. We put it up against a hard wire burnishing wheel which would take the outside coating off, and make a burnished outer surface on the sample.

We pickled the sample before that operation, and washed it with solvent, and then gave it that operation, and then a final washing in solvent as is described in this report.

Then we used the same ratio of acid volume to area of the sample as existed in this large scale test, that is, a certain volume of acid, a certain area of attack, the time was kept the same, the temperature. The only thing that we could not quite reproduce was the agitation, we could not do that in a reproducible manner to let the acid through that small section.

Carrying out the test in that manner, we got results which did not quite agree with the figures that we—when the acid was run through the large tubing system, but it came up pretty close to it, and we thought from work that we had done that increased acid flow gave increased inhibition, or reduction of corrosion; and, therefore, it would be logical to expect possibly that there would be some difference in inhibition.

In this report that I mentioned—I do not recall the PX exhibit number—but the report on the corrosiveness of 15 per cent hydrochloric acid, in that we describe that test, and give the reduction in corrosiveness of various metal contents in C. P. 15 per cent HCl, by that test, and those figures are very comparative, and we used various proportions of copper, lead and iron covering the entire range of any compositions that we had obtained either from our Menaul test, or that had been reported to us by Mr. Rebbeck as having been found in the defendant's samples by Dr. Bartell.

And the figures were 60 to 70 per cent inhibition, close to that range. And we varied the copper. I think I have

described this before. We varied the copper from about two, a little over two to about four parts per million, the lead from around 200 to 500, and the iron from about 400 up to 1300 or 1400, and over that range of compositions the inhibiting action or the reduction in rate of attack was found to be around 60 or 70 per cent.

Now, in our large scale, we got from 65 to 80 per cent, approximately, and we felt that this difference could possibly be explained by the velocity. And then we ran this check of length of time of contact on the samples, and we found that the reduction in rate of corrosiveness was almost constant between about ten minutes and about fifteen hours or so, and it started to fall off at the end of that.

Q. That is the curve you are going to prepare? A. That is the curve I am going to prepare. And the confirmatory nature of that test, with the large scale test, which we duplicated as close as we could in the laboratory, that is, in the small scale laboratory test, indicated to us the validity of our large scale test, and so the two agreed, in our opinion. And so, on the basis of that, the conclusions that were reached, I have expressed already, that the acid containing from 2 to 4 parts per million of copper, and from several hundred parts per million to 500 parts per million of lead, and 500 to 400 to 1300 of iron, in the form of chloride, that that acid, under the conditions of these tests, and apparently from a study of the effect of some of the variables under quite a range of variables and time of contact, gave us an appreciable amount of inhibition or reduction in rate of attack of the acid upon steel oil well tubing.

Q. Now, I have a note here, Doctor, that your preliminary report of March 1st, 1940, in which you report on the first five runs, made no reference to your Run No. B which is one of the discarded runs. A. Yes. That B was never even calculated, because we knew we didn't have sufficient data on the entering acid.

Q. Now, in connection with the Gardner affidavit, you testified that you made some tests following the disclosure

of Figure 1 of the Menaul patent, and that you got low potentials similar to those referred to in the Gardner affidavit. A. We ran such tests in the laboratory, inserting a strip of steel and a strip of lead into hydrochloric acid of various concentrations contained in a beaker, similar to the sketch shown in the Menaul patent, and determined with a potentiometer the potential difference between the two strips of metal.

Q. And that compared favorably with Gardner? A. I would consider it a favorable comparison. I think we had quite a discussion about some differences there, but I think they are in substantial agreement.

Q. I want you to state whether the results of your—of those tests which you made in any way alters the views you have expressed regarding the effectiveness of the Menaul method in giving protection to the well tubing? A. It does not alter one particle the conclusion that I gave you or my opinion on that matter.

Q. The fact has been brought out in cross-examination that in your Menaul tests you grounded the lower end of the tubing instead of the upper end of the tubing, which would ordinarily be grounded in an oil well. How would the change in the point of grounding affect the amount of current passing down the tubing? A. Why, I have testified that the grounding of the tubing at any point along the tubing would be substantially identical because the tubing is a very high—has a very high conductivity, and it was brought out in cross-examination, I believe, that this tube was grounded through contact with the casing at the top, and which would indicate a difference between what we have carried out in our test and what occurs in a well. I do not believe that makes any difference.

Then it was brought out that possibly the current we measured was not all the current that passed in that circuit, that some of it may have gone into the ground, and the connecting of the ground to the bottom of the tubing would tend to make it easier for such a current to pass down and protect the tubing, and if there were going to be

any protection, why, it would be protected better along the tube and down to the bottom end by such a connection.

Q. Where did you measure the potential in your tests made in accordance with Menaul's figure 1? A. The potentials were measured directly between the side of the tank and the tubing, the end of the tubing system, which was dipped into the acid.

Q. And where did you measure your potentials in the Menaul tests? A. That is what I just described to you, in the Menaul tests I measured between the tank and the tubing.

Q. Oh, yes. I wish you would compare the potentials you found in your tests, corresponding to Figure 1 of the Menaul patent, and those you found in your tests using the 110 feet of pipe. A. I believe that I went into quite a thorough discussion of the voltages that I measured between the strip of lead and the strip of steel in this little beaker, and they were around one-tenth of a volt, if you recall. Gardner got eight one hundredths, and I got thirteen one hundredths as the top figure, and in between we criss-crossed, but they were substantially a tenth of a volt.

On cross-examination I was asked as to the exact number of these potentials, and I got down a certain way in reading voltages before I was stopped, or interrupted, or something. In run 1-M, the voltage that occurred between the tank and the tubing at the start of the run, when the tank had 40 inches of acid above the lead sheet in it, was 0.00 volts.

The Court: Above the bottom of the lead sheet? A. 40 inches above the top of the lead sheet, which we measured.

The Court: Oh, the top of the lead sheet? A. Yes. It was 0 volts. Then when there was only 34⅛ inches of acid left in the tank, the voltage was .0012 volts. When there were 26½ inches of acid left in the tank, there were .0018 volts. Then when the acid was 22 5/8 inches deep, about half of it had gone through then, there were .0039 volts. Then when the acid was 18 5/8 inches, when there was that much acid left in the tank, it was .0043 volts.

Then when there was 15⅛ inches of acid left in the tank, there were .0081 volts. When there were 11⅛ inches of the acid in the tank, the voltage was .0174. When there were 7 inches of acid in the tank, the value was .030 volts. When there were 3¼ inches left in the tank, the value was .064 volts.

Now, I have four runs, and they all show potentials and voltages of about that same order of magnitude; the voltage was practically zero, and as the acid ran down in the tank, the voltage started up toward the values that we got in the beakers, they started up towards those values. But it did not occur until there was just a layer of acid covering the lead sheet. Now, one of the principles of the Menaul hypothesis in the plating of this tube is that a large flow of current occurs and coats over this tubing to flow into the tubing and give it this polarization, and these figures clearly indicate that nothing like that occurs in the beginning.

Now, the voltage you get at the end is due to the fact that when you take a composite electrode, and an electrode that is four-fifths steel and one-fifth lead, and you measure the potential between that electrode and another electrode, you get sort of average voltage of lead and iron between what other electrodes you are measuring, and therefore since the acid in the tank is in contact largely with steel in the beginning, you get a voltage of steel to steel, which is substantially zero, and then toward the end when the acid has fallen down and is in contact with almost 99.5 per cent of lead surface, then the potential of that element is about the same as a sheet of pure lead measured against iron, which we found to be one-tenth of a volt in our beaker tests, but that still,—the explanation that I have given, or the opinion that I have given on the impossibility of this few hundredths of a volt, even in the last few inches of acid, in the test, of doing any protecting, the possibilities of that are—I do not believe exist, and these voltages, the change in voltages is exactly what you would expect and you cannot on the basis of those potentials give any credence to

the idea that there was a polarization due to a flow of current, and then the current stops and you have everything held free from corrosion.

RECROSS EXAMINATION

By Mr. Lyon:

Q. I have a few questions. Did you make any tests to determine the amount of copper and lead or iron that would be picked up by the acid if you put it in the Menaul tank, or the rate of corrosion in that tank of the acid if the plate was not bonded to the steel wall? A. No, we did not. We did make some preliminary calculations. We found so much corrosion there that we just wondered. We thought, and I still think that the lead sheet does protect the tank somewhat, and we tried to make some rough calculations that would indicate that it might protect it 30 or 40 per cent, but that could hardly be exactly. We have nothing to compare it with.

Q. You referred to that as a little bit or a slight amount the other day. What amount of protection did you have in mind? A. Well, I don't know from electrolytic protection. In these rough calculations we figured 30 or 40% electrolytic and then there is some chemical inhibition. Just what the total might be, it might be fairly high. We found a considerable amount of iron dissolved much more than the field samples showed. We had four times as much iron in our solution at the end of six hours with mild agitation as Rebbeck reported to me as being found in the field samples.

Q. Did you make any tests attempting to find out what the results would be if you could get a lead plate that contained no copper and were able to entirely exclude copper from the system? A. No, we did not.

Q. Would you have any idea as to what the results would be if the defendant's system, the Menaul system was operated just the way it was and by some means you were able to keep the copper out of the solution? A. I couldn't tell you that without running tests, I don't believe.

Q. You didn't run any? A. No, we did not run any tests whatsoever on that.

Q. This brush that you used as a burnishing brush for the tubing between tests, what was it made of? A. It was a hardened steel wire brush. Mr. Lightfoot, could you describe it better? What were the wires? They were round wires, cross section, and about how long? Was there any copper or anything on that brush?

Mr. Lightfoot: It is a brush commonly used for cleaning flues.

Q. That brush would scatch the inside of the tubing more or less, abrade the tubing. A. Somewhat.

Q. Isn't that known to affect the rate of corrosion of a metal if you abrade it or scratch it? A. Yes.

Q. It changes the rate.

The Court: Because you increase the surface. That is the main reason. A. That is one reason. If you work metal it tends to corrode a little more than if you do not.

Q. Have you read this current article appearing in the August, 1941, edition of Industrial and Engineering Chemistry entitled "Causes of Corrosion Currents" written by R. B. Mears and R. H. Brown of the Aluminum Company of America? A. I have been too busy sitting here in the courtroom to read any articles.

Q. You know this publication? A. Yes, sir.

Q. Did you ever hear of either Mr. Mears or Mr. Brown? A. I am very sure I have.

Q. Are they competent men in this field? A. As I recall they are. Mr. Mears, I am quite sure I have seen his name.

Q. There is a summary apparently of this article at the top, as I guess they have in these various scientific articles, in larger bold face type, and I am going to read to you and ask you if it is in accord with your experience—"Localized attack of metal specimens is often the result of electrochemical corrosion, not of simple chemical solution. The appearance of specimens suffering this type of attack has led laymen to attribute it to the presence of impurities

in the corroding metal. However, impurities are only one possible cause for this type of attack. Other known or possible causes are: (1) grain boundaries, (2) orientation of grains, (3) differential grain size, (4) differential thermal treatment, (5) surface roughness, (6) local scratches or abrasions, (7) difference in shape, (8) differential strain, (9) differential pre-exposure to air or oxygen, (10) differential concentration or composition of the corroding solution, (11) differential aeration, (12) differential heating, (13) differential illumination, (14) differential agitation, (15) contact with dissimilar metals, (16) externally applied potentials, and (17) complex cells. In cases encountered in practice, 4, 6, 10 and 11 appear to determine the local sites of attack more frequently than do any of the others.

"The magnitudes of potential differences generated by several of the causes listed have been determined experimentally and are given in the paper. In several cases examples illustrating the special attack resulting from these causes are described." A. What do you want me to say?

Q. That is a list of the different factors that can affect the corrosion? A. Sounds like a very complete list and the degree to which they affect corrosion, of course, varies from case to case. Was your question directed to the mechanical working?

Q. No, I was asking if this was in accord with your experience; these are the factors that affect corrosion. A. Yes.

The Court: He has left out of there the different kind of thing—whether it be air or fluid contact. A. This is all water solutions they are talking about. He mentioned the condition of the solution.

The Court: There are seventeen different kinds of things, then, that you agree affect the percentage of corrosiveness or inhibition of anything?

Mr. Lyon: The rate of corrosion, I would put it. To digress for a minute. If you are not familiar with it, I would like you to look at his data here. You may have already experienced it. He shows a difference in illumina-

tion of the same surfaces; one being lighted and the other not, would make a difference. A. I think it was kind of dark inside of those tubes.

Q. Well, is that your experience? A. I have no experience with that, and the tubes were dark inside, and the bottles that we had in our thermostat for the lab tests were only a small percentage of the surface area—I mean, only a small percentage of the surface area was exposed to the light. I don't believe that that would account for much. I think you asked me a question about the surface working on metal.

Q. I did, and I thought you answered it. A. All I wanted to say on that was that this wire brush did not disturb a great portion of the depth of the surface, and that is shown in this time of contact of the acid on the oil well tubing. The curve I am going to present tomorrow gives at the start—the rate is very fast, and it is taking off that loose metal and the working metal. The work metal will usually dissolve much faster than the annealed metal, and that occurs in the first few minutes. That is where your 17.8 per cent came from, and that is one of the reasons of running it a greater length of time, because that gives you a more reproducible and more representative value on the reduction of corrosion rate.

Q. Of course, there would be no possible way that the man running this boiler job cleaner through those tubes back and forth could be sure that he had the same abrasions, and the same amount of working on the inside of the tube in one operation, as compared with another; he would just have to take a chance on that and do the best he could?

The Court: Maybe you could make some tests and tell whether the brush took out the dandruff, or whether it just scratched the scalp. A. We did. We didn't make tests, but we just measured what came out, and there was a little black material, which was probably impurities and particles on the surface, but that was all that came out, there was no steel.

The Court: The thing I have got a picture of is that brush is a pretty harsh brush, I wouldn't want to brush my hair with it. I just wondered that if you kept on using it there, if you would not keep on getting little particles of iron out. A. You would get some, but it was only brushed through once and pulled back once.

The Court: Every time it goes through then it probably digs a little bit of iron. What is loose will come out easier. A. Yes.

The Court: You take those are almost at right angles, except to the extent you bend them to that wire? A. That is correct.

The Court: I suppose they would tend to abrade? A. And I am perfectly willing to admit that.

The Court: The extent of it I haven't any idea, but I would think it would abrade some. You never did make a test by weighing that iron pipe before and after. A. In the corrosion tests?

The Court: Yes. A. We have those figures and they agree quite closely with the figures in the analysis.

The Court: In that sort of test when did you weigh your pipe? A. After I cleaned it. The figures in general are higher. We took only, took out a few grams with that brushing out operation. It was really the start of another test.

REDIRECT EXAMINATION

By Mr. Owen: Q. I want to ask the doctor if these charts which have been produced correctly represent the data contained in his reports PX-184 and 185? A. They do.

Q. And I will ask you further, did you check the figures on those charts after they were submitted to you by Mr. Rebbeck, after drafts of them were submitted to you by Mr. Rebbeck in connection with his letter of July 11, 1941, Defendant's Exhibit No. 227? A. The figures agree. The results are the same. When we wrote up our

preliminary reports we did not want to use any per cent reduction in corrosiveness. We simply wanted to indicate a rate of metal dissolving, and with raw acid, and report the rate of metal dissolving with the acids that we found in the various tests. And that was one of the main points that was mentioned in some of these talks and letters was that the attorneys had decided, well, we are going to do this way, and then Mr. Rebbeck agreed to re-calculate the results and make up a chart which I could check, based on the method of presenting the results.

The Court: Doctor, what would be a definition of inhibition? A. The word "inhibition"?

The Court: As applied to chemistry. A. Not per cent inhibition?

The Court: No. I am intentionally leaving that out. Or I will say an inhibitor. Perhaps that would be a little easier. What would you say a chemical inhibitor was? A. An inhibitor is a substance which is usually put into a corroding medium in small amount and which reduces the corrosive tendency of the medium.

The Court: Well, now, you have just testified to using something that inhibited, because inhibited is the reverse of corroded, and when you tell me it stops corrosion you have just used— A. (Interposing): That is true. It is a vague term, but that is my conception.

The Court: Well, Webster says that it is something that prevents reaction. A. That is probably more exact than my statement.

The Court: Well, I am wondering now, is Webster right, and that I have led you into a good definition by quoting Webster? As to what prevents it, is it the coating or the plating that goes on? I have trouble when I read "inhibition" to try to apply it to the results I have got. A. There was some discussion as to whether the material had pulled the teeth out, I think the term was used, of the acid.

The Court: Yes. Webster seems to speak of it, he doesn't say that, of course, but you think, to read the definition, that there was a reaction took place in the corrosive

substance, that the reaction took place, that prevented it from corroding by a reaction taking place. Now, that is rather contrary to the plating idea, isn't it? A. Well, there are different types of inhibitors.

The Court: Of course, he doesn't say anything about hydrochloric and he doesn't say anything about arsenic or any of these inhibitors we have talked about, and I take it that it is a term that applies to many things other than hydrochloric acid and steel. A. Yes, very many. Oxidation, lubricating oils.

Mr. Owen: I have here the chemical engineering dictionary, which contains a good definition of inhibitor. (Reading): "Any substance which slows down or prevents chemical reaction or corrosion." Very much like Webster.

The Court: He didn't put the "corrosion" in.

Mr. Owen: Webster did not.

The Court: This is better. Webster just had the broad idea.

Mr. Owen: Just one further point that my associates are a little bit disturbed about, and that is the statement that I was responsible for Dr. Prutton's reports, and they are very anxious to have me read these letters which were offered, but I don't necessarily want to do that, if—

The Court: I will say this on the record, that I think in most courts they would never have found out about that, and I think that what has been done is usually done; they talk together, and they work together. Of course, you have the natural prejudice that anybody has, trying to honestly represent the people he is working for; and it is easier for you to see your side, and the others to see their side, than perhaps it is for me to see either of your sides. I can see that that enters into it. I am not feeling cross towards anybody, or thinking ill of anybody. If that is what you have got in mind, you don't need to spend any time on that.

Mr. Conner: Mr. Lyon had said, he was having you (Mr. Owen) telling Prutton what to report.

The Court: Most judges don't get into all that sort of thing, but I do, and it is helpful to me. I think it is a good thing to do myself.

Mr. Owen: That is all, then, Your Honor.

The Court: You see what I am doing, I am putting my own approval on what I have done.

Mr. Owen: That is all I have, Doctor.

The Court: I am putting my own probe in.

Mr. Owen: I wasn't disturbed about it, but my associates were.

The Court: I say feel perfectly free to put in anything you want, but I am not surprised at what I found out at all, and I am going to be surprised if I don't find that the others have made some experiments that they think they made a mistake in.

Mr. Owen: I hope that their insides will be turned out as thoroughly as ours have been.

The Court: I will try just as hard to do it.

Mr. Owen: Dr. Prutton has made that sketch I requested. I would like to have him explain it. I will give it exhibit number PX-234.

(Whereupon the sketch was marked PX-234.)

Dr. Prutton: Now this chart was prepared from data that was obtained when samples of this 1¼" oil well tubing 1" long were tested for the amount of corrosion in this standard laboratory test that we employed which gave results comparable, as we felt, with the large scale results. We tested the rate of corrosion using different lengths of time of immersion of the specimens in the acid. If we plot vertically over here (witness drawing on blackboard) the rate of corrosion or the grams or iron dissolved per square meter of surface per hour of contact, those numbers are plotted vertically, and horizontally we plot the time of test or time of contact in hours, and we start here with 2 hours, 4, 6, 8, 10, 12, going out to 16 hours; and here (indicating) we plot, let's take a maximum of 125 grams, 100, 75, 50 and 25.

The first tests were made upon 15% chemically pure hydrochloric acid and the time of test was 3 minutes. The rate at which the iron dissolved, figuring from the weight loss from the specimen and area surface exposed, time, the

rate was for 3 minutes which was practically over here and against the axis was 107 grams of iron dissolved per square meter of surface per hour of contact. That is simply the rate at which the iron was dissolving over this 3-minute period (indicating on the blackboard). Then the next test was run, using a section of oil well tubing in 15 per cent C. P. hydrochloric acid, and 6 minutes was employed. Now, at 6 minutes, the average rate of solution of the iron was 82.2. The next test was run for 12 minutes, still over in close here (indicating), and was 77.8. You see, this was 82.2, and this is 77.8, at 12 minutes. The next test, and these are entirely separate tests that were run in duplicate, this is a 30-minute test, which would be a half hour, and this is 76. In other words, the rate of dissolving of the iron by the acid was very rapid here, and then in a few minutes it came down to practically a constant rate. Now, 3 hours, in the 3-hour test the rate was 72½. 6 hours, 71.8. At 9 hours it was 70. I will put the numbers opposite each point. In 16 hours, the rate is—I have it indicated on the graph here, but I do not have it numbered. It is about 60, out here (indicating), plus or minus 2. That is just from the graph, which I took from the data. I don't recall the number. Now, this curve for C. P. hydrochloric acid shows—

The Court: That is almost a tangent, after it reaches 3 hours? A. 12 minutes (indicating). This is 12 minutes. This is 6 minutes here (indicating), and this is 12 minutes here, and then 30 minutes. Now, if we take an acid containing copper, lead and iron in a concentration of—this particular acid happened to be three parts per million of copper, and a thousand parts of lead, just a little higher in lead. Then the defendant's acid, or the acid that we obtained from the Menaul tanks that we employed, for a laboratory test, gives us the same rate substantially at the 3-hour test—in the 3-hour test with this acid containing lead, copper and iron, 3 minutes gave 80 grams per square meter dissolved. Six minutes gave 69.8. And 12 minutes 40.4. And 30 minutes 34.8. And 180 minutes 22.2. And

360 minutes 17.6. Now, 540 minutes, or 9 hours, 18.4, which is a little higher but substantially the same. Now, if you draw a curve through these points as well as you can, with this acid containing copper, lead and iron, you get a curve of that type (indicating). The difference between the height of this line and the height of that line (indicating) is what we have been talking about as this percentage inhibition, if you express it in percentage of the total height, or if you just take the difference here you would have a reduction in the rate of corrosion. For example, if we have an iron tubing in 15 per cent C. P. acid and we run a test for three hours, we get a rate of 72.5 grams of iron dissolved per square meter per hour. If we run it with this lead, iron and copper containing acid, 22.2. Now, these figures are quite representative of and are within one or two units, this of the crock acid that was used in our tests, in all the tests we ran on the crock acid, and this of the Menaul or synthetic acid. In other words, within two or three down here and two or three up here (indicating).

Mr. Owen: That upper line, Doctor, you said all the tests you ran? You mean all? A. These were run with C. P. acid.

Q. Without any additions? A. Without any additions whatsoever. Now, our actual crock acids were a little lower than that. We ran a curve for those, but they were somewhat lower in the three hour test, but here we have this C. P. and the difference between the two is the inhibition. Now, in a letter that I wrote to Mr. Rebbeck I gave him some preliminary numbers for this difference up here, or three minutes test, which showed about 18 or 20 per cent inhibition. At three minutes this height is 20 per cent of the total height, and that, as I explained, I am quite sure is due to the loose iron that is on the surface being attacked at a more rapid rate right at the beginning, to loosen that up. You see, there seems to be lost practically no weight. All this loss of 107 grams per square meter per hour, you only have it on one-twentieth of an hour, and the amount dissolved is that loose fuzz on the surface.

When you get down here to a ...ing over twelve minutes you are getting down to wh...e drop in corrosion due to the addition of these metal... educes the corrosion about fifty per cent, that is, the ...rosiveness or rate of corrosion of acid containing copper, lead and iron is about half of the total height of the corrosiveness of the C. P. acid. When you get over here it is 60 to 70 per cent, but between 12 minutes and out here as far as we went the difference here is not tremendous.

Now, that was the figure that was cited out of this letter that was written and the reasons for the running of this curve was in explanation of what we felt was happening in the rate of corrosion samples.

RECROSS EXAMINATION

By Mr. Lyon: Q. In accordance with what you have just illustrated on the blackboard and with this curve you have produced the per cent of reduction in corrosion as illustrated on the chart such as PX-189 or the one in front of you, which is one of the corresponding charts would be different for each difference in time, isn't that correct? A. At any time between 12 minutes and about 7 or 8 or 9 hours out here, if we measured the difference might be 10 or 15 per cent.

Q. As against what? A. As against,—that is, 50 compared to 65 or something like that,—55 compared to 70.

Q. Now, I want to ask you as follows, and you can take this down if you want to, in taking the figures you have put on the blackboard, the per cent of reduction in corrosion in the system that you have illustrated there for three minutes would be 25.4; 6 minutes, 15.0; 12 minutes, 48.0; 30 minutes, 54.0; 3 hours, 69.4; 6 hours, 75.5, and 9 hours, 73.7. If those are not correct, it will just take you a minute to check them and I wish you would give us the actual differences in per cent, using the method of calculation that were used in these charts, such as PX-189 for the 3 minutes, 6 minutes, 12 minutes, 30 minutes, 3 hours, 6

hours, and 9 hours. A. Well, do you want the exact figures, or a general statement? You don't want any exact figure?

Q. Just substantially. A. Those are substantially right, I would say.

Q. The ones that we gave you? A. Yes.

Q. We calculated them in a hurry. A. They are close. In other words, here is—substantially they are right. I would say, just looking at them, I would say they are substantially correct.

Mr. Owen: There is one other point I want to cover. Your Honor will recall that back in the beginning of this case we introduced as PX-10 a chart with some parallel streams and a delta at the bottom, showing the results of the Grebe-Sanford patent, and how it has grown in a few years.

The Court: Yes.

Mr. Owen: And we were criticized, or the witness Mr. Penhaligan was criticized on cross examination because he had included in those figures certain treatments that were made for mud removal in the California field and some for stuck drill pipes, and Mr. Penhaligan, who is not a chemist and is the auditor there, in making up his figures included all of those because they went through his books as business for Dowell X. In view of the criticism we had Mr. Penhaligan go through his books again and take out all those California treatments and all the stuck drill treatments and things of that kind, and I would like to get this in by submitting it to counsel and avoid recalling Mr. Penhaligan, if that is possible.

The Court: Submit it to them and let them look at it.

Mr. Owen: Then Mr. Penhaligan has also made up a list of treatments made by licensees other than Dowell, which I would like to offer, and those are made up by months, beginning with the year 1934, and ending with the year 1940.

The Court: Have those marked right now and offer them and then I will wait and see what they say about it later on.

Mr. Owen: I will have the sheet showing the deductions from the figures shown on our chart PX-10 marked PX-232, and the sheet showing treatments made by licensees of Dow, other than Dowell, will be marked PX-233.

(The sheets were thereupon marked PX-232 and PX-233.)

Mr. Owen: We will hand these to defendant's counsel for study.

Mr. Owen: A couple of days ago we had identified as PX-232 and 233 two sets of data prepared by Mr. Penhaligan the first of which shows the figures of total treatments, which are included in PX-94; that is, the total treatments made by Dow and Dowell, and the question was asked whether it included certain mud treatments in California, and treatments for the removal of stuck drills, and I had Mr. Penhaligan recheck it and deduct treatments which related to the removal of stuck drills and the California treatments, and the corrected figures are given down at the bottom, opposite the words "Net total." I want to know whether defendant will stipulate that Mr. Penhaligan would testify to the correctness of these figures if recalled.

Mr. Lyon: If I understand it, on Exhibit 232 the individual jobs deducted from the previous figures which were on PX-94 represent jobs where the acidizing was not to increase the production?

Mr. Owen: That is right.

The Court: These are actual figures?

Mr. Owen: These are actual figures taken from our records.

Mr. Lyon: I am willing to agree that he would testify to these figures of these deductions if brought in, but in connection with that I would like to offer these two advertisements of the Dowell Company in connection with the importance and the character of the operations which were formerly included in Exhibit 94, and which now will be deducted from Exhibit 94.

Mr. Owen: I don't have any objection to that.

Mr. Lyon: The first one is entitled "Out In Front." It appeared in the Petroleum World for September, 1938, and it is entitled "Out In Front," and has an explanation, "Out in front with lime scale removal.

"Removal of lime scale is among the important specialized services Dowell has perfected expressly for California producers.

"Lime (calcium carbonate) scale presents a special problem well worth solving, as these deposits, led by water, block off producing formations and production declines abnormally.

"Dowell, after long study and practical field work, has perfected a special service that leaves nothing to guesswork. Dowell uses inhibited acid which protects metal liners, while rapidly dissolving calcium carbonate."

And I want the court to bear this in mind in connection with this, what the Gypsy did, which was read in evidence, down in Oklahoma, where they were doing exactly this, and Dowell is advertising this.

(The advertisement above referred to was thereupon marked Defendant's Exhibit No. 242.)

Mr. Lyon: I will now produce and ask to be marked as DX-243 a page advertisement of the Dow Chemical Company in the Petroleum World for January, 1939, the advertisement reading:

"Dowell scale removal treatment.

"For California producers.

"Dowell Chemical removal of carbonate scale increases profits.

"As indicated so graphically in the chart reproduced above, actual results obtained in numerous Dowell treatments for carbonate scale removal demonstrate the great value of this special service for California producers. It is a service that is proving itself, again and again, an exceedingly profitable investment for the operator.

"Dowell carbonate scale treatment and technique of

application have been carefully developed and perfected to meet conditions as found in California wells.

"Inhibited acid, to which a wetting agent is usually added, is pumped through the casing head into the annular space between the tubing and casing. The acid comes in contact with the scale both on the outside of the tubing and, still more important, on the perforated section of casing or liner.

"Treatments and technique of application vary according to conditions as tested and determined by Dowell technicians. And case histories tell the same story—restored production and increased profits."

We offer that, which on its face is obviously the same treatment that the Gypsy was using.

The Court: Except the inhibitor.

Mr. Lyon: Well, the Gypsy had the inhibitor in. You remember Dr. Wescott of the Mellon Institute recommended the inhibitor.

The Court: Yes.

Mr. Lyon: And they put the inhibitor in down in Oklahoma.

(The advertisement above referred to was thereupon marked Defendant's Exhibit No. 243.)

Mr. Owen: If Your Honor please, PX-233 is a statement prepared by Mr. Penhaligen, showing the number of treatments made by licensees of Dow under these patents, other than the Dowell Company, and that shows a total of 2277 treatments, and does not include treatments made by California licensees.

Mr. Lyon: I would agree that your witness would testify in accordance with this Exhibit PX-233, but in accordance with Exhibit 232, these deductions that have been made from Exhibit 94, am I correct, Mr. Owen, that you have deducted from Exhibit 94, in this Exhibit 232, the scale treatments, or the jobs that have been done in accordance with these last two advertisements that I have produced here; or are they still included in these figures that remain after the deductions appearing on Exhibit 232?

Mr. Owen: It is my understanding that they are excluded, but I will have that checked.

Mr. Lyon: Would you have that checked because I would like to know whether the figures that are presented here under the patent in suit include these lime scale removal jobs, or not. For obvious reasons, I think the court should know that.

The Court: He will produce that, and I will admit 232 and 233.

Mr. Owen: Now, in connection with depositions taken in this case in Duncan, Oklahoma, Mr. Clason produced a number of acidizing tickets which were marked in that deposition PX-7 and numbered from 1 to 113, there being a total of 113 tickets.

I wish to offer those tickets as an entirety here as PX-244.

(The defendant's acidizing tickets referred to were thereupon marked PX-244.)

Mr. Owen: Then I wish to call upon defendant to produce the orders relating to these particular jobs covered by these 113 tickets. The orders, I will say, contain information that is not contained on the tickets, and that is the reason I am asking for them.

Mr. Lyon: We haven't got them here. It would require a considerable work to go back through the records of the company and dig out all the orders which these tickets correspond to. The tickets were produced when they asked for them. They have never asked, as far as I know, for the orders, and I don't see how we can have them here now in time, and I don't think we should be asked to go get them. I don't understand the orders have any information on that the tickets haven't got. What could be the information you want? Maybe we can cover it in some other way.

The Court: These are orders from the customers?

Mr. Lyon: Yes; but these are the actual operations. I don't see where all these jobs come in on this case in any special way in this hearing. They are all the jobs ever done

in Michigan up to the filing of this complaint, and I can't see that those individual jobs are involved unless we come into an accounting, and what is the information you want off the orders? We want the court to have any information that the court wants, but to go find 113 orders through our books back four or five years ago, is a job. They don't really need them. What is it you want to prove by it? Maybe we can make some statement that we could prove—

Mr. Owen (interposing): We want to prove the depth of these wells and the length of the casing, the distance from the bottom of the casing to the bottom of the well, and the length of the tubing.

Mr. Lyon: Well, aren't you willing to accept the four wells which you took your samples from here as typical of what the defendant was doing here in this district?

Mr. Owen: Yes.

Mr. Lyon: You have that data for those four wells.

Mr. Owen: We have that, yes, for those four wells, and I can't answer that because I don't know whether it would be typical, but I will consider it, and in the meantime I would like to have you endeavor to get that information from your home office.

Mr. Lyon: We can't get it here. It would take considerable time. I am not sure how long. Probably a couple of weeks, to go through all the records. This stuff is all permanently separated in the files of the company, by oil companies. Now, these oil companies, for instance, like the Ohio Oil Company operates in many places in the United States. We would have to check through all of their orders to pick out those that came and were filed under their name from Michigan, and then they would have to be sent up here.

Mr. Owen: I am sorry you didn't understand my request. I thought I made it perfectly plain. I introduced photostatic copies of just what you have produced here today, and I requested at the same time that you produce these agreements.

Mr. Lyon: Well, I understood, Your Honor, that this

case was being tried on the basis that the four wells that the specific samples were offered from were typical of what they alleged was an infringement. Now, they have the data on those four wells.

The Court: Can't we get that, Mr. Owen, and see what that does show with reference to those four? Does that show you what you wanted to prove?

Mr. Owen: As to those.

The Court: If it does, for one well, and you agree that is typical of the others—

Mr. Owen (interposing): As to those four wells, it does show the information, and we will consider that this evening.

The Court: Was favorable to you.

Mr. Owen: I don't know whether it is favorable or unfavorable. All I want—

The Court: But I guessed the point to it, you want to show the acid would come in contact with the iron?

Mr. Owen: Right.

The Court: That is what you want?

Mr. Owen: Right.

The Court: Does it in those wells?

Mr. Owen: I think it does.

The Court: Well, then, say it is typical of the others, then you have shown you come in contact with all those wells, I take it?

Mr. Lyon: He means by "coming in contact," he wants to know how long it takes it to go down the pipe.

Mr. Owen: How long it is in contact?

Mr. Lyon: With the pipe going down.

Mr. Owen: The length of the tubing has something—

The Court: On that now he says he is willing to take those four as typical of how long they take, and those are the four—they did not make them out, I don't reach the conclusion that they have selected those that will show the best for them.

Mr. Owen: Your Honor, I have some figures here that have been gotten up from the books and records of the Dow

and the Dowell companies, regarding their advertising expenditures during 1932, 1933 and 1934, and also as to the amount of business transacted in this acidizing business during those years. I would like to read them in the record, with the understanding—

Mr. Lyon: I have not seen them before, and I do not know what they are.

Mr. Owen: I will defer that then with the understanding that I may put it in later. I will get a witness here who will prove it.

The Court: You can put it in later then.

Mr. Owen: Yes, I can put it in as part of my rebuttal.

The Court: Yes, or at any time I will interrupt the other side long enough for you to put it in, if you want to. I will make it that convenient for your witness. While I like to have a plaintiff, when they are putting in their proof, put in all they have got in mind, and the defendant all they have in mind, why, if something is overlooked, I want them to put it in later, if they discover that something has been overlooked. I don't want you, for instance, in announcing that you have rested here to be uneasy for fear that you have forgotten something. Any time before the final decree will be time enough.

Mr. Owen: Yes, Your Honor. The next thing I have is a printed price list, or, it is called service price schedule 110 of Dowell, Inc., which became effective June 23, 1937, and I am offering it for the purpose of showing that the blanket service, the jelly seal service and the surface tension reducing agent were not charged for within certain limits. For instance, the Dowell X is inhibited hydrochloric acid solution. Dowell XF is Dowell X, with the surface tension reducing properties for use in low pressure wells; and the charge item No. 4—no, item No. 1, is 500 gallons or less Dowell X or XF service. Then it gives the price of the treatment. There are three different classes here, evidently for different locations, and that is all on the price list, so I won't read it.

(The price list referred to was thereupon offered as PX-245.)

Mr. Owen: Now, the only other exhibits I want to offer in connection with my prima facie are two sets of tables that Dr. Bartell furnished to Mr. Lyon, at his request, and I would like to offer this set in connection with the copy of Dr. Bartell's letter to Mr. Lyon dated August 4th, which states:

"Acting upon your request I am sending you herewith the experimental data which was obtained in our acid corrosion tests with samples numbered 1 and 2 from the Stella Wilcox Well." I will offer that carbon copy of the letter and the four sheets of data as PX-247.

(The document above referred to was marked PX-247.)

Mr. Owen: I offer as PX-248 carbon copy of the letter written by Dr. Bartell to Mr. Lyon August 4th, reading as follows:

"Acting upon your request I am sending you herewith the experimental data which was obtained in our acid corrosion tests as presented in and described in our Table XIX (PX-167)," and attached to that copy are 3 sheets of data.

(The document above referred to was marked PX-248.)

Mr. Owen: That closes my prima facie case, Your Honor, with that reservation I made, which you granted.

DEFENSE PROOFS

DON HATHORN,

a witness called by defendant, testified as follows:

I am an engineer in the employ of the defendant, Halliburton Oil Well Cementing Company and live at Duncan, Oklahoma. I have been for some time in the Patent Department of that company, assist the Patent Department in making tests and tabulating data. I have conducted certain tests for this case with reference to the operation of the Menaul method of protecting the tanks employed by the defendant in acidizing oil wells. Assisting me in these tests I had Menaul in at different times, and I had four different assistants from Halliburton laboratory, working under my supervision. They were Frances Anderson, George Mirham, Bill Barrett and Zema Ballinger. The work they did was done under my supervision and recorded under my supervision. All of this work—that was done by my assistants and by me personally—was recorded at the time it was done in certain books of original entry. I have those books here and will produce them.

(Witness produces books.)

Everything is recorded in this, but some titration numbers are in here (indicating another book), but they are transferred to this book (indicating).

Mr. Lyon: The book which the witness has just identified is offered as DX-277.

(The book referred to was thereupon marked DX-277.)

I might say that there are some other data in there which do not relate to this lawsuit (indicating) but all of the actual determinations made in the tests on the Menaul tank conducted by me, or under my supervision, are entered in this Exhibit DX-277. This is the book of original entry of those tests.

(The second book referred to was thereupon marked DX-278.)

This book was used in recording some of the titrations, but being as this other book was in use on other experiments that were going on at the time, they were recorded in this second book, and then transferred to the first book. By titrations I mean the chemical tests as distinguished from the weighings and readings which are in 277. These titrations were recorded in 278 as the book of original entry, and then they were transferred to 277. I have taken the readings and titrations recorded on Exhibits 277 and 278, and plotted the results of the various experiments in the form of curves, and in doing so I made certain calculations. I have the book in which I made the calculations (producing a book).

Mr. Lyon: I will ask that this book be received and marked DX-279.

(The book referred to was thereupon marked DX-279.)

Mr. Lyon: I will ask that the first one of these curves, entitled "Hard steel tank No. 1," be marked DX-280.

(The curve referred to was thereupon marked DX-280.)

Mr. Lyon: That is the first sheet. The various sheets are all attached together. The second sheet is marked "Hard steel tank No. 2." I will ask that that be marked DX-281. The next sheet is marked "Hard steel tank No. 3." I will ask that it be marked DX-282. The next sheet is marked "Soft steel tank No. 4. Sheet 4." I will ask that it be marked DX-283. The next sheet is marked "Soft steel tank No. 5. Sheet 5." I will ask that that be marked DX-284. The next sheet is entitled "Hard steel tank No. 1. Sheet 6." I will ask that that be marked DX-285. The next sheet is entitled "Soft steel tank No. 4. Sheet 7." I will ask that that be marked DX-286.

(The sheets referred to were thereupon marked DX-281 to DX-286.)

These various curves that appear on Exhibits DX-280 to 286, respectively, were drawn by me from the data observed in the experiments recorded in Exhibits DX-277,

278, with the calculations in Exhibit 279, and to the best of my ability they correctly set forth graphically the results of the experiments recorded in those exhibits. I have an index prepared which will enable anyone interested to readily find in Exhibits 277, 278 and 279 the various values which are plotted on the curves, Exhibits 280 to 286 (producing document). It is entitled "Index for corrosion experiments."

Mr. Lyon: I will ask that that be marked DX-287.

(The index referred to was thereupon marked DX-287.)

Mr. Lyon: Will you take these different sheets, identify them by exhibit number, and tell us what the experiments were, briefly, the results of which are plotted in the individual curves appearing on the sheets, because, as noted, each one of the curves on each sheet is numbered so that they can be found on the index? First, Exhibit 280, curve No. 1; what is that curve? A. It is a curve of commercial acid placed in an iron tank, steel tank, which is made of the same material as the defendant's truck tank, and the solution of hydrochloric acid was agitated and samples taken at each one of these points along the curve and the test continued for about 42 hours. I have the tank that was used in that test. The tanks are over here (indicating). This (indicating) is hard steel tank No. 1.

Mr. Lyon: I will ask that that be marked DX-288.

(The tank referred to was thereupon marked DX-288.)

The other tank is what we call "Soft steel tank." That was used in the soft steel tank experiments. We had two soft steel tanks, No. 4 and No. 5; this is No. 4. We had three hard steel tanks, Nos. 1, 2 and 3, and this is tank 1 (indicating).

Mr. Lyon: We ask that the soft steel tank produced by the witness be marked DX-289.

(The tank referred to was thereupon marked DX-289.)

The soft steel tank, Exhibit 289, is made from material corresponding to well pipe. Well pipe is made out of soft steel. This was to show the action of acid in my tests on oil well pipe, on the iron used in well pipes.

The Court: Both the casing and the tubing? A. This happens to be a piece of casing, sixteen inch casing. We didn't use tubing because it would be too small. And the hard steel tank Exhibit 288 was made from hard steel and the defendant employes hard steel in its truck tanks. This is a piece of the steel.

Mr. Lyon: So as to show the effect of acid on the kind of steel that is used in the truck tanks as distinguished from the pipe.

The Court: Fine.

Mr. Lyon: Now let's get back over to the curves. Now, will you describe the experiment made the results of which are recorded in Curve No. 1 on Exhibit 280, just briefly, so we can tell what kind of experiment it was? A. Well, Curve No. 1 was a plain commercial hydrochloric acid placed in the hard steel tank No. 1 and agitated with the motor you see sitting on the tank over there, and a glass stirring rod used, for agitation, the R.P.M. of the stirring rod was about sixty revolutions per minute. And at each one of these points you see on the curve here a sample was taken, and an analysis for iron was run on that particular sample and recorded there, the amount of iron in ounces per thousand gallons of acid solution was calculated and plotted, versus time in hours. Also, I have a scale here which is iron content of acid solution in parts per million by weight, which was put on there to correspond to the values that the plaintiff gave us in their answers to interrogatories.

Q. Now, in making the test the numbers of which are plotted in the Curve No. 1 on Exhibit 280, did you have any lead plate bonded in the Tank No. 1? A. No lead plate at all in contact.

Q. Then this curve No. 1 on Exhibit 280 is a curve showing the rate of corrosion or dissolution of the hard steel tank in the absence of any lead plate using commercial hydrochloric acid; is that correct? A. That is correct.

Q. And that commercial hydrochloric acid is the same kind and make of acid as the defendant employes in its

acidizing operations? A. Yes. All these tests were run with fifteen per cent acid.

Q. All right. Now tell us what curve No. 2 is: A. Curve No. 2 was run in the exact procedure, however it was a different date. Curves 1, 2 and 3 were all run in the large steel tank No. 1 without any lead plate. As near as we could tell, exactly the same procedure. 1, 2 and 3 were run the same. They weren't the same acid. They were out of the same shipment of acid.

Q. I understand that you use one acid for the test, then you take another batch of acid for the second curve, is that right? A. Yes. Same base acid, same shipment.

Mr. Lyon: That shows, Your Honor, the three curves rather than an average. In that particular case, the three results instead of an average.

Mr. Owen: What make acid was it? A. Well, I just turned over to the purchasing department and told them to order so many carboys of the same acid we used in the field. I believe in that case it was Grasselli acid. I don't know.

Mr. Richmond: Mr. Clason can give the name.

Mr. Clason: Grasselli Chemical.

Mr. Lyon: You mean all these curves were made by the same Grasselli acid? A. Yes.

Mr. Owen: The same tank used for these tests, curves 1, 2 and 3? A. All on this sheet were made in one hard steel tank, and then we had three different sheets for three different tanks.

Mr. Owen: And the same shipment of acid? A. Yes, sir.

Mr. Lyon: Unless otherwise specified, you used the same shipment of acid for making all these tests? A. Yes.

Mr. Lyon: Now, I don't think I need to go into the date of the runs because they are all tabulated in Exhibit 285.

Mr. Wiles: The variation isn't attributable to temperature change at the different dates? A. Well, it might be because the same temperature might not prevail last Feb-

ruary in the building as it did this summer when we finally wound up the tests.

Q. (By Mr. Lyon): Now, curve No. 1, according to Exhibit 285 was made on March 31, 1941, Curve No. 3 made on March 5, 1941, Curve No. 2 was made on June 10, 1941. This was an air conditioned room in which these tests were made, is that correct? A. Yes. However, the temperature would vary from night and day too, you see.

Q. Well, these tests were run continuously, were they not, the number of days that your curve indicates? A. Yes.

Q. And are these the dates at the start of the runs? A. Yes.

Q. So Curves number 1 and 3 were both started in March, were they not? A. They are marked.

Q. And in that air conditioned room in your country there wouldn't be much difference in temperature as compared with one day in March to another, would there? A. No.

Q. And how much difference would there be in your air conditioned system between a date in March and a date in June in that room, if you know? A. I would say not over 5 or 10 degrees.

Q. Now will you take up Curve No. 4 on Exhibit 280 and tell us what that is? A. Curve No. 4 was commercial acid with a lead plate bonded to the side of the tank, as you see by the exhibit.

Q. Will you explain the bonding of this lead plate in Exhibit 288, which is a hard steel tank. Is the lead plate in the exhibit now bonded as it was in the test? A. It is. The lead plate that is bonded to the steel tank is the same —has the same surface exposed to the acid relative to the iron surface as the lead plate used in the defendant's truck tank (indicating). The lead plate was insulated by rubber stoppers from the bottom of the tank.

The Court: Is the lead in this tank exposed on both sides or on one side?

Mr. Owen: On both sides. A. After these experiments with the lead plate were run for twenty-four hours, the lead

plate was cut across here, the top, and then a stand was moved up and this lead plate was clamped in the acid, but not in any way connected to the steel tank, so as to leave the plate suspended in there, but no electrical contact except through the electrolyte.

Q. Now, this lead, what did you order, or, how did you get this lead plate; what kind of lead is it? A. It is the sheet lead just cut out of a piece of sheet which would ordinarily be used in the defendant's tank.

Q. Do you know what grade of lead it is? A. No; it is just the commercial lead.

Q. At the time you made these tests did you have any information, or anything which caused you to believe that the plaintiff in this case was relying on copper acting as an inhibitor in the Menaul system and there was any claim that there was copper in the lead or in the tank surfaces? A. No, I didn't.

Mr. Wiles: After you cut off the lead plate, how did you say it was held when the further tests were made? A. We moved a stand similar to this up here (indicating), and clamped this lead plate to the stand, metal stand.

The Court: Was that metal in contact with this part (indicating)? A. No, it wasn't, it was setting out here on the wooden table, you see.

Mr. Lyon: So what you did—we will point out the curves where you did it, and the end of twenty-four hours in these tests you disconnected the lead plate from the steel? A. Yes.

Q. Just to show what effect it made on the continued running when it was disconnected?

The Court: A good way to find out. All right.

Q. (By Mr. Lyon): Now, this lead plate in Exhibit 289 is subject to the same testimony and the same explanation? A. Yes.

Mr. Wiles: That is the soft steel tank? A. Yes.

Mr. Lyon: And these tanks, Exhibits 288 and 289, haven't been altered in any way as to their surface condition since you ran the experiments that your exhibits report? A. Except that they have rusted a little.

Q. They have rusted a little since then, but I mean you haven't done anything, burnished them or polished them or removed any corrosion, or anything of that kind? A. No.

Q. And any pitting that existed as a result of any of those experiments is still there? A. Yes.

Mr. Wiles: Do you have the composition of the steel in these tanks? A. No, I don't have.

Q. (By Mr. Lyon): But they are in the regular well pipe and the regular tank steel? A. That is right.

The Court: What did you do, take a casing and split it open and weld it on? A. We took a piece of 16-inch casing and cut out this piece about 14 inches high and then took a piece of the same material and made the bottom, welded the bottom in. It is the same material as the casing.

The Court: You took just one casing and cut it off and put the bottom in? A. Yes.

Mr. Lyon: How did you make the other hard steel tank, Exhibit DX-288? A. It was made out of a piece of flat steel, came out of the same stock as they make the defendant's tanks.

Q. How about the welding rods that were used? A. It was the same material as the tank itself.

Mr. Owen: Are the two tanks of the same capacity? A. Yes.

Mr. Lyon: And you used a lead plate in each case whose exposed surface relative to the exposed surface of the tank would exactly correspond to that relation in the defendant's truck tanks? A. I don't know whether it would be exactly or not. As well as we could calculate it.

Q. I mean, you calculated it, and, to the best of your ability, that is the relation? A. Yes.

Mr. Allen Owen: I would like to ask a question about the bottom of this soft steel tank. Where did you get that material? A. Out of a piece of casing.

Mr. Allen Owen: You took a piece of casing and flattened it out? A. Flattened it out.

The Court: Flattened out a piece of the same casing and then cut it out? A. That is right.

Mr. Wilber Owen: Did you heat the steel to flatten it? A. No. I don't know how they flattened it. They have hammers there in the shop.

Q. (By Mr. Lyon): They have big hammers down there that could easily flatten out one of these pieces without heating it, couldn't it? A. Yes.

Mr. Wilber Owen: You know that they didn't heat it? A. What they did, they took a welding torch and just cut the casing in two and then put it under the hammer and flattened it out. Yes; I am sure they didn't heat it.

Mr. Lyon: All right. Now, can we go back to curve No. 4 on Exhibit 280, and tell us how you made the test plotted on that curve? A. We ran the commercial acid with the lead plate bonded to the tank for twenty-four hours, taking samples, and at the end of twenty-four hours we disconnected the lead plate and left it suspended in the solution, insulated from the iron tank I described previously, and then took samples for an additional twenty-four hours.

Q. In preparing these curves, you have actually placed on the sheets the dots or points which your results or your measurements actually show, and by noting on these curves the dots you know exactly what readings and what calculations you made, is that right? A. Yes, sir.

Q. It is only necessary by means of this index to find in Exhibit 277 the values and the calculations that result in those particular readings? A. Yes, sir.

Mr. Owen: I would like to ask at this point whether you made any corrosion tests in those tanks without any lead plate connected with them? A. Yes. One, two and three were made without the lead plate. 4, 5 and 6 were made with the lead plate in.

Mr. Lyon: You have explained curve No. 4. Tell us how the test was run on which curve No. 5 was based? A. Curve No. 5 was run in the exact procedure as curve No. 4.

Q. How about curve No. 6? A. Curve No. 6 was the commercial acid, plus the Tergitol, which we originally felt might have been classified as an inhibitor, and it was run

with the lead plate connected for twenty-four hours, and then the lead plate was disconnected.

Q. This legend on Exhibit 280 reading "Lead plate disconnected, tank not cleaned," pointing to curves 4, 5 and 6, is to indicate that at the end of the twenty-four hours the plate in those three experiments was disconnected, and then the experiment continued with the lead plate suspended, and not connected, and without stopping to clean the tank? A. Yes.

Mr. Allen Owen: Was the tank cleaned between runs? A. Yes, it was.

Mr. Allen Owen: How? A. By putting in boiling sulphuric acid, and it staying in there about between 45 and 50 minutes, and at frequent intervals they would take it out, and if there was any contamination visible, they would brush it out with a wire brush; and then it was rinsed out with hot water, and then rinsed with hydrochloric acid.

Mr. Owen: How much Tergitol did you put in that last experiment? A. It was two-tenths of a per cent by weight.

Mr. Conner: Which Tergitol did you use for the last curve? A. Tergitol 4.

Mr. Lyon: At this time, in order that Your Honor may not be worrying about something that you don't need to worry about, I would like to read in evidence the answer of the plaintiff to interrogatory No. 7 proposed by the defendant to the plaintiff, and this was subscribed and sworn to on June 2, 1941, and reads:

(Reading): "7. Answer to Interrogatory No. 7. Plaintiff will not contend that the presence of 'Tergitol' in the acid solutions used by defendant in treating oil wells constitutes infringement of Grebe and Sanford patent No. 1,877,504."

Mr. Lyon: Will you explain the test by which the various curves occurring on this exhibit was made? A. These curves were made on tank No. 1 which was a hard steel tank, made similar to this other tank. Curve No. 1 was commercial acid, with no lead plate. Curve No. 2 was

commercial acid plus Tergitol, .2% by weight, with no lead plate.

Q. The first one is just the acid without any lead plate; the next with Tergitol without any lead plate at all? A. Yes. Curve No. 3 was commercial acid plus lead plate, with the lead plate disconnected after 24 hours. That was, it was cut and taken out, acid removed from the tank this time, and the tank thoroughly cleaned. And then the lead plate suspended back in the acid, the acid put back in the tank and the lead plate suspended.

Q. But not connected? A. Not connected in any way.

The Court: In other words, that means to me, as I look at it there, as quick as the lead was disconnected the acid went to eating the iron? A. The reason for cleaning this tank was to remove polarization or lead that was deposited on the steel tank.

Mr. Owen: Did you change the acid at that point? A. It is the same acid. Removed from the tank, placed in a crock, and after the tank was cleaned it was poured back into the tank.

The Court: Of course they cleaned it, so that if the others had done a good job, and all you claim for it, it might have such a coating on that it at least would take it some time to get started? A. Yes. Here (indicating) curve No. 4 is run in the same way, except the tank wasn't cleaned, and the curve came on out and eventually went up.

Mr. Lyon: What about curve 5? A. Curve No. 5 is commercial acid with lead plus Tergitol and the lead plate disconnected after twenty-four hours and the tank cleaned the same way as curve No. 3.

Mr. Lyon: The reason for these Tergitol duplications, Your Honor, the plaintiff doesn't contend the Tergitol is an inhibitor in measuring any claimed inhibitors or rate of corrosion in the defendant's acid; in order to be paralled with what the defendant uses; the Tergitol should be in there, because it is in the acid the defendant employs.

Q. (By Mr. Lyon): Now, will you turn over to the next exhibit, Exhibit 282, and explain the curves on that

exhibit? A. Curve No. 1 is commercial acid. This is a hard steel tank.

Q. No. 3? A. Yes; with no lead plate. Curve No. 2 is commercial acid plus arsenic trioxide. In the same tank. No lead plate. Curve No. 3 is commercial—

The Court: In other words, that is the patent? A. Yes.

The Court: All right. A. Curve No. 3 is commercial acid plus lead plate, connected up to twenty-four hours, and then the lead plate disconnected, but the tank not cleaned.

The Court: Ran straight on for a little while, they would have got rid of what was on the walls and then up they went. A. Yes. Curve No. 4, commercial acid plus lead plate, and at the end of twenty-four hours the lead plate was disconnected and the tank cleaned. Curve No. 5 is commercial acid plus Tergitol with lead plate connected for twenty-four hours. At the end of twenty-four hours the tank was not cleaned after the lead plate was disconnected.

Mr. Wiles: How was the tank cleaned? A. As I stated before, it was suspended in boiling sulphuric acid and then at frequent intervals they would raise the tank out and scrape it with a wire brush, and then at the end when it was taken out of the sulphuric acid it was lowered into boiling water and rinsed and then was rinsed with hydrochloric acid.

Mr. Lyon: Now, these three sheets, Exhibits 280, 281 and 282 are, in effect, a repetition of the same experiments, but using three different hard steel tanks? A. That is right.

Q. Just to show the results so that they may be seen to what extent they are consistent, using three tanks all made out of the same hard steel? A. That is right.

The Court: Like this one (indicating); have we got one of the three here? A. Yes, this is No. 1 (indicating).

The Court: The other two are not here? A. That is right.

Mr. Lyon: Now, will you turn to Exhibit 283 and ex-

plain the tests which resulted in those curves? A. This is a soft steel tank, No. 4, that we have here in the court room, and curve No. 1 is commercial acid, no lead plate. Curve No. 2 is commercial acid with no lead plate. Both of them were run for twenty-four hours. And, curve No. 3 is commercial acid plus lead plate, with the lead plate disconnected at the end of twenty-four hours and the tank not cleaned. Curve No. 4 was commercial acid plus Tergitol, plus lead plate, with the lead plate disconnected and tank cleaned after twenty-four hours. Curve No. 5 is commercial acid plus lead plate with the lead plate disconnected and tank cleaned after twenty-four hours. Curve No. 6 is commercial acid plus lead plate, plus Tergitol, with the lead plate disconnected and tank not cleaned at twenty-four hours.

Mr. Conner: Will you explain curve No. 4 with reference to curve No. 6? A. Curve No. 4 and curve No. 5 for the first twenty-four hours should be the same. They are commercial acid plus lead plate plus Tergitol. Curves 4 and 6 were run in the exact procedure, same procedure.

Mr. Conner: How do you account for that difference there, or can you? A. I can't; your explanation is as good as mine, I suppose. Curve No. 7 is commercial acid plus arsenic trioxide.

Mr. Wiles: I didn't understand which one of those had Tergitol in. A. Curve No. 4 and curve No. 5 was commercial acid plus Tergitol, plus lead plate connected for twenty-four hours. There was no difference in the materials used, or in the technique followed in curve No. 4 and curve No. 6. As far as we could tell, we carried out the exact same procedure.

Mr. Wiles: The same tank. A. The same tank, and curve No. 4, we got a much higher result than we did in curve No. 6, and I cannot account for it.

Mr. Conner: Which was first, curve 4 or curve 6? A. Curve 4 was 4/29/41; curve 6 was 4/22/41.

Mr. Wiles: Curve 6 was before the curve 4? A. Yes, a week before.

Mr. Conner: What did you do with that tank in between the time you ran the data as plotted on curve 7 and the time you ran the test as reflected on curve 4, what did you do in between those two tests? A. You mean what other curves I ran?

Mr. Conner: That, and what else did you do to the tank, if anything? A. Just cleaned it.

Mr. Lyon: You don't want to know about the other experiments he was running? They are all listed on this index.

Mr. Owen: In between those two dates, I would like to have the experiments pointed out.

Mr. Lyon: On this particular tank and not on the other tanks. A. As shown here, there was no other experiments run on this tank between the 22nd and the 29th. It just set idle. And then when we started to run curve No. 4 we cleaned the tank with the same procedure we had cleaned it before.

Mr. Conner: From running curve 4 as you testified and getting that value to running curve 6 as you testified and getting that value, I don't think you have got any reproducible curves there at all. A. Neither do I.

Mr. Lyon: You don't think you can make them, either? A. No.

Q. Now, will you turn over to Exhibit 284. Explain the tests which are graphically shown on that exhibit. A. This is soft steel tank No. 5; curve No. 1 is commercial acid plus Tergitol with no lead plate. Curve 2 and curve 4 are commercial acid—two duplicate runs without Tergitol, without the lead plate. And curve No. 3 and curve No. 7 was commercial acid plus lead plate plus Tergitol. For the first twenty-four hours they should be the same.

At the end of twenty-four hours, curve No. 7, the lead plate was disconnected and tank cleaned, while in curve No. 3 at the end of twenty-four hours the lead plate was disconnected and tank not cleaned. And curve No. 5 was commercial acid plus lead plate, and at the end of twenty-four hours the lead plate was disconnected and tank not cleaned.

Curve No. 6 was commercial acid plus lead plate, which was the same for the first twenty-four hours as curve No. 5, run in exactly the same procedure. At the end of twenty-four hours the lead plate was disconnected and tank cleaned. Curve No. 8 is commercial acid plus arsenic trioxide.

Mr. Owen: Is that the little short one? A. Yes.

Mr. Lyon: That was run for twenty-four hours? A. Twenty-four hours.

Mr. Owen: And how much arsenic trioxide did you put in that? A. One per cent.

Mr. Babcock: I think the witness made a slight error there, comparing curves 5 and 6. In one you had Tergitol and the other you didn't, did you not? A. No. The first had "Tergitol" there, but it is crossed out.

Mr. Conner: Shouldn't be there; is that correct? A. Shouldn't be there. "Tergitol" shouldn't be there.

Q. (By Mr. Lyon): Now, will you turn to the next sheet, and explain the tests that are graphically reported on this sheet. This is back again to a hard steel tank now? A. Hard steel tank No. 1. With sheets Nos. 6 and 7, we ran those after we had received the answer to the last set of interrogatories, where the plaintiff claimed copper as an inhibitor. Curve No. 1 is commercial acid, plus iron, lead, and copper added in the same amounts as claimed to be the analysis of the acid from the Zahn well. Curve No. 2 was commercial acid—I mean, C. P. acid, plus copper, the same amount, 3.1 parts per million. Curve No. 3 was the C. P. acid by itself. Curve No. 4 was C. P. acid plus lead, in the same amount as used in the Zahn well. Curve No. 5 was commercial acid without lead, and without anything added.

Mr. Allen Owen: That compares then with curve No. 3? A. No. Curve No. 3 is C. P. acid, chemically pure acid. Curve No. 5 is commercial acid.

Mr. Owen: What was curve No. 1? A. Curve No. 1 is C. P. acid, plus iron, plus lead, plus copper added in the same amounts as disclosed in the Zahn well, the acid used in the Zahn well.

Mr. Lyon: Have you explained all of these curves? What about No. 5 down there? A. No. 5 is commercial acid. No. 6 is commercial acid plus iron plus lead plus copper added in the same amounts as used in the acid in the Zahn well; the same amounts were added as in curve No. 1.

Q. Then the difference between curve No. 1 and curve No. 6, although those are duplicate experiments, or parallel experiments—or are they? A. All except that in curve No. 1 chemically pure acid was used, and in No. 6 commercial acid was used.

Q. Let us turn over to the next exhibit, 286. This is back again to the soft steel tank No. 4? A. Yes.

Q. What number is that soft steel tank? A. No. 4 is the one that we have here in the court room.

Q. These tests were made on the tank that is here in the court room? A. Yes.

Mr. Owen: What was the tank used in 285, was that hard steel or soft? A. That was hard steel, tank No. 1.

Q. All right, now will you explain these tests on which these curves were based? A. Curve No. 1, commercially pure acid plus lead.

Q. How much lead? Tell us the amount. A. The same amount that was given in the analysis on the Zahn well.

Q. The plaintiff's analysis? A. Yes.

Mr. Lyon: They reported in interrogatories, Your Honor, these amounts of lead, copper and iron which they found in these tank samples they took on these various wells, and they gave us that data.

The Court: And the witness prepared it synthetically the same as they did?

Mr. Lyon: That is right. I just want to see the date it was.

Mr. Babcock: The second day of June, 1941.

Mr. Lyon: That was June 2, 1941. That is the first time any of us had any idea, any suspicion, or hint they were going to claim there was copper in this system.

Q. And you made these experiments on 286 after we received that information as shown by Exhibit 285? A. They were made in June and July, Your Honor.

Q. Now, will you explain 286? A. Curve No. 2 is commercially pure acid with no iron, lead or copper or anything. Curve No. 3 is commercial acid as is used by the defendant. Curve No. 4 is a chemically pure acid plus copper, the same amount as given by the analysis in the Zahn well. Curve No. 5 is chemically pure acid plus lead, iron and copper in the same amounts used in the Zahn well. Curve No. 6 is commercial acid plus iron, lead and copper, the same amount as that used in the Zahn well.

Q. Now, just for a brief explanation of all these sheets of these curves, wherever the curve tends to go up more nearly as a vertical line, that means a higher rate of corrosion? A. Yes.

Q. And wherever it tends to lay down on a horizontal line, that means a lower rate of corrosion, isn't that right? A. That is right.

CROSS EXAMINATION

By Mr. Owen:

Q. Did you include in these charts, Exhibits 280 to 286, all the test runs that were made in these tanks that you have produced in evidence, and also all those which were run in duplicates of those tanks? A. No, I didn't; there are some curves at the first where I didn't pay any note to the tank number. I first started out with tank No. 1 and then I used another tank. When I started on tank No. 2 I didn't have the tanks numbered, and there was some there that I couldn't tell on which tank they were run, and they were left out. However, I think they will correspond to the curves that are shown. And then there are some others that were run using Petrowet instead of Tergitol, and there are one or two there with the C. P. acid where, after 24 hours, say I had been running lead in the C. P. acid, well, after 24 hours I would just put the same amount

of copper that was used in the Zahn well in the same solution and run it some more to see if it changed it any. That was just a preliminary experiment.

Q. That is not included? A. It is all in the data book, but it is not—all of it isn't in the curves on the curve sheets.

Q. Your data books contain every test that you ran? A. That is right.

Q. With any of these tanks? A. That is right.

Q. Now, how many of these hard steel and soft steel tanks did you make a test of? A. We had three hard steel tanks, that was tanks Nos. 1, 2 and 3; and two soft steel tanks, tanks Nos. 4 and 5.

Q. Were they all made at the same time? A. Yes—no, not all at the same time. Tank No. 1 was made first.

Q. That is of the hard steel? A. That is a hard steel tank. Then tank No. 2 next; and then tank No. 3. I can tell you when all of them were completed, when we had all five of them made. You can tell by the date of the test in here, when the tank was first run (indicating).

Q. How much time elapsed between the making of these different tanks? A. Tank No. 1 was made on or shortly before February 24th.

Q. Where did the material come from for that tank? A. It came from the same stock, from the sheet metal that was in stock that the defendant's tanks was made of, and this was cut out of a sheet of that.

Q. You mean your defendant's truck tanks? A. Yes.

Q. You make your own truck tanks, do you not? A. No, the Duncan Tank & Welding Company makes the truck tanks.

Q. Who puts the lead plates in them? A. We put the lead plates in. In getting the steel that I used for making these tanks I went to the Duncan Tank & Welding Company and told them what size tanks I wanted made up. I told them that I wanted them made up of the same steel, the same procedure in welding as we used in our truck tanks.

Q. Who determined the size of these exhibit tanks, and the shape of them? A. As I recall, Mr. Clason and Mr. Babcock and I had a conference, and decided what size tanks we would use.

Q. How many gallons do they hold? A. 11.4, I believe it is.

Q. How much acid did you put in each tank in each test? A. That was the amount of acid that we put in, which left the acid about half an inch, between a half and three-quarters of an inch from the top of the tank. We used the same amount of acid in each test.

Q. When did you make the second tank? A. The second tank was made about March 10, 1941. All this is in 1941. The first tank was made on or shortly before February 24th. The second one was March 10, in the neighborhood of March 10. I don't know whether it was on, before or after.

Q. And you told them you wanted the same thing? A. Yes.

Q. When was the third made? A. The third was made on or shortly before March 19. That is the first test that I have recorded for that tank, and it was made shortly before that. Both of the soft steel tanks Nos. 4 and 5 were made at the same time and at the same place and it was on or about April 2nd.

Q. Did you tell them how they were to be made? A. I told them to make them all out of the same material, what I mean is the soft steel tanks, out of well casing, 16-inch well casing.

Q. And the bottoms of all these tanks were welded in, were they not? A. Yes.

Q. Have you any analysis of this steel, either the hard steel or the soft steel? A. No, I do not.

Q. Now, you stated that you bought commercial acid from the Grasselli Chemical Company in carboys for use in these tests? A. Yes.

Q. And did you use more than one batch of—or more than one purchase? A. Of carboys, yes.

Q. How many? A. First we—the first order, we did not think we would run so many experiments, and, as I recall, we ordered about six or eight carboys, and then after we ran those we saw we were going to have to run some more experiments, and the last order, I believe, was for fifteen carboys.

Q. Do you know whether those came from the Cleveland plant of the Grasselli Chemical Company? A. No; I don't.

Mr. Clason: I don't exactly know the source, but I understand most of their acid is made up there.

Mr. Owen: Now, in this cleaning operation which you described, you stated that you used sulphuric acid. A. Yes.

Q. Where did you get that? A. I don't know where it came from. I got it—we have a plating shop, and they keep a sulphuric acid bath there. A plating shop.

Mr. Lyon: They have sulphuric acid they use in that plating shop? A. Yes.

Mr. Lyon: You went over there and got some of that? A. Went over and used the sulphuric acid bath to clean the tanks.

Mr. Owen: Did you dip it out of the acid bath, for the purpose, that is, out of the pickling bath? A. No.

Q. Did you get it yourself? A. No. Put the tanks in the sulphuric acid bath.

Q. Just as though you were pickling them; is that right? A. I don't know whether you would call it pickling or not.

Q. You submerged these tanks in that pickling bath, did you? A. Yes, in the sulphuric acid.

Q. Now, what do you use that tank for? A. Cleaning surfaces of metal.

Q. For getting them ready for plating? A. Yes.

Q. And how long did you leave these tanks in that pickling bath? A. Well, it ranged from about forty-five minutes to an hour.

Q. That was boiling? A. Yes.

Q. And what did you do after you took the tanks out

of the pickling bath? A. We rinsed them in hot water, and then we rinsed them with hydrochloric acid.

Q. What strength of hydrochloric acid? A. Fifteen per cent.

Q. You poured some hydrochloric acid in the tanks and sloshed it around, is that what you mean? A. Well, we rinsed them by just pouring hydrochloric acid in.

Q. Filling the tank and then— A. (interposing): We didn't fill the tank.

Q. How much did you put in? A. We put in about a gallon.

Q. Was that this same hydrochloric acid you were using in these tests? A. Yes.

Q. Poured out fresh acid from the carboys? A. Yes—no, we diluted it, of course.

Q. You diluted it to fifteen per cent? A. Yes.

Q. Now, who prescribed this cleaning operation? A. George Mahlin there in the laboratory.

Q. Who is he? A. He is the chemist in the Halliburton laboratory.

Q. Do you know what that pickling bath contained? A. Sulphuric acid.

Q. Anything else that you know? A. That is all that I know of.

Q. You don't know the composition of that sulphuric acid, do you? A. It was ten per cent, as I recall.

Q. How did you get that information? A. That is what Mr. Clason told me.

Q. That is, Mr. Clason told you that the pickling bath was a ten per cent sulphuric acid; is that right? A. Yes, sir.

Q. Do you recall what kind of tank that was in? A. It was in a steel tank, as I recall.

Q. You don't know whether it had any other ingredients in it besides that sulphuric acid? A. No, I don't.

Q. You have no sample of it? A. No.

Q. You never had a sample of it analyzed? A. No.

Q. Do you recall whether that pickling tank was unlined or lined? A. I wouldn't know whether it was or not.

Mr. Lyon: All these tanks were put in that same bath in the different operations in cleaning the tanks, weren't they, so whatever the bath did to the tanks it did to all the tanks each time they were cleaned? A. Yes, with the exception of about the first two or three that we didn't put in the sulphuric acid bath. Then we decided we would put them in there so they would all be cleaned in the same procedure.

The Court: Those are in your notes but not on the curves? A. Yes.

Mr. Owen: Now, these cleaning operations took place at different dates over a period of how many months? A. The first test was run from February 24th until about the first of July, I believe.

Q. And whenever you finished a test with one of these tanks, it was taken out and put through this cleaning procedure which you have explained? A. Yes.

Q. That is, you didn't wait and accumulate a lot of these tanks and take them out at the same time? They were cleaned promptly after the test? A. They were cleaned promptly before the test.

Q. So that the dates of the tests would indicate approximately when the tanks were cleaned? A. That is right. They were cleaned immediately before the test.

Q. Was this pickling tank being used in the regular commercial pickling operations during all that period? A. Yes, I suppose it was.

Mr. Lyon: I don't think the witness said that that was a pickling tank, Your Honor. I think that is being injected. I think he should be asked—

Mr. Owen (interposing): What was it? A. A bath of boiling sulphuric acid.

Q. What did they use it for? A. For cleaning metal.

Q. What did they do with the metal after it was cleaned? A. After the metal is cleaned then they plate it.

Q. Did you ever run any corrosion tests in one of defendant's commercial truck tanks? A. You mean the large size truck?

Q. The one that they use in delivering acid from the storage stations to the wells for acidizing operations? A. No.

Q. You had plenty of them around there at Duncan, didn't you? A. Well, there are some there, yes.

Q. Some there all the time? A. They are being made, shipped out all the time.

Q. But you never ran any test in one of those tanks? A. No, I haven't.

Q. The tanks when they are made by this Duncan Tank & Welding Company, they are delivered then to the Halliburton Company at its plant in Duncan, is that right? A. Yes.

Q. And then the Halliburton Company puts in these lead plates? A. Yes.

Q. And does the Halliburton Company also give what is called a polarizing treatment to the tanks before they leave Duncan? A. Most of them are before they leave Duncan.

Q. So that you have there in Duncan these tanks which the company uses in delivering acid from the storage stations to oil wells, both before they have been equipped with these lead plates and after they have been equipped with them, and after they have been polarized? A. Yes.

Q. As I understand it, the only tests that you made were on these cylindrical tanks which you have produced, or others made in accordance with them? A. Yes, sir.

Q. In some of these tests you stated that you added copper, lead and iron? A. Yes.

Q. Do you know in what form those metals were added? A. In the form of chlorides.

Q. Did you make the additions yourself? A. Yes, sir.

Q. You had the materials furnished to you by whom? A. They were in stock there in the laboratory.

Q. You weighed them out, the amounts that were to be put in these different acid baths? A. I did not weigh them. I made the calculations.

Q. What do you mean by that? A. I made the cal-

culations of how much weight was to be used, and one of my assistants weighed it out.

Q. Who put them in? A. As I recall it, I put in part of them, and part of them were put in by my assistants.

Q. Did you analyze the solutions either before or after you made these metallic additions? A. Not for the copper and lead; I just analyzed them for iron.

Q. Did you analyze them for any purpose? A. I just analyzed them for iron. We took a sample after we made up our solution, for our initial iron content.

Q. That was the only analysis that you made? A. That is right.

Q. You would take samples of the acid out from time to time and analyze them for iron? A. That is right, yes, sir.

Q. When you removed these lead plates by cutting them off and suspending them from another standard, as indicated in curves 4, 5 and 6 of Exhibit 280, who did that work, and where was it done?

Mr. Lyon: I don't think that is what he said he did, Mr. Owen.

Q. Then he can tell us what he did. A. The lead plates were not removed from the solution. They were just cut with a pair of tin snips, and the stand—the clamp on the stand was clamped to the lead plate, and the lead plate was left suspended in the solution all the time.

Q. And submerged to the same extent that it had been before? A. That is right.

Q. Who did that work of disconnecting the lead plate and resuspending it? A. Well, I did part of it, and of course I would have to have an assistant there to help me. There was generally two of us that cut the lead plate and clamped it.

Q. How did you cut it? A. With a pair of snips, tin snips.

Q. And how long did that operation take? A. Well, I would say about a minute; all you would have to do was to cut your lead plate.

Q. It wouldn't take any great length of time? A. No, it wouldn't take any great length of time.

Q. Now, referring to Exhibit 280, the first run indicated on that exhibit is the No. 5, is it not? A. You mean first in date? That is right.

Q. And the No. 6 run is the second in date? A. Yes.

Q. And the No. 3 run is the third in date? A. Yes.

Q. The No. 1 run is fourth? A. Yes.

Q. The No. 4 run is fifth? A. Yes.

Q. And the No. 2 run is sixth? A. Yes.

Q. Now turn to the next exhibit, 281. On that exhibit the No. 1 run was the first one, the earliest in date, was it not? A. Yes.

Q. And then the next one to be run was No. 4 on the exhibit, the next one is No. 2 on the exhibit, the next one is No. 5 on the exhibit, and the next one is No. 3 on the exhibit? A. Yes.

Q. Now turn to Exhibit 282. The first run on the exhibit is the earliest in date? A. Yes.

Q. And the fourth one on the exhibit is the next in date, the fifth one is the third in date, the second is the fourth in date, and the third is the fifth in date? A. Yes.

Q. Now, on Exhibit 283, the third one on the exhibit is the first in date, the first one on the exhibit is the second in date, the sixth one on the exhibit is the third in date, the fourth one is the fourth in date, the last one is the fifth in date, the fifth one is the sixth in date, and the second one is the seventh in date? A. Yes.

Q. Now, on Exhibit 284, the fourth run on the exhibit is the first in date, the fifth on the exhibit is the second in date, the second on the exhibit is the third in date, the third on the exhibit is the fourth in date, the first on the exhibit is fifth in date, the seventh is the sixth in date, the sixth is the seventh in date, and the eighth is the eighth in date? A. Yes.

Q. Now, these tests shown on Exhibit 285 used the same tank as that used in the tests shown on Exhibit 280? A. Yes; that is the first sheet.

Q. And there were six runs with that tank indicated on Exhibit 280? A. Yes.

Q. So the seventh run in that tank is the fifth one on Exhibit 285; is that right? A. The seventh run in which?

Q. In that tank. You see, there were six runs in that tank before these runs indicated on Exhibit 285 were run, and I want to get the order in which all of the runs were made in that tank. So we will refer to the earliest of the runs on Exhibit 285 as the seventh run in that tank? A. Well, it is the seventh run on this chart. However, there may be some of those others that I said I couldn't distinguish which tank they were in, in this tank.

Q. I want them in the order on this chart. A. On this chart.

Q. Yes. So that the fifth run indicated on Exhibit 285 was the seventh of the runs in that same tank? A. Yes.

Q. That is, of those that are shown on any of these charts? A. Yes.

Q. And the eighth run in that tank is the third run on this exhibit, the ninth run in the tank is the first one on this exhibit, the tenth run in the tank is the fourth on this exhibit, the eleventh run in the tank is the second on this exhibit, and the twelfth run in the tank is the sixth on this exhibit? A. Yes.

Q. Now, turning to the next exhibit, 286, was that tank used before on any of these other exhibits? A. Yes, it was used on sheet No. 4, the same tank as used on sheet No. 4. That is DX-283.

Q. DX-283, sheet No. 4; there were seven runs, that is right, isn't it? A. Yes.

Q. So that the eighth run in that tank would be the third run on Exhibit 286? A. Yes.

Q. And the second on the exhibit is the ninth in the tank, the fifth on the exhibit is the tenth in the tank, the first on the exhibit is the eleventh in the tank, the fourth on the exhibit is the twelfth in the tank, and the last one on the exhibit is thirteenth in the tank? A. Yes.

Q. Have you ever conducted any other corrosion tests of any kind? A. No.

Q. These are the first and only ones? A. Yes.

Q. Who directed you in the order in which these tests were made? No one? A. No. Mr. Babcock and Mr. Clason and I—

Q. (Interposing): You discussed each test and decided what the next test would be? A. We discussed what the general procedure would be, not as to individual test. What I mean, we didn't have a conference on each run. We would pick out certain groups to run and would run those. We would discuss those, and if there was any additional runs we decided we wanted to make, we would make them.

Q. How much of a group would you run? For instance, the very first test you made, how many did you outline for the first? A. The first test outlined was to run commercial acid on a tank representing our tank in the field, not using a lead plate; and then to run an experiment using the lead plate. That was all we thought at first run. After we ran that, we were curious and ran other experiments. We also agreed to use arsenate trioxide and Tergitol in that first set of runs.

Q. Well, now, will you point on this Exhibit 280 which tests were decided upon at the first conference before any of them were run? A. I probably could tell you better from this data book. We decided to run experiments shown as Curve 5, Sheet 1, and the one shown as Curve 6 on sheet 1. And the one shown as Curve 1 on Sheet 1. And I believe that was all on the first run. I don't know whether I could distinguish exactly which runs were run before we had another meeting.

Q. Well, I call your attention to the fact that the third curve on sheet 1 was run before the first one. A. Well, they are both the same runs. What I mean, they were run in exactly the same way. Both would be covered.

Q. Oh, 1 and 3 were run in the same tank? A. Yes, sir. We decided to run commercial acid in our tank, the commercial acid plus our lead plate, and commercial acid plus Tergitol plus lead plate, and commercial acid plus Tergitol, as I recall, in the first.

Q. Now, will your notebook show what your next plan was after those first runs were made? I suppose you had a consultation again. A. Then we decided to run some experiments using arsenic trioxide and Petro-Wet, and then run experiments where we had our lead plate connected and then disconnected and cleaning the tank after twenty-four hours, and after we had run those, then we decided to make up another hard steel tank, making three hard steel tanks and two soft steel tanks to duplicate the casing in the well, and run all of those using commercial acid and commercial acid plus our lead plate where the tank was cleaned and not cleaned after twenty-four hours. And the commercial acid plus Tergitol, and the commercial acid plus arsenic trioxide.

Q. Now, can you tell about when that conference was had? A. It was shortly before March the 31st, 1941.

Q. Well, then you proceeded to have these other tanks made up, did you? A. Yes.

Q. Then started in another series of tests? A. Yes.

Q. Now, can you point out, without giving the order in which they were made, the tests that were conducted in accordance with the plan laid out at that conference late in March? You have already given the order in which they were run. I just want to know which of these groups were run in accordance with that conference. A. Well, all of them are dated after that time.

Q. Then all of them dated later than March 31 were run in accordance with the plan made at that time? A. Yes—well, except that there are other plans where we used the ingredients of the Zahn well, that was made after we received our answer to the second set of interrogatories.

Q. Which of these groups would that be? A. Well, those were all made after June 10, on or after.

Q. Now, as to the order in which this second set of tests was run—I mean the large group that you ran after the second conference. Did you consult either Mr. Clason or Mr. Babcock as to the order in which those tests were run? A. No.

Q. That was left entirely to your judgment? A. Yes.

Q. Did you know what you were trying to show by those tests? A. We wanted to show what the lead, what kind of protection our lead plate gave, compared with commercial acid without any lead plate.

Q. You knew that you wanted to make a good showing for the lead plate, is that right? A. Sure.

The Court: When it was connected, you mean? A. Yes, sir.

The Court (to Mr. Owen): You meant to include that in your question, the lead plate when it was connected? You meant that, Mr. Owen—you meant to include that in your question?

Mr. Owen: Well, I did not ask that question.

The Court: When you said you wanted to make a good showing for the lead plate, you meant when it was hitched up?

Mr. Owen: Oh, yes, when it was hooked up to the steel tank, that is right. A. Yes.

The Court: In other words, that is their claim that—

Mr. Owen: Oh, yes.

The Court: And when it is disconnected, that is out. That was the way I understood it. Here is one question that occurred to me that I wanted to ask you, witness. In your effort to get the proportion of the steel exposed to the acid, and the amount of lead exposed to the acid, you tried to get that comparable to the steel and the lead of your transportation tank? A. That is right.

The Court: And did you take into account the fact that you, for instance, as to the iron, that you were not going to fill it within—the condition in your tanks too, I suppose, your transportation tanks, are they filled clear to the very tip-top? A. No, they are not.

The Court: And here of course this wasn't filled to the tip-top (indicating), and here is some of the lead, you took that into account, that this part over outside here of course wasn't going to touch it? A. That wasn't included.

The Court: You didn't include that, and the same

way for it a little ways down, for the lead here (indicating), was true of the iron to the lead, that the acid wouldn't reach all of the lead you would use? A. Yes.

The Court: But you took that into account as best you could? A. Yes.

The Court: To make the two comparable, and you have got your figures in there as to that, haven't you? A. I don't know whether I have the figures—

The Court: That is what you tried to do and you have shown us right here, anybody that wants to see it can? A. Yes.

The Court: But you did take that into account, that all of this lead outside of the iron tank— A. It wasn't calculated in, included in the calculation.

The Court: All right.

Mr. Owen: Did you consider putting the lead plate on the bottom of these tanks as it is in the transportation tanks used by the Halliburton Company? A. No, we didn't; we used it this way so we would be able to disconnect the lead plate easily without emptying the acid from the container.

Q. It would have been possible to put the lead plate on the bottom so as to make your tanks more nearly resemble the transportation tanks, wouldn't it? A. Yes, we could have, but when we disconnected the lead plate we would have had to empty the acid and it would have required more time.

Q. Referring to page 121 of DX-277, I find at the bottom of the page this note, "Lead plate was copper-colored at end of run." Can you tell me who made that note, and what it means? A. I made this note, and on this particular run—as you notice, we ran quite a few tests before this, and the motor, like you see here in the courtroom, was beginning to corrode; and after a run had started, we decided that we would provide some means of protecting this motor from the fumes; so we cut a piece of inner tube, and tied it around the motor with copper wire; and after we had stopped the run, and poured the acid out

of the tank, we noticed that the lead plate was copper-colored, very muchly.

Q. Was that copper wire in the acid? A. We do not know. We had already poured the acid out. We don't know whether there was any fragments left in, or not, or whether they had all been dissolved; but since it was the only one with the lead plate that was copper colored, we presumed that there was a chance for error there, that we might have dropped some of this copper wire in there.

Q. Do you know whether the copper wire that you used in tying this rubber around the motor was immersed in the acid, or any portion of it? A. No, it was not, unless it dropped in.

Q. It was up where it would be contacted by the fumes of the acid? A. Yes, sir.

Q. Which run is that on these charts? A. So for that reason we did not plot it on the charts, because we thought there was a chance for error in that.

Q. Where did that come in connection with the runs on the charts? A. It would be on the chart, sheet 2 (DX-281).

Q. In the order of the running of the runs, where would it have come on this chart? A. It would be between runs 2 and 3.

Q. You mean it was made after run 2, and before run 3? A. Oh, you are talking about the time? This test was run May 6, 1941.

Q. What did that run have in it, anything, in the acid? A. It had lead plate and Tergitol.

Q. Had it been plotted on this chart, Exhibit 281, the line would have passed through there? A. Yes, there were 82 ounces per 1000 gallons at the end of 24 hours (indicating).

Q. Is that where I have made this pencil mark, the little circle? A. Yes.

Q. If you will turn to page 130 of that notebook, at the bottom of the sheet there appears this entry: "At 9 o'clock next morning when emptied the tank was copper

coated and the lead plate was white (probably $PbCl_2$)." Did you make that entry? A. No, I didn't. Francis Anderson made it, I believe; it looks like his handwriting.

Q. Do you know any more about it than what appears in the entry? A. No, I don't.

Q. What run is represented by that sheet on the chart? A. That is test "T," a continuation of test "S," which was C. P. acid, which contained iron, lead and copper in the same proportion as that found in the Zahn well, and after 24 hours of test "S" we put a lead plate in the solution and connected it to the tank, which was called "Test 'T'," and after we had left the lead plate there and continued that run, when we removed the lead plate there was some copper coating on the iron tank and the lead plate was white.

Q. Now, will you point out on your chart which one represents Test "S" and which one represents Test "T"? A. I don't have Test "T" on this; I have Test "S" on the chart.

Q. Where would test "T" have come in the order of time on these charts? A. That was run for 13 1/3 hours, and in order to compare it with these, the initial value was already 490 ounces of iron per thousand gallons—in order to compare it with these I will have to substract this last value from the original value.

Q. You mean your solution tested 490 ounces of iron per thousand gallons when test "T" was started? A. Yes.

Q. Then how much did it test when test "T" was concluded? A. 511, which would be a difference of 21 ounces per thousand gallons.

Q. Then where we have mentioned parts per million we should have said ounces per thousand gallons all the way through? A. Yes. At the end of 13½ hours, 21 ounces per thousand gallons.

Q. Is that the right sheet (Sheet 1) where this test would have come in? A. It was a C. P. acid but we have no values with the C. P. acid run with lead plate to compare this with

Q. Well, I asked you to point out on the chart the point where this test would have come in the order of time had you recorded it on the chart. Will you do that? A. Well, in that case it would have been recorded—these are not made according to the time when they were run. They were made according to tank. It would have been either recorded here on PX-280 with the other lead plates and indicated as C. P. acid.

The Court: In other words, you haven't any chart it would go on unless you made a new chart? A. Yes.

Q. Well, will you point out where your test is on these charts? A. This is sheet No. 6. Test S is curve 1 on sheet 6 (DX-285).

Q. Now this test T as I understand, was run in the same tank and immediately following Test S, is that right? A. That is right. When we ran tests the corrosion was at this rate (witness indicating). When we put our lead plate in, connected it, at the end of 13½ hours our lead plate had given this amount of percentage as compared with the C. P. acid without the lead plate. (Witness putting dot on chart.)

Q. When you say this amount of percentage you have indicated? A. The end of 13½ hours the corrosion had increased 21 parts per million.

Q. And that is indicated where I make the pencil mark, circle, or dot on PX-285 (counsel putting dot on chart). A. Yes.

Q. Now, I want to get this perfectly clear. Your test S had what in the acid? A. It was C. P. acid plus iron, lead and copper added in the same proportions as used in the Zahn well.

Q. And then your Test T which followed immediately after Test S used the same acid but added the lead plate? A. Lead plate connected.

Q. And you used the same acid that had been used in Test S? A. That is right.

Q. Without changing the acid. A. Yes. It was cleaned. Yes.

Q. You poured the acid out of the tank and added the lead plate, and then poured the acid back into the tank, same acid? A. That is right.

Q. And the introduction of the lead plate reduced the rate of corrosion from—what is it up here? From about what? A. From about 322 down to about 21 ounces per thousand gallons.

The Court: But this, as I understand it, means it was not all due to the lead plate?

Mr. Owen: That is true.

The Court: That is right, isn't it, because the lead—this other— A. (Interposing): Well, the amount without the lead plate was 322.

The Court: Yes. A. When you added the lead plate, it brought it down to 21.

The Court: But it wasn't raw acid which you put the lead plate in? A. No.

The Court: So I can't give the credit to the lead? A. No, you can't.

The Court: In other words, as I understand it, your acid has brought it down to a point about here where my—

Mr. Lyon (interposing): Oh, no. A. Oh, no. Raw acid.

The Court: Raw acid. Then you put in these other ingredients? A. No; this is the same acid. It ate this much, and then we added the lead plate and it only ate this much (indicating on the exhibit).

The Court: That is the lead plate? A. Yes.

The Court: And this is the acid. These others don't enter into it at all? A. Don't enter into it at all.

The Court: What I said was wrong, as I understand it now. The lead plate, if that experiment was correct and I read the results, would do all the work of bringing it from the raw acid to there.

Mr. Owen: Oh, yes; the lead plate was the only thing added.

The Court: I thought he—I couldn't see why, but I got the erroneous notion that you had put that acid in, let

it work, or put those ingredients in and let it work, and it brought it down to there, and then you cleaned the tank and put those same old ingredients in, what had been used back in there again with the lead plate? A. No.

The Court: I was wrong. A. Yes. It was this acid here (indicating).

Mr. Owen: Now, as I understand you, in your test S which is No. 1 on PX-285, your rate of corrosion at the end of thirteen and a half hours is shown. A. Yes.

Q. At the end of thirteen and a half hours, in test S, your acid had how much iron? A. I believe I said 322 a while ago. But it is 332 ounces per thousand gallons.

Q. Then you continued that run how long? A. Twenty-four hours.

Q. And at the end of twenty-four hours how much iron did the acid have? A. It had 545 ounces of iron per thousand gallons.

Q. Then you poured that acid out, at the conclusion of run S, scrubbed out the tank as you have previously explained, that is by the boiling of it or putting it into this pickling bath, and letting it stay there for an hour in the boiling acid, and then removing and scrubbing it out with a wire brush and rinsing it with hydrochloric acid; is that right? A. That is right.

Q. Then you poured the same acid back into the same tank and put the lead plate in it?

The Court: Now, by the "same" you don't mean this old acid that he used? A. Yes.

The Court: You mean the new acid? A. No, the same acid.

Q. (By Mr. Owen): The same acid. You poured the same acid back?

The Court: As used in the run shown by curve 1? A. Yes. We removed the acid from the tank, cleaned the tank, connected the lead plate and then poured the acid back into the tank.

The Court: All right, now. Not fresh acid? A. No.

Mr. Lyon: Those different runs on these sheets used different acids.

The Court: I don't see how I am going to compare these when you are through, because this acid--this isn't this acid, this isn't this acid the way—when you start on this curve, it isn't the same condition it was in when it started on that curve. A. No.

The Court: All right.

Q. (By Mr. Owen): The acid that has been removed —that has been used in run S, was removed from the tank, the tank then subjected to this cleaning treatment, and the same acid was returned to the same tank; that is right? A. Yes.

Q. And then you added the lead plate to that tank, which acid had been in the test S? A. Yes.

Q. And then you ran it for thirteen and a half hours, and you found how much iron in the acid at the end of that time? A. At the end of that time, the total iron content was 565.5 ounces per thousand gallons.

Q. And then you—you say your added iron in that thirteen and a half hours would have been how much? A. 20.5 ounces per thousand gallons.

Q. So that after it had in all of the iron that was taken up in test S, it ran for thirteen and a half more hours after the cleaning operation and took up how much more iron? You just gave it to me. What was it? A. 20.5 ounces per thousand gallons.

Q. Now, at thirteen and a half hours, at the end of run S, how much iron did the acid eat up? A. 332 ounces per thousand gallons.

Q. That is in the thirteen and a half hours. The last thirteen and a half hours, I want. Of test S? A. May I have my calculation book? (After calculating): In the last 13½ hours of test S, the acid ate 217 ounces per thousand gallons.

Mr. Lyon: I would like to suggest to Your Honor that we don't know unless somebody asks at this point in the record, we won't know when he put the lead plate in whether it was bonded to the steel or not. Sometimes, as I understand it, they have the lead plate in without connect-

ing it to the steel, and sometimes they had them connected to the steel, and the record does not show now whether it was connected to the steel or not.

Mr. Owen: Is that your book? A. Yes.

Mr. Owen: I will ask him.

Mr. Owen: Was that lead plate bonded to the steel in your test T? A. It was.

Q. You didn't try a similar test to see what it would have been had it not been bonded to the steel? A. No, I didn't.

Q. At the end of test S, did you look at the walls of the tank to see whether or not it was coated with copper? A. I do not recall. It is not recorded.

Q. But you did notice at the end of test T, the walls of the tank were coated with copper? A. That is recorded here. I did not notice it myself.

Q. You did not make that note? A. No.

Q. On page 122 of this same notebook, there is an entry at the bottom, "Acid was black with suspended matter at end of this run." Did you write that on there, Mr. Hathorn? A. No, sir, I did not.

Q. Well, who did? A. I could not say.

Q. Have you got any explanation for it? A. No, sir, I have not.

Q. Will you point out on the charts which run that is? A. (Indicating): Here. This is DX-283, sheet No. 4, curve No. 5.

Q. That is the test that appears on page 122 of your notebook? A. Yes, sir.

Q. What was in that acid, anything? A. Commercial acid, plus lead plate.

Q. Anything else? A. With the lead plate removed and tank cleaned at the end of 24 hours. This was in soft steel tank No. 4 (indicating).

Q. Was it continued after the 24 hours? A. Yes, sir. The lead plate was removed, the tank was cleaned, and continued for an additional 24 hours.

Q. And then this note at the bottom of the sheet that

the acid was black with suspended matter at the end of this run refers to the end of 24 hours, or the end of the extended run? A. I would presume that it was at the end of 24 hours, because it is written under the—at the end of the first 24 hours.

Q. When the run was continued, was it continued with the same acid? A. Yes, sir.

Q. Have you any idea what that black suspended matter was? A. No, sir.

Q. Now, on page 127 of this same notebook there is a note, "No stirring since 8 8 8." Will you explain what that means? A. This is in plain commercial hydrochloric acid, with no lead plate, in hard steel tank No. 1; and after 24 hours we shut the motor off and allowed the acid to remain in the tank without being stirred from 1:30 P.M. to 9 A. M.

Q. Which run is that, and which chart? A. This is not in the chart. There was no agitation. We do not have any on the charts without any agitation.

Q. In the test reported on page 129 of this same notebook, the statement is made that iron, lead and copper were added to one crock. What were those crocks? A. Well, they were five-gallon crocks. Just ordinary five-gallon crocks used to mix acid in.

Q. Do you know how much copper, lead and iron was added to that acid in the test on page 129? A. The same amount as used in the Zahn well.

Q. The amounts are not indicated on this page, are they? A. No.

Q. Where are they indicated? A. I have the calculations. I believe they are indicated in the other book, the data book. There were added 380 parts per million of iron, 435 parts per million of lead, 3.1 parts per million of copper, this is by weight.

Q. Now, how do you connect that entry up with the entry on page 129 of the other notebook?

The Court: You mean how does he identify? A. The letter "S" is the same.

Mr. Owen: Now, I believe you stated that you did not weigh out these metal additions? A. No, I did not.

Q. Did you check the weights in any way? A. No, I didn't.

Q. You don't actually know how much copper, lead and iron went into these tanks? A. Yes, if their weights were accurate, and I trust them.

Q. You mean that you simply told them to put in so much and you relied on them to do it, is that it? A. Yes; I relied on them to make the weights.

Q. There is no entry in any of these notebooks, is there, showing the weights that actually were added to the different tests? A. Yes, on page 50 of DX-278.

Q. What does that show? A. Iron chloride was 85.7 grams, lead chloride 27.1 grams, copper chloride .387 grams.

Q. And that is what metals were added to test "S," is that right? A. In tanks Nos. 1, 2 and 3, and in soft steel tank No. 4—I mean iron chloride 88.5 grams, lead chloride 28 grams, copper chloride .398 grams.

Q. And you have only one indication of weights for tanks 1, 2 and 3, that is right, isn't it? A. Yes.

Q. You assume that those exact amounts were placed in each of those tanks? A. Yes.

Q. Now, when you cleaned these tanks after a run, how did you suspend them in the sulphuric acid pickling tank? A. They were suspended by clamping them to an electrical bus bar running over the sulphuric acid bath which was connected to electric current for making them the anode in the tank.

Q. What metal was that bar made of? A. I suppose it was made of copper, most bus bars are.

Q. Will you explain just how the tank was clamped to that copper bar? A. By a steel hook. A steel hook was hooked to the handle of the tank and then hooked onto the copper bus bar, allowing the tank to be suspended in the acid.

Q. How high above the top of the acid is this bus bar? A. It would be a guess. I would say about six or eight inches at least.

Q. Did it run across the pickling tank parallel with the surface of the solution? A. Yes.

Q. About six or eight inches above? A. I wouldn't say exactly six or eight inches but close to that.

Q. How far was the top of your tank from that bus bar when you hooked it onto the bus bar as you have explained? A. It was completely immersed in the solution. I would say it was at least 10 or 12 inches below the bus bar.

Q. I believe you stated what this pickling tank was used for. I haven't it in mind. Will you repeat that? A. I don't know whether you would call it a pickling tank or not, but it was used to clean the metals. We have our own plating shop. We do a lot of plating of our equipment. It is used to clean the metal surface in order to plate the iron, steel.

Q. Do you know what acid is used in that pickling tank? A. Sulphuric acid.

Q. Do you know whether any pickle control substance or acid regulator is used in that pickling tank? A. I understand there isn't.

Q. Just the straight acid, so far as you know? A. Yes.

Q. Did you ever test that acid during the time that you were cleaning tanks in it? A. No. However, since the tank was made the anode all the corrosion should have been on the tank. If there was any impurities on the tank it should have been removed since it was made the anode. This test tank was made the anode in the sulphuric acid solution so that any deposit that had been formed on the test tank would be removed electrically. That is reversing the procedure in which the tank had been coated; in our test it would be removed in exactly the opposite way.

Q. And that would remove any lead that might be on the surface, you think, of your tank? A. I would think so.

Q. How about copper? If there was any copper on the surface would that remove the copper? A. Well, if the copper was able to plate on in our test it certainly will be able to be removed in the cleaning tank.

Q. Now, did you make any test or analysis to ascertain whether or not the lead and copper were actually removed from the surfaces of your tanks by your cleaning operation? A. No, I think not.

Q. Do you know how frequently that acid was renewed in the pickling tank? A. No, I do not.

Q. Do you know whether it was ever changed? A. No, I do not.

Q. Do you know the conditions of these parts when they were placed in this pickling tank for removing the scale or whatever was removed? That is, were they dirty, had they been pickled before, how had they been handled and used? A. These tanks?

Q. No. The metal pieces which are placed in the pickling tank for the cleaning operations preparatory to cleaning. A. Most of the parts are just parts that have been machined in the shop, are taken directly from the machine shop to the plating shop.

Q. So that when they are placed in the pickling bath they are covered with oil, dirt and grease that comes from the machine shop? A. In some cases they may have some oil.

Q. After your tests that were indicated on these charts, did you analyze any of the solutions for lead, copper or other content than iron? A. No.

Q. When your tanks were put into this pickling tank, did they have the lead plates connected to them? A. You mean in the sulphuric acid?

Q. Yes. A. No.

Q. Did they have any portion of the lead plate connected to them? A. They had just a section where the lead was puddled onto the tank.

Q. That is where you sawed off the main section of the lead, the remaining part was on the bank, when you put it into the pickling solution? A. Yes, sir.

Q. And that was true in each case where the lead plate was used? A. Yes, sir.

Q. Before you used these tanks which you have de-

scribed, did you put them through any polarizing operation? A. No, sir.

Q. Do you know about a polarizing operation to which your regular transportation tanks are subjected? A. Yes, sir.

Q. But you did not do that to these? A. No.

Q. What if any check did you make on the acid that you used; did you check each carboy or each shipment, or what? A. The only check we made was when we made up our batch for the test, we made—that is, we took a sample before we put it in the tank, and analyzed it for iron content.

Q. That is the only analysis that you made? A. Yes.

Q. Will you explain just how you made the iron analyses? A. It is given in front of the calculation book, DX-279, on page 27. This is the procedure; I will read it. (Reading): "Bring to boil 10 m. l. of the acid solution; while hot, reduce ferric iron to ferrous iron with stannous chloride (using two drops excess). Dilute to 150 m. l., add 25 m. l. saturated mercuric chloride, 20 m. l. titrating fluid, 10 drops barium diphenylamine sulfonate indicator; titrate to purple end point with potassium dichromate."

Q. The dichromate solution. How much of that did you use? A. Well, you will have to refer to the—each one will be different for each titration. They are given in the data book.

Q. Will you look through that book and see if it is not true that in giving some you used less than one cubic centimeter of this titrating solution? A. I beg your pardon. If I am not mistaken, there was a factor on this titration fluid of 10.

Q. What do you mean by that? A. Where they have .0420 c.c. it was .420 used.

Q. Well, you say if you are not mistaken. Is there anything in this book to indicate that? A. I believe not.

Dr. Prutton: .420 is less than 1. A. Yes.

Mr. Owen: Well, now, in answering that question, you were referring to page 35 of DX-277? A. Yes.

Q. Now, will you explain the entries in the fourth column of the table on that page and state what you understand them to mean? Do they show the quantity of this titrating solution that was used in these different tests, or in these different analyses? A. Yes, I would say they did.

Q. And what are those? Read a few of those figures down, will you, from the top? A. Now, as I said before, there is a factor of 10.

Q. Yes. You read them and then I will bring that out. A. .0420, which would be .420 c.c. of titration fluid used.

Q. That would be your factor of 10? A. Yes. That is before the test started. That is the titration we got on the blank sample.

Q. Now, how much in ounces or in teaspoons would that .042 be? A. I think you will have to have some of the doctors figure that out. I don't know. I am not a chemist. The boys who made these titrations were chemists, all of them, and they made these entries.

ALFRED DOUTY,

a witness called on behalf of defendant, testified as follows:

DIRECT EXAMINATION

I am 42 years of age, reside at Elkins Park, a suburb of Philadelphia, Pennsylvania, and am the chief chemist of the American Chemical Paint Company of Ambler, Pennsylvania. As to my training in chemistry, I attended the University of Pennsylvania and studied chemical engineering. At the conclusion of the course I got a bachelor of science degree.

Mr. Lyon: What if any experience did you have in practicing your profession from the time you left school up to the time you became connected with your present company? A. From the autumn of 1919, the year when I graduated, until the summer of 1923, I was employed by a Philadelphia consulting engineering firm, Julian S. Simpson. The firm was engaged in general power plant consulting practice, including the study and treatment of boiler water for the prevention of scale, and also engineering problems connected with the efficiency and design of power plants. In 1923, in the summer, I became connected with the American Chemical Paint Company, at which time the main problem under investigation in the laboratory was the development of materials which were to conserve acid in the pickling of steel. I worked intensively on the inhibiting phase of the business up until about 1930. I also did work on many other products, including paints, cleaners for metal surfaces, soldering fluxes, and so forth. In 1930 I was given charge of the patent department of the company, in addition to my duties as chief chemist, and that meant that I was unable to spend as much time in the laboratory as I previously had, but since that time I have been directly in charge of the laboratory and we have had no less than one man at any time giving his full attention to the develop-

ment and study of inhibitors. Other men have been in charge of problems involving corrosion and its prevention generally.

I first started work with the American Chemical Paint Company in 1923 and have been with them ever since. I knew James H. Gravell of Elkins Park, Pennsylvania, named as the patentee in letters patent No. 1,678,775, granted July 31, 1928, which is DX-5 in this case. I knew Mr. Gravell very well. He was president and founder of the Americal Chemical Paint Company, and he was, at first, the only chemical expert the company had. As a matter of fact, I was the first chemist employed by the American Chemical Paint Company. Mr. Gravell at that time spent at least half of his time in the laboratory. He was a very brilliant man, although his formal training was not very great. And I worked beside Mr. Gravell a number of years. Of course, he had the duties of running the whole company, and he couldn't work continuously in the laboratory, whereas I did. It was not long after I had become connected with the company that we began to hire other men. But at first I worked with Mr. Gravell alone exclusively. Mr. Gravell died in December, 1939.

Q. You have said he was a very brilliant man. But I think the court would probably like to know a little more about him. It is a fact that he started this company with nothing but an idea, and what did he have that he made out of it when he died, just in a rough way, give the court an idea. A. I don't know whether it is pertinent to the issue, but in order to make clear what Mr. Gravell did, he started as an electrical engineer and he worked for the Hale & Kilburn Company in Philadelphia, who were making the early steel bodies, automobile bodies, and the early steel automobile bodies were rusting so badly under the paint that Hale & Kilburn were taking them back faster than they went out. And Gravell, in connection with a Philadelphia druggist by the name of George Feidt, conceived of an invention whereby they treated these bodies with a mixture of alcohol and phosphoric acid, which removed the

things from the surface which caused them to rust underneath the paint. And then he had—of course, he had the idea, and Gravell used to mix the things up in the morning to go out and sell them in the afternoon and they—it just happened to fill a great need, and so the company began to prosper.

Mr. Owen: How do you know all this, Mr. Douty? A. Well, I knew Mr. Gravell very intimately for about twenty years. I knew him and a great many of his friends. I have seen a good many of his records. He was a great expert on electric welding. He was an expert in the case on the Harmatta patent between Thompson Electric Welding Company and Ford Motor Company. I still have his file on that particular matter, which involves about ten large drawers of filing cards, and a number of larger drawers of data. I don't know that I know anything in life better than I know Gravell's accomplishments and mentality.

Mr. Lyon: Now, you had not finished your answer to my question. I asked you a question, that is, you told what he started with; can you give us an idea of how well he got along, and how he finished? A. Mr. Gravell will probably be best remembered by the public because, at his death, he left the entire company, which is valued at some millions, to a number of his employees, of which I am one. His company was extremely prosperous during his lifetime, and he died a very—well, I would say a moderately wealthy man at any rate. He did not leave any family. His wife had died just a year before he died, and he had no children. He had one brother.

Q. Now, when you went to work with the company in 1923, was the company interested in pickling agents, or inhibitors in any way? A. Yes, sir, it was.

Q. What was it doing that involved the use of inhibitors in acid at the time that you went to work with them? A. When I went with Mr. Gravell, he thought that he—he had been investigating agents that he had heard of that were being sold in Europe, which were said to reduce the attack of acid on steel during pickling, and to save

money; and he had investigated a number of agents, of which he had come across one which seemed to him to have promise. He felt that his training in chemistry was inadequate, and he hired me, because he felt that he needed someone of more training, to investigate systematically the field of inhibitors. And that was my first work. And I, although it was new to me, was able fairly shortly to develop techniques for preparing inhibitors, which went beyond anything that Mr. Gravell had thought of at the time; and it was not long after I got with the company that he began to exploit a material which was known as rodine, and rodine has ever since been the generic term for the kind of inhibiting agents which we sell to the trade for various purposes.

Q. You heard the depositions read here concerning the use of an inhibitor by the Gypsy pursuant to Dr. Westcott's deposition. A statement was made by several witnesses the inhibitor used there was rodine purchased from the American Chemical Paint Company along about 1928, '29 and '30. Were you selling such a material under that name at that time? A. Yes, sir.

Q. Do you know what it was? A. Yes, I do.

Q. Was it an inhibitor for hydrochloric acid? A. Yes.

Q. What was its chemical composition, if you know? A. It was a hydrochloric acid solution of basic materials extracted from a waste product known as bone tar oil or known to the chemists as Dippel's oil. That product was obtained by the distilling of bones—in fact, it consisted of a number of bases wherever protein material is distilled in the presence of fat. In fact, in the presence of the aldehyde acrolein. The basic materials are extracted from the tar oil by mixing them with hydrochloric acid. It then separates an upper layer of oil which is worthless and consists largely of nitriles of higher fatty acids and also a certain amount of tarry material, and there remains a clear hydrochloric acid solution which is the material that is sold as Rodine, or was originally sold as Rodine No. 2.

Q. You have read Dr. Westcott's report, which is in

evidence in this case, have you not? A. I have heard it read.

Q. And you heard what Dr. Westcott had to say in that report as to what Rodine No. 2 would do in protecting well pipe when the acid was being introduced down into the well? A. Yes, sir.

Q. Is it a fact that Rodine No. 2 would produce the result which Dr. Westcott stated in his report it would produce? A. Certainly.

Q. Now, were you aware of the making of the discovery or invention which is set forth in the patent involved in the defendant's counter-claim here, Gravell Patent 1,678,775? A. Yes, I was.

Q. You were aware of Mr. Gravell's work at the time he made that discovery and know under what circumstances it was made? A. Yes.

Q. Before I ask you to give us that history, would you take and refer to the patent itself and tell us what you understand the invention to be, covered by that patent? A. Before I can state what I consider the invention to be, I would have to give you a very brief outline of the state of the knowledge at the time Gravell made this invention, so that the terms he uses, the materials he refers to, may make some sense.

Mr. Lyon: All right.

(Witness continuing): Up to the time of Gravell, there had been a number of patents and references in the literature to substances capable of reducing the rate at which acids attack metal. The only use that had ever been made of that information, as far as I have been able to determine, was in the addition, usually, of organic substances, to the pickling baths in which scale is removed from steel, to reduce the unnecessary loss of metal. Now, scale is removed from steel—scale, by the way, is generally—I mean the oxide which is formed when steel is heated during the fabrication process prior to rolling or forging.

Now, in pickling off that scale the common agent in this country is sulphuric acid. Hydrochloric acid is used

more commonly in Europe. But, sometimes hydrochloric acid is used here. Mill scale is very resistant either to hydrochloric acid or to sulphuric acid, but it is more resistant to sulphuric acid, and the scale is not removed from the steel by being dissolved therefrom; it is removed because it is full of cracks, the acid gets down through the cracks and eats the metal out from under it, and as the metal is eating out from under it hydrogen is generated and the hydrogen gas gets in behind the scale and the scale appears to be either slid off or blown off in flakes when it sinks to the bottom of the bath.

Now, in that operation it is inevitable that some metal be dissolved. The removal of scale from steel is practically impossible to accomplish without the removal of some metal. However, scale is not generally uniform on a piece of steel; it is heavy in some spots and not so heavy in others, or it is more cracked in some spots and not so much cracked in other spots. Therefore, if you have a large piece of steel and are pickling it, the scale may be all off of one end while it is still quite firmly attached on the other, and it is necessary to protect the sound metal, which has been pickled, during the rest of the necessary period until you get the scale all off of the end on which the scale remains.

Well, with that as a preamble, and getting a sort of the state of the art at the time Gravell got into the picture with his patent. Gravell made the interesting discovery that the substance, arsenic, which had been previously mentioned as a restrainer, when used in connection with organic inhibiting materials, really organic inhibiting materials, gave a degree of protection to the metal which had not heretofore even been dreamed was possible. In other words, a degree of protection such that an iron nail, ordinary steel nail, could be put into a ten per cent sulphuric acid solution containing, let us say, a good organic inhibitor such as this solution of organic bases, plus some arsenic, and left there for months and months and months at a time without being apparently affected at all.

Now, arsenic had some great disadvantages in the

pickling of steel. Its use as an inhibitor was originally suggested by a fellow named Meurice, back in the 1880's. Meurice had a wire mill in Belgium, he was the manager; and he found that the wire seemed to be smoother and less corroded when he put arsenic in the acid than when he did not. This he discovered accidentally, because he found that he had two kinds of sulphuric acid from two different sources, and one of them seemed to give him a smoother wire, less breakage in his drawing operation, and certain other advantages over the other one; and he finally traced that down to the fact that the acid had arsenic in it, or considerably more arsenic than the other one. However, sheet mills had never been able to use arsenic. In fact, the use of arsenic as an inhibitor was patented in this country back in 1908. I think that that patent will ultimately be mentioned. Burgess in 1905, at the University of Wisconsin, investigated the effect of arsenic rather completely. The only thing was that nobody was able to make any use of this knowledge.

Arsenic has a curious property, it prevents steel from pickling clean. If the scale is at all rolled into the surface in a peculiar form, and you have arsenic in the bath, the scale won't come out; so that when you go to de-form your steel for your next operation, it has acid spots, and you get trouble either in the finish obtained, or you get trouble with the equipment with which the steel is processed. So that nobody made any use of arsenic. That has been known for a good many years, but nobody had used it.

When Mr. Gravell found out that arsenic, together with these inhibitors, had such a tremendously powerful restraining effect, and almost stopping effect, he felt that that solved a problem that had been bothering our company for a long time. We were shipping organic liquid, I mean, acid liquids, notably this product I have spoken about, which contained water, and phosphorous acid and alcohol, first, in wooden barrels, and since we had trouble with this liquid, we shipped it in rubber lined barrels of our own design, and our own manufacture. Now, those were expensive barrels.

they would only stand up for a few trips, and I have forgotten how much they cost us apiece, but I think it was well over $8. When Gravell found out that arsenic in an organic substance as a restrainer, an inhibitor, had this powerful effect, he immediately saw that this was an answer to the problem of shipping acid or other liquids in steel containers, and he tried it out and it worked very well. And we shortly thereafter started the shipping of some acid liquids in steel drums. Now, our inhibiting agents sometimes had arsenic added to them, that is to say, our rodines. But in small quantities, so that by the time they reached the customer we hoped that all the arsenic would be gone.

Mr. Lyon: This is before Gravell's invention you are speaking of now? A. No, I don't think it is. We had never used arsenic as an inhibitor, because before that time we had known of its disadvantages. But Gravell, when we —our inhibitors were acid liquids also and contained large quantities of inhibitor, but still we shipped them at first in glass. And by adding a certain amount of arsenic to those materials we felt that they would be safe to ship in steel. In any case, the net result was that shortly after this discovery we shipped many, many thousands of drums, steel drums of quite acid liquids all over the country, without having—without having had any appreciable trouble.

Q. Now, before Gravell's discovery, which is—upon which this counter-claim patent is based, to your knowledge had corrosive acids ever been shipped in steel containers? A. No. Not truly corrosive acids. That is to say, concentrated sulphuric acid has been shipped in steel containers, but that is not corrosive to steel appreciably when the concentration exceeds, oh, about ninety per cent.

Q. How about hydrochloric acid? A. I have never heard of hydrochloric acid being shipped in steel, and I don't believe it ever was, before that time.

Q. Before the discovery on which this counter-claim patent is based? A. Yes, sir.

Q. That is, all hydrochloric acid had been shipped in what kind of containers? A. Usually glass carboys.

Q. Mr. Douty, you were explaining the counter-claim patent and its relation to the art. I don't believe you finished when we adjourned. So will you continue? A. Well to summarize, what I said before on this subject, I think that the principal contribution of this patent is this: That although arsenic had been known to reduce the attack of acid on steel any reasonable amounts of arsenic were deleterious in pickling processes generally, and therefore arsenic had never come in use as an addition agent in pickling baths.

Secondly, Gravell was the first to discover that organic materials which had restraining power on the action of acids on the metals co-acted with arsenic and certain other metals to give a very much more powerful inhibiting effect. Although the term "inhibiting" had occurred in the prior art, I don't think it had ever occurred to anyone else that inhibiting in the sense of practically completely stopping corrosive action and could be accomplished by the use of these agents. I think, therefore, that the principal point of this patent is this—that nobody had ever conceived it possible so completely to reduce the attack of acid on steel as to make it safe or practical to carry acid solutions in steel containers. Gravell gave definite examples of combinations which would be suitable for that purpose.

Q. Well, I understand from the testimony, Mr. Douty, that for some period of time the plaintiff employed arsenic as the inhibitor, arsenic trioxide, in accordance with the proportion given in the Grebe-Sanford patent here in suit. Will you tell us whether or not such an inhibitor is a material capable of precipitating a substantial protective coating on steel? A. Unquestionably.

Mr. Owen: We admit that is true—that arsenic does have that property.

The Court: With all these patents, unless it be the—well, I will just talk about the two of them; I am talking about this one here (indicating). I have not analyzed the others to see how they are, but our No. 1 patent and this one run crosswise. One covers transportation for one purpose, and the other for another purpose.

Mr. Lyon: Of course, our position is that our patent very much antedates theirs, and if there is any conflict, the latest patent is the one to fall. Maybe when Your Honor gets through we will both of us lose them, but I don't think you should hold it against the earlier patent, that there is a conflict with a later one.

The Court: Hasn't somebody got a patent for putting an inhibitor in that would take care of all purposes? Didn't anybody get a patent to that effect? A. Not as far as I know, Your Honor, and I have been over it very carefully.

Mr. Lyon: The fellow who invented inhibitors would probably have objected to all of these patents on the ground that under the law he had all of the benefits of his discovery, and if it was good in tanks, he was entitled to that, and if they were good somewhere else, he was entitled to it.

Mr. Lyon: Mr. Douty, suppose you tell us what your views are as to the comparison of Gravell's invention, with what the plaintiff does when it is transporting the acid down their pipe in the well? A. Well, to follow along the argument that Your Honor has just put forth, it seems to me that if there was a patent with a method of preventing an acid solution from attacking a steel transportation or storage drum, and I think one can say this is a container made out of steel, that is, a pipe line is a container made out of steel, as I conceive it, the plaintiff does not claim it has any function in going down this pipe line whatsoever; the Grebe and Sanford patent, as I understand it, is a method, and is written on a method of getting that to certain formations, that acid, and you cannot treat it until your acid gets into the formation, and the only way you have got of transporting it down there is to put it through the steel pipe. I cannot see that the steel pipe of the plaintiff, or of the defendant, is any different than the storage or transportation container of Gravell. They are both made out of steel, and the problem in both cases is to keep the acid from eating, and Gravell found a pretty good way of doing it.

Q. You referred to Gravell as including containers. I call your attention to the eighth line, the second word in

the eighth line on the first page of this Gravell patent, where he says, "Steel drums or containers." Now, is the problem of protecting steel transportation drums, or containers from the corrosive action of hydrochloric acid by inhibitor any different in the case of a tank or drum on a railroad car, or on an automobile truck, than it is in a well pipe, going down a well? A. No, only the one, of protecting the steel drum on a truck is a little more difficult problem. The drum on a truck is supposed to keep the acid in it for hours, days and weeks. The pipe has acid in it for a few hours at most.

Q. Now, just to make one point clear, does it make any difference as to protecting the transportation tank or container whether it be on a truck or on a railroad car, or a pipe down a well, what happens after the acid leaves the pipe or container, what you do with the acid or what you are using the acid for after it leaves the tank or the pipe? A. As long as the purposes for which you are going to use the acid are not in any way interfered with by the substance you put in it, it doesn't make any difference how you transport it to the spot where you are going to use it, obviously.

Q. There can't be any argument, is there, but what while the acid is going down the well pipe the pipe is a container for the acid? A. No.

Q. Now, I believe you have testified, have you not, as to the circumstances under which this discovery or invention covered by the Gravell counter-claim patent was made by Mr. Gravell? A. Yes.

Q. Were those facts given from your own personal knowledge? A. Yes, such facts as I have given are from my own personal knowledge.

Q. Can you fix the date, or a date prior to the filing of the application for this Gravell patent, on December 11th, 1925, at which time Mr. Gravell was—had made this discovery, of your own knowledge, and can you produce any original record from your company showing and referring to that discovery? A. I have the original record book and I will produce it. (Producing book.)

Q. What can you state as to the date this record was made in view of the date appearing on the record, October 29, 1924? A. I know that this material had been reduced to a commercially feasible product and had actually been tested in practice at some time before that date.

Q. Did you see this record on or about October 29, 1924? A. As a matter of fact I believe I got this formula up. Although Mr. Gravell's name appears on it as approving it, I actually got up the formula.

Q. Under his direction? A. Yes.

Q. Now, were there any further formulas for this patent following this date of October, 1924, and up to the date of the application for the counter-claim patent, which was filed on December 11, 1925? A. Yes, there were a number of them.

Q. Have you any more formulas for this same invention of the counter-claim patent in this record prior to December, 1925? A. Yes, I have. I want to point out that that particular embodiment of the invention described at the top of page 2 on the left hand column is by no means the only embodiment. That particular material is, in itself, meant to be transported in steel and then to be useful as an inhibitor to be added to pickling baths or for any other inhibiting purpose.

The Court (interposing): The real purpose of this was to fix it so you could transport it? A. Yes, sir.

Q. As I understand your testimony, these formulas were not entered in this formula sheet until they were completed experimentally and actually placed on sale, is that correct? A. That is correct.

Q. As standard products of your company, or regular products of your company? A. Yes.

Q. Now, have you any further records showing formulas under the counter-claim patent prior to December, 1925? A. I have a formula here which coincides very closely with the formula given at the head of the second column of page 2 of the Gravell patent. This is the material known as Rodine No. 4, our formula No. 103, dated March 14, 1925.

Q. Will you compare that with the corresponding formula in the patent? A. This formula is essentially identical with the formula in the patent. I do not see any significant difference. There are more things in our formula book than appear in the formula in the patent, but the end result is exactly what is given by the formula at the top of page 2.

Q. Mr. Douty, did your company ever practice the shipping of any of these products in steel containers? A. Yes.

Q. Can you state when that practice commenced? A. I can't give you an exact date and there is nothing in these formula sheets that tells me the exact date, but I do know that the purpose of putting the arsenic in every one of these formulas was so they could be shipped in steel containers. There wasn't any other purpose in putting the arsenic in. So I am quite sure shipment of these materials in steel containers began certainly somewhere in the neighborhood in the time corresponding to the dates on the formulas, or before.

Q. Well, as a matter of your own independent recollection, can you remember that there were such shipments? A. Yes, I can. But I can't fix the date any better than by referring to the sheets.

Q. Now, just tell us what your company shipped in steel containers, beginning as near as you can with the dates that you have indicated. A. It certainly shipped the products to which I have already referred in steel containers, with the possible exception of the Scaline, because I don't know of my own knowledge that that was ever shipped in steel; the others I do know were shipped in steel. When the others began, I can't say. In addition to the products I have already mentioned, both arsenic and inhibitors of the type mentioned in the Gravell patent were likewise customarily added to certain of our other products, so that those other products could be shipped in steel containers, to my knowledge.

Q. Then, based on your recollection and based on what

assistance you get from this record, about what period, as near as you can fix it, did this shipping in steel containers start? I am not asking for an exact date but a safe date. A. A safe date would be somewhere in the last third of 1924.

Q. And after you once established that practice, to what extent did you continue it? The practice of shipping in steel containers? A. The practice continues to the present day. All acid liquids which are not otherwise deleteriously affected by the presence of materials like arsenic and our inhibitor of the Rodine type, of the early Rodine type, are still so shipped. And that means a great deal of liquid is so shipped.

Q. Can you give the court a picture of how much business you have been doing since 1924 with these materials containing these agents in steel containers, what industries they were shipped to, what the materials were, and some idea who the customers were. A. Well, materials of the type described in the first two formulas which I gave, have been shipped very extensively to the steel industry for use in the pickling of steel over a long period of time. Now, I can't give you a definite idea of how much business that was except that I know that it amounted to an average of possibly some hundreds of drums of that particular compound per year. In addition to that, there have been many more hundreds of drums of our body cleaner Dioxidine shipped in steel by the aid of additions of arsenic and other organic material of an inhibiting nature.

Q. What were you shipping that Dioxidine in to the automobile or paint industry prior to Mr. Gravell's invention set forth in the counts in patent? A. At first in glass, then in wooden barrels, and then when those wooden barrels leaked too badly Mr. Gravell developed a new type of rubber lined barrel, on which he had a patent.

Q. To what extent did this counter-claim invention of shipping in the steel containers replace those other forms of containers? A. It replaced them altogether. I must modify that statement—to the extent that we still supply

the Oxidine to such retail customers as can only buy a gallon, in gallon bottles, but other than that we ship quantities from 10 gallons upward in steel.

Q. Did you give, or can you give any estimate of the value of the products that have been shipped under this counter-claim patent by your company in steel containers, just as a round figure? A. Well, it would be pretty much of a guess.

Q. Well, make a conservative estimate. A. Well, it would be something over two million dollars, and something under ten million dollars worth, but I cannot tell you exactly.

Mr. Owen: You mean that you shipped in steel containers? A. Yes, products of that value.

Q. Can you give us the names of a few of the representative customers that such shipments have been made to? A. Oh, yes. Hudson Motor Car Company, Packard Motor Car Company. Shipments were made to the Studebaker Company, the Ford Motor Company, Chrysler Motor Company. United States Steel Corporation, to its various plants all over the country, including the Carnegie-Illinois Steel Company, and various other branches. I would say practically to every, pretty near every representative motor or steel company—I would say that they have at some time or another received products shipped in steel, the steel containing materials in accordance with this patent.

Q. You have covered the steel industry and the automobile industry. What about the oil industry? A. Well, in the oil industry, among other people, we have shipped to the Dow Chemical Company.

Q. About when, do you have any dates? A. I don't remember exactly when, but I have seen the invoices, so I know we shipped to them.

Q. Have you any idea when it was? A. Well, I think it was probably around 1934 or 1935.

Q. Any oil company? A. We have shipped—we did some business in the south, in the southwest, through Tulsa agents, whose names have escaped me for the moment, we

sold quite a little rodine down there, as far as I know to oil companies, but I cannot be sure of that. I have seen invoices where we shipped some Rodine No. 2 to the Gypsy Oil Company.

Mr. Owen: I would like, Mr. Lyon, at this point, if you would please have the witness identify a little more definitely these materials which were shipped to these different industries.

Mr. Lyon: Well, I will be glad to do that.

Q. If you can elaborate on that, Mr. Douty, or fill in that testimony that Mr. Owen asks for, if you can, give him what he wants? A. Well, the automobile industry got mostly body cleaners, containing phosphoric acid, alcohols, rodine and arsenic.

Mr. Owen: What were those body cleaners called? A. Deoxidine. They also got some Deoxiline.

Mr. Owen: Have you got the formula for those? A. Why, yes, but I am not so sure that I care to give it to you, because some of them are still in use.

Mr. Owen: They contain phosphoric acid? A. Yes.

Mr. Owen: And no other acid? A. No other acid.

Mr. Owen: What did you ship to the Dow Company? A. I am not sure that I know right now; either Rodine or Murodine, I can't remember which.

Q. What was Murodine? A. Murodine was a material, an inhibitor made under certain other patents not in suit here. It did not contain any arsenic.

Mr. Lyon: Did the—do you believe it corresponded to the claims of this counter-claim patent here in suit? A. I am inclined to believe that—

Q. (Interposing): It would depend how it was used, I suppose.

Mr. Owen: It would depend on what it contained. A. Well, in any case, it wouldn't correspond to the claims of the patent, because, as I recall, we didn't ship Murodine in steel at all.

Q. Do you remember whether you ever shipped any Rodine in steel to the Dow Company? A. I can't re-

member. If we ever did, it would appear in the deposition of Mr. Spruance.

Mr. Lyon: We will turn to a new subject now, Your Honor. I want to have the witness present patents which will be relied upon by the defendant as constituting the pertinent prior art ahead of the Grebe-Sanford patent in suit. I will try to do that as fast as I can. Of course, we are permitted to rely on such of those as the plaintiff has already offered in evidence, and I don't think it would be necessary for me to go over those again. But we have some others, and I would like to mark this group of patents as DX-294, and I will identify the patents at this time.

(Whereupon the group of patents referred to was marked DX-294.)

Mr. Lyon: Now, Mr. Douty, can you go through these various patents and identify which ones you are talking about and tell us in so far as they are pertinent here what they disclose and see if you can classify them in some way that will help the court. I have in mind if they only show inhibitors for corrosive acids, say that that is the classification they belong in. If they show adding inhibitors to acid for removing limestone scale, or some such particular purpose analogous to the Grebe and Sanford patent, that you call attention that they fall in that class. I think that will help the court the most, because I do not think there is anything very difficult about these patents, Your Honor. It is just a question of getting them classified and getting them in your mind. A. I had thought that logically the prior art patents really belong into three classes: those which indicate the general principles of inhibiting, what inhibitors have been used for, and how generally they have been applied; those which showed particular inhibitors mentioned in the patent in suit, the Grebe and Sanford patent in suit. Before I read any of these, or refer to any of the patents, I just want to go briefly over the list of inhibitors to which Grebe and Sanford specifically refer. Grebe and Sanford specifically refer, toward the bottom of column 1 of page 1, to arsenic acid, to arsenic trioxide, or a

soluble arsenate or arsenite. Toward the bottom of column 2 of page 1, Your Honor, they begin to tell what inhibitors they have in mind. And in addition to those arsenic compounds Grebe and Sanford refer to other inhibitors such as cyanides, organic nitrogen bases such as aniline, phenylhydrazine, pyridine, quinoline, acridine and derivatives thereof, organic sulphur compounds such as mercaptans, as well as various by-products of industrial processes, such as sludge acid from oil refining and residues from acid sulphite paper manufacture.

Referring now to the Laverty patent No. 856,644. That is the first one in the book after the Frasch patent, Your Honor.

The Court: Maybe someone will tell me, now that I am starting with this, was this both in the file wrapper and before the Tenth Circuit?

Mr. Lyon: Yes. This one was cited by the Patent Office and was before the Tenth Circuit. Laverty is obviously a practical man rather than a chemist, since he refers to the use of a pickling bath containing a hydrocarbon. Hydrocarbons are not soluble in a pickling bath, and don't do much good in a pickling bath; but on reading his specification one finds that the agent that he is interested in is tar sludge, it being a waste product of the oil refining process containing tar and oil and sulphuric acid. That appears at about line 35 of the first page. Now, it likewise appears from the line following that, (reading): "I preferably add the sludge to the acid generally about one part sludge to 15 parts acid by weight. This will give an excess of oil to the acid, the surplus oil being afterwards skimmed from the top of the bath."

Actually, that oil tar sludge contains a great many different organic chemical substances, and you will find, Your Honor, as we go along that many of the inhibiting agents proposed by other individuals are such industrial wastes as this tar sludge. If one consults the classical work on petroleum, Das Erdoel, which means petroleum, by Engler, one will find that oil contains, among other things,

nitrogen ring bases, and later on patents will be referred to which mention nitrogen ring bases as actually preferred agents to be used in pickling baths.

It will be found that there is a reference to tar sludge, I think, in the patent in suit.

The Court: Here is the reference in the patent in suit, (Reading): "Such as sludge acid from oil refining and residues from acid sulphite paper manufacture, etc." A. That is right, Your Honor. Well, now, with such agents, there is no guaranty that one of them will be as strong as another, or will contain the same ingredients as another, since they are industrial waste products.

The Court: But what you do say is that both patents refer to that ingredient or those ingredients? A. That is right.

The Court: Is there any difference between the two? They use different words there. What is your interpretation? A. I do not see how you can find any difference. He says that tar sludge is the material I preferably use. That is Laverty. On account of its cheapness, it being a waste product of oil refining process. I think that is the same product to which Grebe and Sanford refer. They refer to it as various by-products of industrial processes, such as sludge acid from oil refining. Now, obviously, a waste product of oil refining, being a tar sludge, is the same thing.

Mr. Owen: In the Gravell patent where it refers to nitrogen ring compounds, would that be the same thing as Laverty referred to? A. Not all nitrogen ring compounds, although ring compounds may be contained in the tar sludge. Line 50 of page 1, Gravell patent, he refers to—

Mr. Owen (interposing): That is the same thing Laverty refers to? A. Yes, all these inventors have been in the habit of reciting materials from the previous patent literature as examples of the things they mean. Grebe and Sanford and Gravell were no exception to the general rule. The object of that Laverty invention was to provide a pickling bath, among other things, in the use of which a scale or oxide is removed from the metal without appre-

ciably attacking the surface of the metal. He repeats that phraseology almost exactly in the second column of page 1, where the says: "the surface of the metal is not attacked by the acid in the bath to any appreciable extent during the time required to remove the scale from the metal." Actually, of course, crude materials of this kind are unable to afford awfully good protection unless they are used in very large quantities.

Mr. Lyon: But to be compared in what way to the object of Grebe and Sanford? A. The object as expressed there is identical with the object of Grebe and Sanford.

Q. You will have to tell us what it is. A. Namely, to remove something. We all know it isn't exactly the same as Grebe and Sanford in that in this case Laverty is interested in removing scale, as I talked about this morning, from the metal without appreciably attacking the surface of the metal. Grebe and Sanford are concerned with getting the acid down into the well without appreciably attacking the metal. The problem is similar but not identical.

Well then, the next patent is the one to Beneker, No. 914,916.

Mr. Babcock: Your Honor, that patent wasn't cited by the Patent Office but it was considered in the Williams Bros. case.

Mr. Owen: I have a note it was cited in the Grebe file wrapper.

Mr. Babcock: I may be mistaken.

A. The only thing I failed to say about the Laverty patent was he says "Other than sulfuric acid may be used and materials other than oils containing hydrocarbon"—in other words, he means any acid. Beneker disclosed the use of arsenic acid in a wire and metal cleaning bath. I mention it particularly because arsenic is a preferred agent of the Grebe and Sanford patent in suit, and also because Beneker gives a description here which might be helpful to Your Honor, of pickling in which he says before all the scale has been loosened the exposed metal has been vigor-

ously attacked by the acid. Beneker patent about line 20 of page 1. That is a description of the ill-effect that he is trying to avoid. He mentions around line 13 that the pickling bath may consist of sulphuric or hydrochloric acid. He mentions the use of arsenic in quantities as low as 5/1000% of arsenious oxide and he seems to prefer to use from .001 to .005% of arsenious oxide, line 65, page 1, where he says: "preferably from .001% to .005% of a compound of arsenic, as, for instance, arsenious oxide." I call Your Honor's attention to the fact those are very much smaller quantities of arsenic than are referred to in the patent in suit which refers to quantities in the neighborhood of from 1 to 5%. The reason for that is very large amounts of arsenic completely spoil the pickling operation. They coat the metal with an undesirable coating. They prevent the removal of scale from the irregularities of the surface and otherwise affect the desirable operation. That is a problem which does not exist when the acid may act upon a surface which does not necessarily have to be clean and beautiful after the operation, as in the Gravell or the Grebe-Sanford processes.

Q. Let's go to the next patent. A. All right, the Holmes patent No. 1470225. This patent is on the application of aldehydes as inhibitors. Aldehydes are not mentioned in the Grebe-Sanford patent, although I think they are mentioned in the Gravell patent. The principal matter of interest in the Holmes patent is that this is one of the early examples of the use of inhibitors for another purpose than merely pickling heat scale off of steel. At line 10 of page 1 Holmes states: "This invention is particularly applicable for the pickling of iron or steel wire or sheets in mill practice, but is also useful in many other ways, such as for cleaning or freeing iron or steel in any form from rust or oxides, or for removing scale such as boiler scale or the like from sheets or tubes."

Now, the meaning of that boiler scale is a deposit that is left by the evaporation of water in the boiler, and it consists usually of calcium and magnesium salts, and often is

not very far in composition from the composition of rock found in oil wells, or of common limestone. Therefore, the problem of freeing the boiler from boiler scale, or the boiler tubes of the boiler from boiler scale is very analogous to the problem of the patent in suit. You want to dissolve some type of limestone-like formation by means of acid which has to be transported in steel. In this case, one wants to remove the undesirable encrustation from the steel boiler without harming the boiler, and it is that particular analogous application for which I think this patent is most interesting.

Q. In either case, you want the acid to act on the lime material and yet the acid contains some inhibitor so that the acid will not eat or dissolve the iron? A. That is correct. And Holmes states that examples of suitable acids are sulphuric, hydrochloric, phosphoric and even acetic, although these weaker acids would probably not prove effective, that is, acetic and so forth. I was reading from line 60, page 1.

Q. All right. Let's go to the next patent. A. Next is the Gravell patent to which reference has just been had, and I don't think we need to go any further than that.

The Court: That is the defendant's patent in suit? A. Yes, sir.

Mr. Babcock: This patent was considered in the Patent Office and also by the Tenth Circuit.

A. The next is the Fischer and Stegemeyer patent, 1,736,282.

Mr. Babcock: That was considered both in the Patent Office and the Tenth Circuit? A. The interest of this patent is merely in disclosing still another class of inhibiting agents, namely, the reagents resulting from sulfonating mineral oil. As a matter of fact, the agents to which this patent refers are agents which are produced in the refining of very highly refined white oil, medicinal oil, and they are described by the patentees on page 1, at lines 61 and 62, as (Reading): "The sulfonic reagents resulting from this refining treatment are of very high molecular weight,

usually between 200 and 500, and are classified for convenience by their various characteristics of chemical behavior, such as their solubilities, etc. * * *

"Generally speaking, the bodies fall into two classes those which are oil-soluble in the presence of water, and those which are oil-insoluble in the presence of water."

And Fischer and Stegemeyer want to use the water-soluble members of this class as inhibitors in the pickling in an ordinary pickling operation.

Q. Now, does anything of the Grebe and Sanford patent correspond to those sulphonic reagents of Fischer and Stegemeyer? A. It is very probable that the sludge acid from oil refining of Grebe and Sanford, as well as the sludge acid of Laverty, contains some of the same compounds that are disclosed here by Fischer and Stegemeyer.

Q. Just exactly what sludge acid you would have would depend upon what you were treating with your sulphuric acid, wouldn't it, what oil, you were treating? A. It would.

Q. These fellows were treating a particular mineral oil? A. Yes.

Q. A medicinal oil, and the patent in suit of Grebe and Sanford does not say what they were treating; they just included all sludge acids, isn't that right? A. Yes.

Q. All right. Let us turn to the next patent. A. The next is the Rhodes patent, to which I have previously referred, No. 1,746,677.

Mr. Babcock: This Rhodes patent was not considered by the Patent Office, but was cited in the answer in the Williams Brothers case.

A. The Rhodes patent is of importance for two reasons. The class of inhibitors which Rhodes discloses are acridines, the formulas of a number of which appear in the first column of the second page of the patent. Acridine and derivatives thereof are mentioned at the top of the first column of the second page of the Grebe and Sanford patent. The second reason, and more important reason, for including Rhodes, is that Rhodes has given a fairly good exposi-

tion of the use and purpose of inhibitors. I should like to read first from the beginning of the Rhodes patent. (Reading): "The invention relates to inhibitors or restrainers useful in chemical and electrochemical processes for preventing or retarding the evolution of hydrogen at the surfaces of metals immersed in the solution or for otherwise preventing or retarding the chemical action of acids on metals."

That points out an interesting fact, that steel and the ordinary acid corrodable metals always corrode with the evolution of hydrogen in strong acid solutions, and anything which will prevent or retard the evolution of hydrogen at the surfaces will serve to prevent or retard corrosion. I wish to also call attention now to line 43 of the first column on page 1, where Rhodes says, after having described the use of his inhibiting agent in pickling, and so forth, (reading): "Another use of the process is in the removing of the metal oxide or carbonate forming on copper or other non-ferrous materials. Another advantageous use is in eliminating the scale forming in pipes and in the tubes of automobile radiators which often seriously interferes with the proper flow and circulation of the fluid through the radiator."

Now, that is another use which I consider highly analogous to the process of the patent in suit, namely, that you are to dissolve calcareous deposits formed by deposition from water on metal surfaces. In column 2, of page 1, at line 65, the patent reads (reading): "In its broader aspects, my invention contemplates the use of the inhibiting agents hereinafter more fully described in connection with any chemical or electro-chemical solution or reagent which under normal conditions of operation will evolve hydrogen at the surface of a metal immersed therein. In other words, my invention provides a means for causing desired chemical or electro-chemical reactions to take place and without substantially decreasing the rate of said reactions causing an inhibiting action retarding or actually preventing the evolution of hydrogen which would normally

take place without the presence of the inhibiting agents."

I think that might be written a little more clearly to say that he wishes to stop all processes which cause the evolution of hydrogen from an acid solution without stopping those processes which do not evolve hydrogen from solution.

The Court: Is there a definition in chemistry of agent and also reagent, so I can have that? A. Well, an agent isn't strictly speaking a chemical term at all. An agent is just a general term which means any person or thing which performs a function which is desired. A reagent is a substance which enters into a reaction, obviously with some other substance or substances.

The Court: Substance or what? A. Enters into a chemical reaction. Anything which enters chemical action with anything else is a reagent.

The Court: Hydrochloric acid and this limestone? A. They are both reagents. Hydrochloric acid and steel both the steel and acid are reagents.

Q. (By Mr. Lyon): You have said this Rhodes patent specifies the use of acridines. Compare that with the third reagent or agent specified at the first line on page 2 of the Grebe-Sanford patent. A. "* * * acridine and derivatives thereof," which appears in the first and second lines of page 2 of the patent in suit, Grebe and Sanford patent, describes the materials that Rhodes here refers to.

Q. So both Rhodes and Grebe and Sanford, so far as acridines are concerned, call for the same inhibitors? A. Yes, sir. The next Rhodes patent, No. 1,746,676, I will not refer to in any detail. It recites certain other acridine derivatives.

Q. Otherwise the disclosure has the same effect as the preceding Rhodes patent? A. It has. In fact, it is almost verbatim the same as the other one except for the actual agents therein disclosed.

The next patent to Vignos, No. 1,750,651.

Mr. Babcock: It was cited in the Patent Office but it wasn't considered by the Tenth Circuit.

A. The Vignos patent is cited for two reasons; in the first place, the preferred agents of Vignos are sulphonated mercaptans. Now, mercaptans, without reference to sulphonation, are referred to in the Grebe and Sanford patent on line 3 of page 2, such as mercaptans, it says: "organic sulphur compounds, such as mercaptans." These compounds of Vignos are still mercaptans. They are sulphonated mercaptans, he says, and for that reason I mention them. Vignos also recognizes the usefulness of his inhibitors, in quoting from line 21 of the first page: "The removal of deposits collecting within a water or steam circulating or distributing system, and also for removing scale such as boiler scale and the like from sheets and tubes." And Vignos also recognizes that these inhibitors may be added to the acid transported in an acid tank car to prevent corrosion of the car by the acid and can likewise be used to diminish excessive corrosion by water in systems employing mine waters, which is getting pretty close to what you are trying to do in the patent in suit.

Q. I think if you just tell the court what inhibitors these patents called for, as you come to them, and for what purpose, that would be all that you would have to testify to about them, because they can always be read, and I think those are the pertinent things that the court is interested in. A. The Harrison patent, 1,766,902, relates to an inhibitor from the 1-2 Dianimo ethane. It mentions a number of derivatives, and it is used for pickling operations, and it says on line 7 that it is also useful for cleansing tubes from scale by pickling and for removing the scale and corrosion products that accumulate in water pipes, and it may be used in any case where iron or steel is to be freed from rust or oxides, or wherever it is necessary to treat iron or steel with acids and solution of the metal is undesirable. It says that it is useful in any case in which it is necessary or desirable to use acidic materials in contact with iron or steel.

The next patent is Corson and Lawrence, 1,773,953, and refers to a certain special type of sulphonation prod-

ucts of mineral oils, which contain in the neighborhood of 10 per cent or more total sulphur as inhibitors. They are ichthyol-like materials. They are in the class of organic sulphur compounds, but not very closely related to any of the other materials mentioned in the patent in suit. It is also stated that they are useful in removing undesirable encrustations and corrosion products associated with metals which are submitted to acid treatments, and it says on line 69: "There are, however, many other processes in which acids could be used to dissolve rust or encrustations upon the metals." It mentions the use of the materials in hydrochloric acid.

The next patent to Lawrence, 1,780,594, refers to the type of inhibitors known as the thioglycollic acids. Its derivatives contain the radical $COOH\text{-}CH_2\text{-}S$. And once more it refers to the general use of inhibitors to remove either oxides, rusts, scales, salts or other undesirable encrustations and corrosion products.

The Court: One would think many of these are almost identical. I suppose, if you come to read them, there is some theory on which they claim an improvement on the previous one.

Mr. Lyon: We are really putting them in here, Your Honor, just to show that these various agents, that all the inhibitors that are mentioned in the Grebe-Sanford patent and many others are all known to be inhibitors, and then to show that as to certain of these patents that they were known generally for uses wherever the acid contacted the metal, and, specifically, many of them describe where the acid is acting on a lime material. They don't really add very much to the Gravell patent that our counter-claim is on. I think that is really the most pertinent prior art patent for Your Honor to consider.

The Witness: This is another one of a large class of organic sulphur compounds.

The next patent to Lawrence adds no new ideas to the ones that we have just described and disclosed. And it claims to use as inhibitors compounds which are known as mustard oils, the isothiocyanates.

The next patent to Calcott, 1,785,513, is of interest because it mentions specifically the use of mercaptans, which are of the class of agents described in the patent in suit, and which have been mentioned here as having possibly been used by the plaintiff. The patent specifies generally the treatment of metals with acids, and this is on line 10—"For the purpose of inhibiting this solvent action on the free metal, certain types of substances have been added." And it goes on to say that these mercaptans are particularly effective.

The patent to Burke, No. 1,789,805, patents the use of alpha amino acid, and particularly substances derived by hydrolizing animal proteins which include the particular albumenoid protein, keratin. It is interesting only because it is another, still another of the large class of inhibitors which, however, can be related to a much earlier inhibitor that is mentioned in the art, namely, gelatin, since gelatin is one of the proteins which is hydrolized in hydrochloric acid to give you certain amino acid. In the second column of page 1, at line 64, a paragraph begins which speaks of the transportation or storage of acid solutions in metal containers. This patent, of course, was filed in 1929; it was some years after the Gravell patent had issued.

Nextly, the patent to Corson, No. 1,809,621, mentions a type of chemical inhibitor not heretofore mentioned, namely, the thiuram compounds, notably the thiuram sulphides, and it makes quite a point of the removal of scale or other acid soluble deposits from metallic articles.

Now, I think that closes all of the patents which refer specifically to inhibitors.

Mr. Lyon: We have a stipulation which I would like to read in evidence in this case, which is page 61 of the deposition of Mr. Boundy, taken in Midland, Michigan, on July 25, 1940, which reads as follows:

"It is hereby stipulated by and between the parties to this litigation that in all the work done by the Dow Chemical Company, or anyone in its employ, or on its behalf, prior to February, 1932, no inhibitor of any kind, nature

or description was used in connection with the acid used in the treatment of brine wells, and the reports and records of the Dow Chemical Company so show.

"Mr. Owen: The proposed stipulation is accepted."

Mr. Lyon: Now, Mr. Douty, you have called attention to these prior patents. I would like to have you tell us as a matter of your own knowledge, and to what extent inhibitors were being used with hydrochloric acid prior to more than two years before the application for the Grebe and Sanford patent in suit, what use was being made of them commercially, and for what purposes, and to what extent, to your knowledge? A. Prior to approximately 1930, in other words, some time in 1930—well, I know that at that time we were selling inhibitor to some people who pickled with hydrochloric acid. We were selling inhibitor to others who were removing various types of calcareous deposits from equipment of one kind or another, with hydrochloric acid. I am not going to be able to tell you to what extent, because I do not know relative to our whole business how much of it went into these particular uses that I am describing, but I know that it was used—

Q. (Interposing): You know that you were selling those materials for commercial use? A. Yes. Now, I also know that on at least one occasion, and I do not know how many more, the acid was sold to be used for some purposes in connection with an oil well, down an oil well.

Q. Who was that sold to? A. Well, I have seen the records of the Gypsy Oil Company sales where they used acid, as I have been told later, for cleaning out—or freeing tools or removing gyp from the pipe. Prior to 1930, or September, 1930, I can't think of any other uses in connection with hydrochloric acid at the moment, and I don't know the extent of the use in any case.

Q Were others selling inhibitors? A. Yes.

Q. Your own company was selling inhibitors, was it not? A. It was.

Q. Beginning when, as far as your knowledge is concerned? A. As early as December, 1923, and continuously thereafter.

Q. And did you have competitors in that business? A. Yes; we have had a number of competitors. The Grasselli Chemical Company sold inhibitors. I don't know exactly when they began to sell. But I know they have been doing it for a number of years.

Q. Well, they were doing it before 1930? A. I am sure they were. How much earlier, I don't know. The Barrett Company were selling inhibitors pretty far back. Then—let me see, I don't remember just when William M. Parkin began to sell. William M. Parkin of Pittsburgh. And a fellow named Addison Hoffman of Pittsburgh. And I think Parkin used to sell things for him. We have had altogether some thirty or forty competitors. Some of them are still in existence. Most of them aren't.

Q. Then you can state that this knowledge of the use of inhibitors was not confined to the patent art, but was actually commercially practiced prior to 1930? A. Oh, yes.

Q. On a wide scale, for various purposes, to protect the metals from the corrosive action of the acid? A. Oh, I am sure of that. I know that in February of 1930—on January the 3rd—let's see, it says here—I think that must be a mistake. It says Friday, January 3rd, 1929, I was supposed to have delivered a paper on the use of inhibitors in the pickling of steel before the Philadelphia Branch of the American Electroplaters Society. Now, whether that was 1929 or 1930, I can't say now, because this is the February, 1930, issue of the Quaker City Platers Reminder from which I am reading. Immediately under the title of my article it says "Friday, January 3rd, 1929." I can't say which year that was. But, in any case, at that time I read a paper on inhibitors in which I told something of the art, and apparently it was not particularly mystifying to the platers who were at that meeting.

Q. Was that paper printed and published? A. Yes. This is a copy of it.

Mr. Lyon: I will ask that that be marked DX-295.

(The copy was thereupon marked DX-295.)

Q. (By Mr. Lyon): You have referred to the sales

to the Gypsy Oil Company. We already have in evidence these exhibits at page 459, 461 and 463 in the appellate record in the Williams Brothers case. Are those photostatic copies of the records you had in mind? A. They are.

Mr. Lyon: These are the orders from the Gypsy Oil Company, Your Honor, to Mr. Douty's company. For the Rodine No. 2 which Dr. Wescott recommended be used in the treatment down in Oklahoma. I think those are already in evidence. If they are not, I will declare them so now, with Your Honor's permission.

The Court: All right.

Mr. Lyon: Mr. Douty, in preparing that article or address of yours which we have just referred to a few moments ago you made quite a study of the history of inhibitors, did you not, and where they were first known and the extent to which they were known in past history? A. I read what literature was available on the subject.

Q. Now, there has been some suggestion here about what was known about inhibitors at the time of Frasch. The work Frasch was doing, Frasch applied for a patent on June 27th, 1895. Tell us what was known about inhibitors at that time, what was known—or might have been known in scientific literature and whether they were in use or commercially known at that time? A. In that paper that has just been marked as an exhibit, Your Honor, you will find that the earliest reference to the commercial use of inhibitors, as they are called today, that I was able to find, was in the early twentieth century, starting somewhere around 1907 or 1908. To be sure, I found as early as 1845 a paper by a Frenchman by the name of Millon in the Comptes Rendus, on a memoir upon the action or water on metals in the presence of acid and salts. That, indeed, did mention that certain metals had either accelerating or retarding effects upon the rate of solution of metals, different metals, in acid. But, it was a purely scientific observation which, as far as I know, no technical use had been made until 1896; I think I rechecked that date, and that was the date when this fellow Meurice published in the

proceedings of the Belgian Chemical Society an article in which he described the effects that he had obtained with arsenic in the pickling of wire in his mills. Now, that is the earliest article that I was able to find which mentioned any practical use of any inhibitor. That use was in a Belgian wire mill, as far as I was able to find out.

Q. Well, as far as your search revealed, could you find any reference to the commercial use of inhibitors or knowledge of inhibitors in the United States back at the time of Frasch's work in June, 1895? A. No, none at all.

Q. And do you believe your search was a thorough search? A. I think it was a fairly complete search. I think it was in 1901, or somewhere along there, that an investigation of the effect of arsenic was made by Burgess, but I may be mistaken in that date. It was certainly in the 1900's, and even then there was no commercial use of it so far as I know. Beneker's patent came out in 1909, in March, 1909. It was applied for not over a year or so earlier, and to be sure I had heard from old picklers by word of mouth rumors of the addition of certain things like mouldy flour and things of that kind to produce a foam on a pickle bath further back, but they could not be sure of the date, and when I asked them it was in the 1920's, and how far back that experience really went it was impossible to say. I could find nothing written on the subject earlier than the twentieth century.

Q. You couldn't find any record of the sale of inhibitors in this country or the existence on the market of inhibitors prior to what date? A. Well, as a matter of fact, I don't think that there was a commercial inhibitor sold in this country before 1920.

Q. And who made the first sale, as far as your knowledge goes? A. I am not sure but what the material was known as Picklette, and it was a solution of coal tar bases extracted from anthracine oil, and I wouldn't be surprised if it had been put on sale by the American agents of an English firm.

Q. About 1920? A. Yes.

Mr. Lyon: While we are about it, I don't think this Williams Bros. record has been given a number. Only parts of it are in evidence; the record shows which part, but under the practice it should be offered. I will ask that it be stamped DX-297.

(Whereupon Exhibit DX-297 was marked by the reporter.)

Mr. Lyon: Before I ask you to give your conclusions from the corrosion curves that Mr. Hathorn has produced, will you please tell the court what experience you have had in making corrosion tests and interpreting and understanding the results of corrosion tests, how long have you been doing it and to what extent, and to what extent you are familiar with the procedure and interpreting the results? A. Starting in 1923, in the late summer, I began to make corrosion tests, particularly tests on the corrosion of metals, particularly steel, with acids, very extensively. And I continued making hundreds and thousands of such tests by various techniques, some of which I developed myself, up to and including the present day. For up to the period up to about 1930, I would say there was scarcely a working day where I did not make half a dozen such tests by one means or another, one method or another. Some of the earliest work I did on corrosion by acid had for its object the determination of conditions under which metal surfaces could be made—brought into such a condition as to make corrosion tests more or less uniform and reproducible.

I think I will state the conclusion first, that I never found such conditions. I have tried every conceivable method of cleaning and pre-treating and it almost works down to the fact that you have got to get—to reduce the thing down to a statistical average before you can believe very much of any corrosion series. Among other things that I thought might be very uniform for the purpose of testing for corrosion was piano wire. I thought music wire from one roll of very fine music wire would be about as uniform a specimen as I could possibly get. Well, I found that any results you got from such a piece of music wire,

within any reasonable period of time, failed to check each other by fifty per cent or more, repeatedly. And it has been my experience throughout that only by the very greatest precautions as to reproducibility can you get results that are at all close together, particularly when you are trying to measure interference with normal corrosion rates by the presence of accidental or intentional impurities. I won't go into it any further, except to say that it is a subject with which I am quite familiar.

Q. In connection with your work in preparation for this case, I understand you were able actually to devote only a limited amount of time to your preparation, is that correct? A. Very little time.

Q. You didn't have time to stop your other work and run a six months' or a year's series of tests to prepare for this case, is that right? A. Nothing like that.

Q. Well, did you have time to make any laboratory tests? A. Yes, I made some laboratory tests whose object was to find out whether the Menaul process under the best conditions could actually be operative. I recorded those tests and the results thereof in a laboratory notebook which I produce. (Producing book.) As a matter of fact, this particular book has a variety of things in it. It is just a loose-leaf notebook, but every single bit of data that I have I will now produce (handing sheets to Mr. Lyon). That is all. The rest of the notebook is filled with notes taken at this trial.

Mr. Lyon: These sheets seem to be numbered or lettered "A" to "W," consecutively, and then there are six more sheets. That will give anybody wanting to count them information as to whether they are all here or not. I will ask that these be received and marked DX-299.

(The sheets referred to were marked DX-299.)

Q. (By Mr. Lyon): These notes, or these writings, constituting DX-299, are all in your own handwriting, are they? A. Yes, sir. They contain my conclusions, any conclusions that I reached as a result of those tests. I ran four series of tests here—

Q. (Interposing): Will you just explain to the court what the tests were and what conclusions you drew from them? Of course, the exhibit itself is in evidence, but just give the court a summary, if you will, please. A. The first three tests were intended to evaluate the effect of the contact of a piece of steel with lead in protecting it from attack by 15 per cent hydrochloric acid, and they were made under various conditions of contact and time, so that I was trying to isolate, if any, the effect that the dissolved lead chloride might have, and the effect that the electrical connection might have, and the fourth test, which repeated the first one, was made much later. These tests were performed in December of 1939, and then I did no further work except for several days in June of 1941 when I did the fourth test. That was the first time I ever heard about copper having anything to do with this case, so I made some tests involving the use of copper in proportions somewhat larger than had ever been found in any of the defendant's acids as reported to me. So that I have four tests here of a Menaul system, really, and variations of the Menaul system, in order to find out. Then I find in this notebook also a few measurements of the potential of lead versus steel in hydrochloric and sulphuric acids, which have not been transmitted to anybody else, but which I simply found in these notes.

Q. But they were made by you? A. All made by me. All this work was by me, helped by nobody. All on a laboratory scale.

Q. Now, will you just give us what your findings and conclusions were as they are expressed in the exhibit? A. At the conclusion of my first test I had reached the following conclusions:

1. Lead chloride is a slight inhibitor of the corrosion of steel by hydrochloric acid of the strength used by oil well treaters.

2. Connecting the steel to a piece of lead protects the steel far more perfectly than does adding lead chloride to the acid.

3. In acid containing lead chloride the protection afforded the steel by connecting it to a piece of lead is not only not improved but is actually impaired by the presence of the lead chloride.

The Court: I think I understand that, but the two conclusions seem inconsistent. A. They would, Your Honor.

The Court: In other words, at first I had the idea the lead connected to the iron was better than the lead flowing loose in the hydrochloric acid? A. That is right.

The Court: Then I get down to the second one and it is just the reverse of that, isn't it? A. I think Your Honor will understand the conclusions better when I describe the experiments. They are very simple and I think conclusive.

The Court: All right.

(Witness continuing): The fourth conclusion is—lead chloride dissolved in the acid does not produce a continuous, adherent film of lead on the steel.

5. Steel connected to metallic lead acquired in the acid an adherent, apparently continuous film of lead. Incidentally, I base that not upon any analysis of lead but based upon an actual difference in weight, which is considerable. In other words, a piece of steel was weighed at the beginning of an experiment and at the end of the experiment. In addition to that, the solution is analyzed for iron at the beginning and end of the experiment. Now, the loss in weight of the steel should be the same as the increase in iron in the solution. But it turns out that when the steel is connected to lead, the loss in weight of the piece of steel is considerably less than the amount of iron found in the solution. Now, that means that the steel must have lost some weight of iron and gained some weight of something else. Otherwise, it would have lost as much weight as the iron I found in the solution.

The Court: Iron has to get away somewhere. A. It did go away and yet the steel didn't lose that much weight. So I was able to weigh that difference in a number of experiments and conclude the steel had from 3 to 5 millionths of an inch of lead on it at the end of the experiments.

Mr. Lyon: You were reviewing your laboratory work, Exhibit No. 299, and I asked you to make a summary of the work and read the conclusions as you arrived at them and recorded them in this exhibit, and I think you had just finished reading the conclusions on your first three experiments, which were, as I understand it, experiments you did to determine the effect of bonding steel to lead. A. Mr. Lyon's question was not exactly correct. I had only read the conclusions which occurred at the end of the first experiment that I had run. I then ran a second experiment, and at the end of the second experiment I had not arrived at any further conclusions in quite the same form. I ran still a third experiment, and after I had finished the three experiments I had confirmed some more ideas that I had had. I think before discussing the conclusions, I had better state briefly what tests I made and what they were. They were entirely laboratory experiments. The object was to find out the rate of solution of iron from ordinary tank steel in plain acid, where the steel panels alone were in the acid. In plain acid, where the steel panels were resting in contact with lead strips, and in plain acid where the steel panels were in the same beaker with, but not in contact with the lead, and then a second series of three in which the acid was initially saturated with lead chloride. That is, I had put in as much lead chloride as the acid would take up, and then the steel panels, certain steel panels were placed in a beaker full of that acid alone and another beaker containing a lead strip and in contact with a lead strip, and in a third beaker—in the same beaker, with a lead strip but not in contact with it. The way that was done, I cut three inch squares of tank steel of 14-gauge, which is about 78 thousandths of an inch thick, and lead strips about 1½ inches by 10 inches by ⅛th inch were bent into a "U" shape about three inches across the top of the "U" and the arms about three and a half inches long.

In those experiments where the steel was in the beakers alone, I chose beakers of 600 milliliters capacity in which the three-inch squares of steel would stand on the

bottom not quite erect, because they would rest against the curved sides of the beakers. In those experiments where the lead strip was to be in contact with the steel, the lead "U" was first placed in the beaker with the arms upward. The steel was then placed resting upon the "U" on the bottom of the beaker and leaning over to one side, and one arm of the "U" was then bent over so as to make contact with the steel square at the top as well as at the bottom, so that the steel square rested on the lead at the bottom and also rested against the lead at the top. Just to complete the record, the experiments were run at 90 degrees Fahrenheit, the beakers were placed in a thermostated air bath and the temperature was kept constant to within four-tenths degrees. The acid used was very close to 15 per cent acid. I record it as 4.37 normal. I started with chemically pure hydrochloric acid. The panels as they came to me were cut out of a piece of tank plate and had their original scale on them. Before starting the tests they were pickled free of scale in acid of approximately the same strength as was used in the test, which took three minutes. They were then washed with water, with dilute tri-sodium phosphate solution, again with water, and then with alcohol, dried and weighed on a chemical balance. The lead strip was scraped clean with steel wool and dipped for one minute into one to one hydrochloric acid, washed in water, dried with alcohol before the test.

In this first test each type of test was run in duplicate and the panels were allowed to remain in the acid under the conditions specified for 15 hours. The panels were then again washed under the tap, scrubbed with a bristle brush under the tap, and washed with dilute alkali, again with water, then with alcohol, dried and reweighed. At the conclusion of the test, the solutions were all analyzed for iron by titration and the loss in weight of the panels was compared with the amount of iron found in the solutions at the end. As an example of the type of results that were obtained, I have expressed the losses in weight as a per cent of the loss, a per cent of the original weight of the

panel, because the panels, although they were cut fairly accurately to 3″ square weren't exactly of the same size, and therefore since almost the entire area consisted of the large flat sides, the sheet being all of the same thickness, the weight of the panel was closely proportional to its area and therefore the best way to express the results was as loss in weight as a per cent of the original weight. The results are these: When the steel only was exposed to the plain acid the panels lost on the average 2.954 grams—I mean per cent of their weight.

The Court: That isn't grams? A. That isn't grams. That is per cent of the original weight. In other words, they lost about 3% of their original weight. When the steel was touching the lead the panels lost an average of .0172% of their original weight.

The Court: What is that? A. .0172%. In other words, something around 1/200 of the loss in the first case. I want to call to your attention, Your Honor, those were not the actual losses in weight. Those were the amount of iron found in the solution at the end. The amount of iron dissolved expressed as per cent of the original weight.

The Court: Well, is that .0172%—A. (Interposing): That is per cent of the original weight of the panel, Your Honor.

The Court: Before this experiment? A. Yes, sir. In the third case, where the steel was in the same beaker but wasn't touching the lead, the average loss was 1.934% of the original weight of the panel. Now, in the second series of experiments where the acid used was originally saturated with lead chloride, when the steel alone—

The Court (interrupting): Now, let's see. This is the one where you started out. A. This series of 3 tests which I have labeled D, E and F, were all run with acid which was originally initially completely saturated with lead chloride.

The Court: In what per cent? A. It was still the same acid, Your Honor, in strength—15% acid, but the lead chloride at 90° F. in that acid, lead chloride is soluble to

the extent of approximately 10 grams per liter, somewhere around that order. In other words, around 1%.

The Court: The second one is going to be saturated in lead to start in with? A. Yes, sir. That is about one per cent of the weight of the solution. The panel where the steel only was present in the beaker lost 1.870% of its weight. The iron dissolved was 1.870% of the weight of the panel. Where the steel was touching the lead, the loss of iron was .243%. I have it here .2426, but I don't think that number means anything beyond about two significant figures, anyway, if that much.

Then the third experiment, where the steel was in the same beaker but not touching the lead, the panel lost 1.409% of its weight. Now those are the averages of two experiments carried out to an absurd degree of accuracy but they are simply what I found. Now, you will notice the significant thing about that test is that comparing experiments A and B in which plain acid the steel was either touching lead or not touching lead, we have only about somewhere 1/60 times as much attack when the steel touches the lead; in the second case where the bath was originally saturated with lead chloride we have somewhere around 1/9 as much attack, relatively speaking. In other words, as far as that particular experiment goes, the relative protection was far less when the lead chloride was present.

Now, an interesting thing about these experiments was this—when the panels were observed after the operation it was noticed that those panels which had been in plain acid or had been in contact with acid saturated with lead chloride but which had not been in contact with metallic pieces of lead, they were generally etched, they were dark in appearance, had a loose film of carbon-like smut which easily washed off under the water tap with a soft brush. The panels were slightly rough to the feel, to the touch. The panels which had been in contact with the metallic lead during the immersion were a clean gray in color, they didn't have any smut, and they felt greasy to the touch.

Without going into the details, after making a few experiments, and then analyzing the accuracy with which my analyses for iron were made, I found that I could not possibly have made an error in my iron analyses that would have been greater than about two per cent of the amount of iron determined; and for small amounts of iron, I could not have made an absolute error in the amount of iron determined greater than approximately a few milligrams at most. In comparing the actual losses in the weight of the panels with the amount of iron found in a solution, I find that in experiments, A, C, D, and F, the ones where the iron did not touch the lead, the quantities of iron dissolved compare with the loss in weight of the panel in every case, within about one per cent or less. However, in the case of the panels which have been touching the lead strip, it turned out that the iron dissolved exceeded the loss in weight of the panel by a considerable amount.

In the case of the panels in the second test, the average was approximately 95 milligrams; that is to say, that the panel must have gained weight in lead some 95 milligrams. In the case of experiment E, where the lead chloride was present, the average was about 160 milligrams. So that, computing that with the regular density of lead, that would mean that the panels were coated with approximately three to five millionths of an inch of lead.

The next experiments after these were in an attempt to find out why the protection in the presence of the dissolved lead chloride was not as good as it was in the absence of the dissolved lead chloride; and they lead to this conclusion in the second experiment, that is, the second experiments were carried out in approximately the same way as the first, except that I omitted the series in which there was lead in the beaker, but not touching the lead strip; and I left that experiment go on for a total of 96 hours, analyzing the solution at 24, 72 and 96 hours, and at the end weighing the pieces.

And I found that where lead chloride was absent from the solution to start with, gave protection, good protection

for the lead which lasted about twenty-four hours and began to break down before seventy-two hours. But I found that in the case of similar solutions in which the lead chloride—the solutions were originally saturated with lead chloride, that the latter failed to give very good protection for more than about twenty-four hours. Even at that time, protection was beginning to fail, and I ascribed that to the fact, which was easily observable, that the junction between the lead and the iron, which was formed merely by gravity, had been spoiled by a growth of lead chloride crystals and the lead had become insulated from the iron. And it didn't occur very much if at all in fifteen hours, but it occurred pretty completely in twenty-four.

So I then set up a third experiment in which, instead of using the system that I have described, I made a small hole in the top of the panel and I hammered the lead through with a hammer, through the hole on one side and bent the strip over on the other side, and hammered it down, kept upsetting the lead and hammering it until I had an exceedingly tight joint, and then bending some in a self-supporting piece which held up the strip in contact with the lead, and then ran the experiment again, for a total, in this case, of ninety-two and a half hours.

In that second case, I found protection, perfect protection was obtained in both solutions which had lead chloride in them to start with and those which did not; for a period of twenty-two and a half hours. Quite good protection was obtained for a period of sixty-eight hours. But that protection was beginning to fail before the end of ninety-two and a half hours, and that the assembly had—the steel assemblies had become loose with the lead so that the contacts were broken. And I was able to conclude from the over-all set up of the experiments the things that I read in the first place, and also that if you don't make a very, very excellent bond between lead and iron you are going to destroy your protection quite soon.

Every one of the experiments, however, indicated that the total iron dissolved was greater where the solution was

initially saturated with lead chloride, that is, for those cases where the steel was touching the lead and when it was not. And that persisted for all three of the experiments, particularly—for all three of the experiments.

The fourth experiment was carried out in exactly the same way as the first experiment described.

Mr. Owen: Have you given any figures on the third experiment? A. I haven't given any figures, Mr. Owen. I don't think reading the figures into the record is going to make the picture any clearer. I will give you the figures, and if you think you can—

Mr. Lyon (interposing): They are all in your exhibit? A. All in the report. I don't think reading them into the record adds anything to the picture. The fact is that bonding the iron to the lead gave very good protection. Not as good protection, quite, when there was lead chloride present. And that the protection would last as long as you could maintain the bond. And that the bond had a bad tendency to fail.

Now, my fourth experiment was made in June of 1941 whereas the other three were made in December of 1939. I made this in a considerable hurry, because that was the first time I had heard that copper was supposed to be a factor in this picture, and before I came out here to Bay City I wanted to know how this Menaul effect behaved in the presence of copper. So I set up the thing again exactly as I did in Test No. 1, except not having very much time I simply set up individual pieces, not even in duplicate, under exactly the same six conditions that I have described in the first experiment. The solutions I used were these: I used for the experiment first—for Experiments A, B and C, under the fourth test, plain C. P. acid. For Experiments D, E and F, I used C. P. acid to which had been added, as chlorides, 500 parts per million of lead, five parts per million of copper, and 500 parts per million of iron, which were quantities a little bit larger than the largest quantities reported by the plaintiff here for any of defendant's samples. And the net result of that experiment was to give me results which led to about the same conclusions.

That the protection afforded by the contact with the lead was to reduce the attack about 1/160th of its original value, whereas the dissolved metals reduced the attack to about half of its original value. And, the protection afforded by contact with the metallic lead was reduced to 1/50th of its original value instead of 1/160th of its original value in the presence of the dissolved metals, and the absolute amount of iron dissolved from the panel was .0175 grams in the case of the panel immersed in plain acid.

Mr. Owen: Is that grams or per cent? A. That is grams. If you want it in per cent, it was .02 per cent of the weight of the panel, and in the case of the second panel which was immersed in the acid containing the lead, copper and iron, the loss was .0287 grams or .03 per cent. The values are quite small, but curiously enough they accord very accurately with the other small values that I found in the other experiments which compare the loss in weight of the specimens which were in contact with lead when the acid was plain and when the acid originally contained dissolved lead chloride. That was all these experiments were designed to prove, and I think that they show, as far as these conditions go at least, the presence of lead chloride, all the way up to saturation, of lead chloride, copper chloride and iron chloride together in proportion somewhat greater than those specified as the maximum found in defendant's truck tank samples in no way assisted the action of the Menaul system, but actually were detrimental to it.

Q. Now, have you completed reading all your conclusions in Exhibit 299? A. Yes, sir.

Q. As to the actual values that you determined, that is to say the amount of losses, the amount of dissolved iron that you found as a result of these experiments were comparable at all, how do they compare with the values that are set forth in Dr. Bartell's reports as found by him? A. Well, of course my steel samples were not the same as his, nor were they prepared in the same way as his, and yet I would say in general my results accord very closely with Bartell's, where they are comparable.

The Court: You get it in percentages, the amount of the solution, taking the reaction in percentages of the weight of the mass of iron, as I understand it? A. Yes, I did that, Your Honor, because the pieces were not identically the same size, and that was the best way you could compare them. The percentage didn't have any reference to rate of attack, except simply to show you how much of that particular piece dissolved during the period of test.

The Court: But it does depend really, what we are really interested in is how much a given surface was attacked, isn't it? A. That is right, Your Honor. However, I gave you the thickness of those panels, Your Honor. They are about 78/1000ths of an inch thick, so if it loses three per cent you can see how much it would lose in thickness.

The Court: Yes.

Mr. Lyon: Now, have you examined Mr. Hathorn's curves, Exhibits 280 to 286, and are you prepared to tell us what they reveal and what significance they have? A. Yes, I have.

Q. First as to the effect on the corrosiveness of the acid in the Menaul tank, what do these curves show or establish in your opinion as to the function served by and the result obtained by the bonding of the lead plate to the steel of the tank? A. I think the curves show very definitely that the connected lead plate greatly reduces the rate of corrosion.

Q. Will you review upon the curves and point out wherein you find such a showing, or find your statement substantiated by the curves? A. Before I begin I want to say that in general I can draw I think five conclusions that have some merit from the experiments which were conducted on what are here referred to as hard steel tanks. As to the experiments conducted on soft steel tanks, I think I am able to draw only one conclusion that I would like to stand on, but we will start with the experiments conducted with these hard steel tanks, which it has been testified are made of the same metal out of which defendant constructs its transportation tanks. Now, by comparing curves 1, 2

and 3 of Figure 1, one arrives at a range over which all commercial acid seems to corrode this particular type of steel. In other words, there seems to be a uniformity of experiments—there seems to be a range within which one can expect two experiments to agree (indicating). If we then compare with those Nos. 4 and 5, in which the tank was connected to the lead plate, that again would be a range within which individual experiments may vary. But since the range seems to be fairly well outside the range of experiments 1, 2 and 3, we can conclude that the bonded lead plate has substantially reduced the amount of corrosion going on in the tank. Whenever I say "lead plate," I mean "bonded," unless I say "disconnected," because I now come to the second conclusion, and I wish before going on to the second conclusion to have Your Honor look at sheet 2, DX-281—I was previously referring to DX-280. Now, referring to DX-281,—we have only one result on this chart, namely curve No. 1, for commercial acid alone. We know from examining this exhibit that there will not be any irregularity in the amount of the attack of that commercial acid within a considerable range, but it is also clearly apparent that the installation of a bonded lead plate as shown in curves 3 and 4 certainly gives a marked reduction of corrosion. Now, referring to sheet No. 3, which is Exhibit 282-DX, we can once more compare curve No. 1, which refers to the rate of attack by commercial acid alone, with curves 3 and 4, which refer to the rate of attack by commercial acid in the tank which is furnished with a bonded lead plate.

(Indicating): Now, returning to Defendant's Exhibit 280, which is sheet 1, we find on referring to curves 4 and 5, which are for tanks containing bonded lead plates, when the bond is severed at the end of 24 hours, we know that there is a sharp rise in the rate of corrosion. That indicates with certainty that the lead plate was getting some protection electrically, not chemically, because the solution remaining in the tank at the end of the experiment is the same solution, and this change in slope certainly indicates

that electrical protection has a part in the protection. In those two instances, the tank was not cleaned after the disconnection, and therefore it might have been coated with lead or other factors may have—to which I will refer later —may have had a part in the fact that these new slopes are perhaps not identical with the mean of the slopes for commercial acid. However, one can see from these, in the case of curve 4, after the disconnection, one had a rate of corrosion greater than the rate of corrosion of the commercial acid in the plain tank.

Q. Before you go any further I think it would be helpful if you would answer one other question, because you have answered a question as to the effect of the bonded lead plate on the rate of corrosion in the acid in the tank; but so that you can also cover my second question while you are going through these curves, and not have to go through them again, I want to ask you my second question, and that is, what do these curves show or establish as to the corrosiveness of the tank acid after the bond is disconnected? In other words, disconnecting the bond by severing the connection in the tank, but removing the acid from the tank, as compared with the rate of corrosion of commercial acid? A. As I have said, within the limits of variation of the individual experiments, I would say that these curves establish that the acid which had been in the tank system containing the bonded lead tank (plate) was at the end of such a period essentially as corrosive as it was before it had been in that tank. That is likewise well shown in Sheet 2, Exhibit 281, by the change in slope of curves 3 and 4 after disconnection. It is to be noted that in the case of Curve No. 3 the acid was removed from the tank, the tank cleaned, and then put back in the tank again. It is seen that the slope of Curve 3 is not far different than the slope of commercial acid shown in Curve 1.

Q. What does that mean, Mr. Douty, with reference to the acid as it leaves the tank, it is going down the pipe in the well, assuming there is no electrical connection or effect from the tank to the pipe in the well? A. It means

that the acid which has been in the Menaul tank for as much as 24 hours is not essentially less corrosive than the acid I put in there in the first place. That once more appears from the comparison of curves No. 1 and 4 of sheet No. 3, Defendant's Exhibit 282, particularly on considering the latter half of curve 4 after the tank had been disconnected. Now, one would expect that at the end of 24 hours acid in such a system would have picked up about as much lead, iron, copper, or any other contaminant as it ever would in any of Defendant's practical tanks.

Now, another indication of the answer to the last question which I just gave, is shown on sheet 6, Defendant's Exhibit 285. In this case, which was run again on hard steel tank No. 1, we have some experiments made both with C. P. acid and with commercial acid to which have been added amounts of iron, lead and copper comparable to those found in the Zahn well, according to plaintiff's evidence. On comparing Curve No. 3, which is the curve for C. P. acid on that chart with Curves No. 1 and 2, which are respectively the curves for C. P. acid to which have been added iron, lead, and copper, or copper alone, we find no essential difference between the rates of corrosion in any of those cases. I would say that all of those curves might well be within the limits of variability of one experiment as shown by curves on previous charts. One curious anomaly is that in curve 4 where lead only has been added to the C. P. acid, the rate of corrosion appears to be considerably lower than curves No. 1 and 2, in which iron, lead and copper and copper alone, respectively, had been added.

Again, I think that the entire range covered by curves 1 to 4, inclusive, is simply a range of uncertainty in this type of testing, one that is to be expected in any type of corrosion testing on this scale. A comparison of curves 5 and 6, which are respectively curves for plain commercial acid and commercial acid containing the three dissolved metals in the proportions stated, shows no essential difference; both might equally have been separate experiments for plain acid or for any one of the acid series we have on

the chart. It is probably significant that the commercial acid in both cases, the curve for commercial acid in both cases, lies below those of the C. P. acid.

One more conclusion can be drawn from Chart No. 3, which is Defendant's Exhibit 282. It is to be noted that Curve 2 represents the rate of corrosion of an acid to which has been added one per cent arsenic trioxide. Am I right, one per cent?

Mr. Hathorn: Yes. A. And it will be noted that the rate of corrosion as shown by those curves is of the same order as the rates of corrosion for the experiments in which commercial acid was put into the tank having a bonded lead plate. Now, those are about all the conclusions that one can draw with certainty from the experiments made with the hard steel tanks, which seem decidedly less variable than those made with the soft steel tanks.

I don't know whether it is worth while to point to the experiments in the charts which represent the results on the soft steel tanks, which support the following conclusions: That the corrosion rates under apparently the same conditions are extremely variable. I think that has been already pretty well demonstrated. However, we might look at Curve 4, Sheet No. 4, rather, in Defendant's Exhibit 283, and compare curves 1 and 2. I should say in this particular example the variation between the rates for commercial acid alone, as represented by curves 1 and 2, is not markedly greater than the variation for the other type of steel. On curve sheet No. 5, Defendant's Exhibit 284, we find a rather tremendous variation between the rates of corrosion experienced by tanks of soft steel immersed, or, rather, containing commercial acid with the tank bonded to a lead plate, and that is rather more of a difference than ever appears on the hard steel tanks. We notice in this exhibit that the lead plate does definitely give some protection, and the same thing is visible in Sheet 4, Defendant's Exhibit 283.

The effects of Tergitol are to give throughout very curious and variable results, which can be seen by compar-

ing on Defendant's Exhibit 283, curves 4 and 6. And it is not entirely the only example. Now, we can find only one other significant--one conclusion that really—that is really valid for the soft steel tanks without any question, and that is that one per cent arsenic trioxide gave good protection in every case it was tried. You see that on sheet 4 and we see it again on sheet 5. Curve 8 on sheet 5 and curve 7 on sheet 4.

Q. Would these soft steel tanks, or these curves for those tests, permit a conclusion that the acid from the Menaul tank, after leaving the tank where the disconnection of the bond between the lead plate and the steel, was less corrosive than the acid which was introduced into the tank? A. No; I hardly think it would permit any such conclusion. I think if there is any conclusion at all, I would say that they were inconclusive on the point, on that point. I am speaking now of the experiments with the soft steel tank, that the normal rate of variation of corrosion for the original acid is so great that one cannot draw any conclusions from the slope of the curves after the disconnection of the lead plate. In fact, in most instances, they lie well within that range of variation.

Q. Would you consider that a criticism of Mr. Hathorn's work, or how does it compare with your own knowledge of what results can be obtained in measuring rates of corrosion on soft steel? A. The more corrodable the steel and the higher the rate of the corrosion, other things being equal, the less accurately the corrosion rate can actually be measured. In other words, for a slightly corrodable substance, metal, one is able to get more reproducible results than for a greatly corrodable substance.

Q. That is because the corrosion is going on in greater magnitude and, therefore, being a variable it increases, it magnifies the variation, the result you get, is that correct? A. That may be one reason; there are probably others that have to do with why metals corrode more rapidly and more slowly, such as the variability of composition within the mass. However, that is a fact that it is particularly

difficult to get check results when substances are present which deposit more or less irregularly upon surfaces during the corrosion.

Q. You are familiar with the report of Dr. Prutton in this case. In your opinion is his conclusion justified from that report in the tests reported by him as to the relative rate of corrosion of the Menaul acid after the bond had been disconnected or after the acid has left the system? A. No, I think that generally speaking Dr. Prutton's results simply fail to establish whether or not there was any electrical effect or not. They simply fail to establish it. In fact, the variation of Dr. Prutton's results among themselves have an order which would have permitted of a considerable degree of electrical protection without Dr. Prutton's method having been sufficiently refined to discover it.

Q. Well, do you think it is possible, based on your knowledge of trying to duplicate test results in measurements of the corrosiveness of hydrochloric acid on soft steel to conduct experiments of the kinds that have been attempted here on both sides which would, with any validity, establish or exclude the presence of an electrical effect assisting in protecting the pipe down the well if the connection is made between the pipe and the tank in the Menaul system? A. I am being asked whether something is possible. I do not like to say it is impossible, but I will say that no method that has been mentioned here, at least carried out as anyone has been able to carry it out here, with the best precautions, has been able to establish that one way or another at all.

Q. Now, you are experienced in this matter of electroplating and electrochemical effects as they affect corrosion, are you not? A. Yes, sir.

Q. That is your business? A. I am not—

Q. (Interposing): What is your view as to whether or not connecting the Menaul tank with the well pipe assists in protecting the pipe from corrosion; on theoretical considerations do you think that such protection should be

provided by that connection or not? A. I know that protection can be afforded a piece of steel by bonding the lead. I know that that protection can extend to a certain distance, and there are theoretical reasons for believing that it may extend to a great distance. I, therefore, see no reason why protection should not be afforded, at least to some extent, to the well pipe by the Menaul connection.

Q. Have we any method of determining, either theoretically or actually, quantitatively, how far that protection would extend? A. I would hesitate to say that we have a method available. I do not think there is a very easy way to find out.

Q. Well, do you know of any method? A. I do not.

CROSS EXAMINATION

By Mr. Owen:

Q. Will you refer to Table 2 on page F of the data sheets which are in evidence as DX-299 and compare your runs A-1 and A-2 with runs D-1 and D-2? A. Yes.

Q. First, state whether I am correct in my understanding that A-1 and A-2 represent blank runs using C. P. acid? A. That is correct.

Q. And D-1 and D-2 represent runs in which steel strips were placed in a lead chloride solution? A. That is right.

Q. What was the strength of that lead chloride solution? A. I don't know exactly—I know it was far stronger than any amount of lead mentioned in this case.

Q. Well, then, compare the average results of runs A-1 and A-2 with the average of D-1 and D-2, and state what you find to be the inhibition shown in the lead chloride runs as compared with the runs using C. P. hydrochloric acid. You used 15 per cent acid, I understand? A. I did. That has already been done, Mr. Owen, on page K of these results.

Q. What do you find to be that per cent? A. I find that if the attack in experiments A as compared with the

attack in experiments D—in experiments D I get about 63 per cent, 62.9 is the figure I have here, 63 per cent as much metal is dissolved in experiment D as in experiment A.

Q. Translating that into terms of inhibition, what would be the inhibition shown in the lead chloride solutions over that of the blanks? A. I presume that the number that Mr. Owen wants is obtained by subtracting 63 per cent from 100 per cent. I can do that, or anybody else can perform that arithmetic.

The Court: You got 63 per cent of what? A. Actually, Your Honor, I found that a certain amount of iron was dissolved in experiment A and a certain amount of iron was dissolved in experiment D, and the amount of iron dissolved in experiment D was 63 per cent of the amount of iron dissolved in experiment A. That means that the amount of iron dissolved in experiment D is 37 per cent less than the amount dissolved in experiment A and I think that is all Mr. Owen wants.

Q. Yes. And the only difference between the two runs was the fact that in the D runs the acid contained lead chloride? A. Yes, sir.

The Court: I don't know. You say the only reason it was was because it contained less chloride? A. Lead chloride.

Mr. Owen: The A runs contained no lead chloride and the D runs contained a saturated solution of lead chloride.

The Court: Yes.

Q. Now, on this page N, run A was the blank. A. Yes.

Q. And what did you use in that, is that C. P. acid? A. Yes. All of these were C. P. acid. This is my second experiment, Your Honor, carried out in the same way as the first, except that it went over a longer period of time.

Q. That test was ninety-six hours? A. Yes, sir.

The Court: That is in the clear acid? A. Run A was with plain acid; yes, sir.

Mr. Owen: And run C had the lead chloride in to the saturation point? A. Yes, sir.

The Court: How long did that first HCl plain blank run? A. I think it was fifteen or sixteen hours. Fifteen hours.

The Court: That is the first one that we have talked about? A. Yes, sir.

The Court: And the saturated was the same fifteen hours? A. Yes, sir. All of the runs in test No. 1 were fifteen hours.

The Court: Yes. And now we have got the same thing only it is— A. (interposing): Run over a period of time of ninety-six hours.

Q. Now, will you state how much more iron was dissolved in run A on page N than was dissolved in run C? A. The way the data originally were prepared, the iron loss in run C was 14.09 grams, and in run A 22.27 grams. Run A was blank C. P. acid, and run C was C. P. acid saturated with lead chloride.

The Court: Then we have got two systems of weights here between their way, and now you are injecting another basis, the percentage basis here.

Mr. Owen: That is all we have been dealing with all through the case, percentage of reduction in corrosiveness, and I am trying to translate these figures into the same terms. A. No.

Mr. Lyon: I have been saying here we have just been comparing the actual amounts, or if you are going to try to make it in percentage, they are taking the reciprocal and figuring how many times as corrosive one acid is as another, compared to something in the patent. It doesn't mean—these percentages don't mean anything.

The Court: I am trying to follow both of you. A. Well, Your Honor, did you put down the actual weights lost in the period of 96 hours?

The Court: No, I didn't get the actual weights lost in the 15 hours even. A. Would you like me to give you those?

The Court: Now, here I have a new set of figures. A. Would you like to have me give you those, or have them in

proportion? Actual loss in the first experiment on the average was by analysis 2.5—there were two runs, one of them lost 2.586 grams and the other one lost 2.907. Now, they are supposed to be duplicates. Now, panel "C," which were the ones that were in the solution containing lead chloride, this is all in test 1, Your Honor. I am referring to page "G," going back again to test 1, I thought I might as well get all the results in the same form.

Q. Well, "C" wasn't in the question regarding page "F"? A. It is "D."

The Court: I think I understand, I will listen instead of trying to keep any notes on it at all, and I will let my ears serve me. A. Going back to page "N," Mr. Owen, the relative amount of iron dissolved with lead chloride and without is 61.4 per cent over a period of 96 hours. Stating it the other way, there is about 39 per cent reduction or less corrosion in the second case than in the first.

Q. (By Mr. Owen): That is less where the lead chloride was present? A. That is right, over the whole period of 96 hours.

Q. Now refer to page "P-2"; what was that test? A. Now, this test is simply the test made exactly the same as the first test, except that instead of comparing with plain acid, acid saturated with lead chloride, I compared with plain acid, acid containing 500 parts per million each of lead and iron and 5 parts per million of copper.

Q. And in that test, "A" was the blank? A. Yes, sir. And "D" was the acid containing the metals. In both cases the specimen was alone in the beaker.

Q. Well, now, will you compare tests "A" and "D" as to their relative corrosiveness? A. Yes, sir. The actual losses in weight in case of "A" was 2.58 grams; in the case of "D" 1.28 grams. That means that in run "D" almost exactly 50 per cent as much iron was dissolved as in the case of run "A."

Q. And now will you compare run "F" with run "A," stating first how "F" differed from "D"? A. Run "F" differed from "D" only by the fact that there was in

the solution along with the iron panel a piece of lead which was not touching the steel, and run "F" the amount of weight lost was 1.08, let's call it, grams, and in that case about 41 per cent as much steel was dissolved as in the case of run "A."

Q. So that putting it the other way about—run "F," with the added chlorides of iron, lead and copper, plus a lead plate which was in the acid, reduced the corrosiveness 59 per cent, is that right? A. It seems to be, yes.

Q. And comparing F and D, the only difference was that F had this loose lead plate in and D did not? A. That is right.

Q. And the difference between those two was about 9% in favor of "F"? That is "F" was less corrosive than "D" by 9%? A. That is right. However, I think if you will refer back to page 6 of my table you will find that the losses in weight do not differ. That is between experiments D and F of the fourth test which you were just referring to, doesn't differ any more than the two individual samples in tests D1 and 2 of the first test. In other words, I would say that difference was entirely within the variation to be expected.

Q. So that you would claim that conducting tests in the manner in which you conducted the ones we have referred to, you can get quick, accurate, reproducible results, do you not? A. Moderately so I can, of course.

Q. Within what per cent would you say? A. Well, that depends on how much attack there is. Generally speaking, I would get more closely agreeing results where there was a lot of some substance which had some restraining effect than where there was less, other conditions being the same.

Q. Then I take it from what you have said this morning that you agree with Dr. Bartell and Dr. Prutton that adding lead chloride to C. P. hydrochloric acid of 15% strength, reduces the corrosiveness of the acid some 40 to 50%, isn't that right?

Mr. Lyon: Now, I object to that on the ground as I

remember Dr. Bartell's testimony, and I believe Dr. Prutton's, they stated the lead chloride alone had no more than 12% value.

Mr. Owen: All right, I will pass that.

Q. You show more protection due to the presence of the lead chloride than they did? A. Yes. It may be due to the fact that I used stronger solutions of lead chloride.

Q. Well, what would you say as to your agreement with them regarding the effect of adding around 5 parts per million of copper, lead and iron to a C. P. hydrochloric acid solution, 15%? A. Well, if you will correct that to mean 500 parts per million each of lead and iron and 5 parts per million of copper I would say that my results give relative rates of attack of about the same order of magnitude as Dr. Bartell has indicated on my particular scale under these conditions.

Q. Have you ever run any tests similar to those run by Mr. Hathorn? A. No.

Q. Have you run any large scale tests on this matter concerning which you have testified this morning? A. No, not with any attempt to measure the amount of dissolved iron. I have run large scale tests in the pickling shop where we put through tons and tons of steel and measured the dissolved iron in the acid.

Q. Now, I call your attention to sheet 1 of Mr. Hathorn's curves, DX-280, and to the fact that according to his testimony those runs were made in the following chronological order (you may write them down if you like) 5, 6, 3, 1, 4, 2. Now, referring to the exhibit, 5 was run with commercial acid plus the lead plate and 6 was run with commercial acid plus a lead plate and Tergitol. Now, in view of that fact, what would be your opinion as to whether or not the walls of the tank were coated with lead at the end of run 6? A. At the end of run 6 I imagine there might still have been some slight specks of lead on the walls, but I can't say because the plate had been disconnected. To what extent that lead had been removed, I wouldn't be able to say.

Q. Well, at the point where the plate was disconnected, what would you say as to the walls having been covered with lead? A. I would say that, on theoretical grounds at least, and on the basis of what I found, there would probably be lead on the walls.

Q. You do not know what effect the continuing of that run for 24 hours without the lead plate connected might have had on the amount of lead on the walls of the tank? A. From the course of the curve, I would suspect that lead was being removed fairly fast.

Q. You referred to run 3 which followed run 6, and which was a commercial acid run, and you find that it shows a lower rate of corrosion than di runs 1 and 2, which came later, and which also were run with commercial acid, with no addition. A. That is true.

Q. Now, what would you say as to the probability of some of the lead accumulated on the walls in runs 5 and 6 having remained on the walls during run 3? A. Merely on the face of the curve, in the order you have given me, that could not be excluded. However, after hearing Mr. Hathorn's testimony as to how he cleaned the tanks, I certainly would not expect much lead to be left.

Q. You do notice that run 3 which followed immediately after 5 and 6 with the lead plate in the acid, run 3 showed quite considerably less corrosiveness than did runs 1 and 2, which came later? A. Yes.

Q. Now, the run numbered 1 on this exhibit was a commercial acid run, and shows a high rate of corrosion? A. Yes, sir.

Q. Run No. 4 followed that, and that was a commercial acid run, plus a lead plate, and it shows considerably higher rate of corrosion than does run No. 5, which is also commercial acid, with a lead plate, isn't that true? A. That is true.

Q. Can you account for that in any way? A. No.

Q. Might it not be accounted for by the fact that the commercial run No. 1, having no lead in the acid, ate up, or dissolved all of the lead from the walls of the tank, so that

when run 4 was run it had no reserve protection, and the only protection it got was from the lead plate which was in the tank in run 4. Would that be a reasonable explanation? A. You are entitled to interpret it that way if you want to. I don't think there is any evidence for it.

Q. Have you any other explanation for it? A. No. I don't think I need any.

Mr. Lyon: I think you ought to make a little more complete answer than that. A. After run 1 came run 2.

Q. (By Mr. Owen): Oh, no.

Mr. Lyon: That is not correct. A. Came run 4.

Mr. Owen: That is right. A. And after run 4, in which, presumably since the rate of corrosion was decidedly lower than run 1 which immediately preceded it, one might presume that the tank had once more gotten coated with lead to whatever extent such treatment coats it with lead. Then it was cleaned in the same way as the tank was cleaned after run 5, and we got run 2, and now run 2 isn't—run 2 followed run 4 just as much as run 3 followed run 5.

Q. Yes. And during run 4 the walls of the tank became covered with lead, did they not? A. I think so.

Q. And then run 2, which immediately followed with commercial acid, showed a considerably lower rate of corrosiveness than did run No. 1. A. No.

Q. Isn't that true? A. I don't think so.

Mr. Lyon: Wait a minute. I want to object to the question because the evidence is that between runs—those two runs, the tank was completely cleaned and the witness hasn't admitted and there is no evidence that there would be any lead remaining on the plate following such a cleaning.

Mr. Owen: Mr. Douty, what is your opinion as to the effectiveness of sulphuric acid in dissolving lead?

Mr. Lyon: Plus the reversing of the polarity and the other things that were done in cleaning the tank.

Mr. Owen: Well, now, Mr. Lyon, I would like to conduct my cross examination.

Mr. Lyon: Well, I don't mean to interfere.

Mr. Owen: But you do.

A. Well, Mr. Lyon, sulphuric acid is fairly resistant—I mean lead is fairly resistant to sulphuric acid when the lead is there in some appreciable amount, and the reason is unquestionably due to the fact that lead sulphate, the product of the reaction, is quite insoluble. Now, from my experiments, on which some doubt could be cast, anyway, I find that the amount of lead that might be deposited is from three to five millionths of an inch, and I certainly don't think that amount of lead would withstand forty-five minutes to an hour as anode in ten per cent boiling sulphuric acid, besides which, at the end, particularly when the surface was scrubbed with a steel wire brush, it was rinsed with more boiling water, and finally washed with fifteen per cent hydrochloric acid, which is a better solvent for lead sulphate than is water or sulphuric acid, so that the final wash with hydrochloric acid would probably have removed, in my opinion, all of the lead sulphate which might have remained as an insoluble precipitate in the tank. I would say that the chance of there being any appreciable amount of lead in the tank is small. I cannot exclude the fact that there might be traces of lead on the walls.

Q. And that that might account for the fact that commercial acid run 3, which followed some of the lead runs, was less corrosive than commercial acid runs Nos. 1 and 2?

Mr. Lyon: I would like to have the record show that the witness pointed to run 3 at a time of twenty-four hours, and I assume from that he is contending that whatever amount of lead the witness has said possibly might be on the plate would still be affecting the commercial acid after twenty-four hours in the commercial acid.

Q. (By Mr. Owen): Well, maybe the witness knows what that means, I don't. A. Well, irrespective of the interpretation, I think that you would be stretching a point to draw any such conclusion as implied in the question without a whole lot of further evidence. I will say that if there had been lead left in small quantities on the tank

wall, which I do not know that that is true, in fact I think it is not, at the beginning of run No. 3 it would have been gradually removed and we would have expected this curve to show an upward trend with time, which it doesn't do, and the reason I assume that is because in general those experiments in which there have been a lead plate connected, which was then disconnected, generally do show an upward trend with time in general after the disconnection.

Q. And you cannot offer any explanation for the differences in the rates of corrosion in runs 1, 2 and 3, can you? A. No, I can't offer any explanation.

Q. Nor can you offer any other explanation for the differences in runs 4, 5 and 6, each of which contained the lead plate? A. Well, I don't know what conclusion to draw about experiment No. 6. The rate of corrosion of that tank over 24 hours was essentially zero. It started out at a value of about 40 ounces per thousand gallons of iron and it ended up at about 56 parts per million, as near as I can read that chart—rather ounces per thousand gallons, as nearly as I can read the chart. Now, it may be the Tergitol had something to do with that, I don't know.

Q. That is, run No. 6, which shows a very low rate of corrosion, was commercial acid plus the lead plate plus Tergitol and it differed from runs Nos. 4 and 5 only in the fact that it contained Tergitol? A. Yes, that is all that appears on the chart.

Q. And that would indicate the Tergitol had an inhibitive effect, would it not? A. No.

Q. What does it indicate? A. If it indicates anything, which is questionable, it would indicate that Tergitol assisted the Menaul action in protection; a totally different story. No evidence that Tergitol by itself has any inhibiting effect.

Q. But the evidence is that when Tergitol is present the inhibiting effect of the lead chloride is increased, is that it? A. No, sir, that hasn't been demonstrated by anything here.

Q. How would you account for the fact that with the Tergitol present the rate of corrosion is so much lower than it was in the two runs when it was absent? A. I don't know, I haven't made any great attempt to account for it; I shouldn't be at all surprised if Halliburton could patent that.

Q. Now will you turn to the second sheet, DX-281. In this sheet the order was 1, 4, 2, 5, 3. Now, in this sheet, run 1, which was the commercial acid run, shows the highest rate of corrosion, does it not? A. Yes, sir.

Q. And run 2, which is commercial acid plus Tergitol, shows a considerably lower rate of corrosion? A. Yes.

Q. And run 4, which has the lead plate in, intervenes between runs 1 and 2?, A. That is correct.

Q. So that the lowered rate of corrosion in run 2 might have resulted from the fact that the tank took on a coating of lead in run 4, is that true? A. No, I don't think that is true; I mean, I do not say it is untrue, but I certainly do not interpret it that way.

Q. It would be true if it were assumed that the tanks were not thoroughly and properly cleaned, would it not? A. Once more I think not; the general course of the curve for run 2 is concave towards the horizontal axis, rather than convex towards the horizontal axis, as you would expect had the tank had a lead coating on it to start with.

Q. Then the only way that you can account for the lowered rate of corrosion in run 2, as compared with run 1, is the presence of Tergitol in run 2? A. That plus the uncertainty in the exact rates of corrosion, or the lack of complete reproducibility.

Q. Now will you turn to sheet 3, in which the order was 1, 4, 5, 2, 3, and will you here compare curve No. 1, using commercial acid, with the dotted portion of curve No. 4, which indicates the rate of corrosion after the lead plate was disconnected and the tank cleaned? A. Yes, sir.

Q. I understood you to testify that from the point where the lead plate was disconnected in curve 4, the curve showed substantially the same rate of corrosiveness as that

in curve 1, using commercial acid? A. Within what I think has already been indicated to be the range of reproducibility I would say that is so.

Q. Well, now, isn't it a fact that if you compare the portions of the curve after the lead plate is disconnected in curve 4, that the corrosiveness in 4 was considerably lower, or substantially lower than that in curve 1? A. Well, it is somewhat lower.

Mr. Lyon: At what point is that?

Q. Take from the 24-hour point the next 20 hours, in both of them, and state what the loss in weight was? A. Well, let's see, taking the first curve No. 4, starting at 24 hours, we go from 19 ounces per thousand gallons up to 159 ounces per thousand gallons, which is a gain of 140 ounces per thousand gallons in 20 hours. Now, do you wish me to compare that for the first 20 hours of curve 1, or with the time from 24 on? I don't know whether that is on the curve or not.

Mr. Hathorn: It is not on the curve.

Q. Take the first 24 hours—the first 24 hours then. A. That starts out with 6; that goes from 6 ounces per thousand gallons to 209 or 203—I think it is 203; roughly about 70 per cent as much corrosion in the hours from 24 to 44, on curve 4, as in the hours from zero to 20 in curve 1.

Q. Well, now, isn't it a fact that the only difference in those two runs in the period you have used for comparison was that commercial acid run No. 1 wasn't preceded by a lead plate run and that the portion of run No. 4 which you have considered was preceded by a lead plate run? A. That is correct. That was the object of the experiment.

Q. Can you account for the lowered rate of corrosion in any other way than being due to the fact that the acid contained dissolved metals in run No. 4 after the plate was disconnected? A. I cannot account for it by any mechanism that I can tell you about but if you turn back to sheet 1 and make the same computation—theoretically the tank should be clean at that point because after the cleaning operation it should be clean.

The Court: It was disconnected at that point? A. Then the tank was all cleaned out, the acid poured back into it again.

The Court: As I understand, the point there was he was saying how nearly was this (indicating) parallel with your commercial acid from that time on. A. I say this is about 70% of the slope of that (indicating).

The Court: And now he is asking you if the difference between that isn't due to what was in the acid, and you are answering this was within the range. A. That is correct, and I wanted to prove that by reference to the first chart in which we had two identical runs.

Mr. Owen: Now, referring to curves 3, 4 and 5 of sheet No. 4, DX-283, isn't it a fact that they show practically no break at the point when the lead plates were disconnected? A. That is correct.

Q. They continue right on just as though the lead plate had not been disconnected? A. That is correct. And a curious thing is curve 6 shows a sharp break which should be an identical one with curve No. 4.

Q. Now, turn to sheet No. 5. In this sheet, curves 5, 6 and 7 show no break in slope when the lead plate was disconnected? A. I think you are mistaken about that, Mr. Owen. I think you will find a considerable change of slope in curve 6, for instance, between the early and late parts. I haven't computed what the amount is, but I think it is obvious that the curve has a higher slope. A little hard to see on a curve already so steep, but I think anyone can see, neglecting that slight loop at the end of twenty-four hours and continuing on, that this slope is getting higher and higher, faster and faster, as compared with the lower part of that curve. I think anybody can see that without having it calculated. I may have made some calculation on that. I will see.

Q. Now on sheet 6, this represents runs in hard steel tank No. 1, with copper, lead and iron added to commercial acid? A. Yes, sir.

Q. As I recall, when you referred to this sheet before

on direct you stated that you couldn't make any sense out of the curves on this sheet, is that right? A. That is right.

Q. You can't account for them? A. No.

Q. Well, neither can we. A. All I think I said before was that this group of curves, for instance 1, 2 and 3, is that they might be singularly good members of a series that were supposed to be duplicates, where they are not supposed to be duplicates.

The Court: While you are on a different subject, which is one which doesn't show practically anything, I want to ask you, Mr. Owen, are you through with showing from these sheets the curves that you wanted to call to my attention for which you claim that subsequent experiments did not show as great corrosion for the reason, as I take it, you claim they were not thoroughly cleaned. Well, they might be either way, one way, and his theory is that there was a tolerance or range within which one group fell and another lower range within which the other fell, and while they varied a lot there still was enough, and I have got to watch that in the same way again too, but these experiments, some of them, I want a hundred before I reach a conclusion about them, to tell you the fact about it. They are that kind of experiments.

Mr. Owen: And these tests of Mr. Hathorn, there are comparatively few runs under the same conditions, Your Honor. There was no attempt to run two or three of the same kind and take an average.

The Court: Someone tell me how many there are here where the subsequent run went higher than the first one after the cleaning; can somebody tell me that? A. Well, Your Honor, would you mind rephrasing that; I mean do you mean to say—

The Court: Well, now, Mr. Owen has shown here that your first run went higher than your second run, and I take it by his questions that he is inclined to think that the tank wasn't thoroughly cleaned, had lead on the wall of it, and that is the reason why the second run didn't get as high. Now, if you find some of these that go the other way, why,

I think that would be very important for me to know, and I haven't any idea about it. I just followed him. A. If I may answer that, Your Honor, I think Mr. Owen's point was this, and if I am wrong Mr. Owen will call me for it. The first run on this sheet No. 1 was No. 5, which was a run with a lead plate in. And that was followed by run 6, another one with a lead plate in the tank. Remember, of course, that the tank was cleaned after each run as well as we know how, as well as Mr. Hathorn knew how. Then after run 6 came run 3. Now, after run 3, which was plain acid, no lead plate, Mr. Owen says, "Now, that one probably represented a nice cleaning operation, merely leaving that acid in there for 48 hours." However, it was all cleaned out over again by the usual method, and then came run 1, Mr. Owen says, "Why did run 1 go so much higher than run 3?"

The Court: Run 1 is just because it is the highest there.

Mr. Allen Owen: It is commercial acid.

The Court: But it was made the last one? A. Yes, of that series, as far as we have gone. In other words, Mr. Owen says that the reason probably that run 3 is lower than run 1 is because it probably had residues of lead from the first two experiments with the lead plate. And he says that is demonstrated by the fact that the next run jumped up a whole lot, and I say it does not prove it at all, because run 2 comes down again; now, I don't know where we are.

Mr. Allen Owen: Run 2 comes down again, Your Honor, because it is subsequent to their lead plate run, which is run 4.

A. Of course run 2 is higher for the first four hours and lower here (indicating), it is hard to say—

The Court: In this talk to me about time now, kinds of runs there, are there any there that the later run is lower.

Mr. Owen: That is where a commercial run followed a lead run, is that what you mean?

Mr. Lyon: Put it this way: is there any there that show the opposite effect of what Mr. Owen pointed out?

Mr. Owen: Yes.

The Court: His contention is that cleaning wasn't complete and therefore the subsequent run wasn't as high as it would be?

Mr. Owen: That is right.

The Court: Now, are there any there that go down? I haven't any notion about it at all. A. I will see if I can find them, Your Honor. Do you mind if I consult Mr. Hathorn?

The Court: Yes, both of you look at it, all of you look at it.

Mr. Owen: Put the order on sheet 4.

Mr. Hathorn: 3, 1, 6, 4, 7, 5, 2.

Mr. Owen: We have got mixed up on our order here. I have one order, and Mr. Hathorn has another.

The Court: That kind of restores my loss of egotism. I got almost an inferiority complex here, and had it until I hear the rest of you tell me about some of your troubles, and that kind of restores me.

(Counsel, the witness and others conferred at the chart board.)

The Court: This is a necessary parley, and you haven't proved anything without this. If you come through there and prove something, then I have another question to ask you, just as soon as you make this riveted quite strong—then I am going to ask you another question.

A. In this particular chart, No. 5, the experiments were run in the order of 4, which is plain commercial acid. This was the first one run (indicating) 4. After that came a lead plate, 5, which had a lead plate in it. Then came No. 2, which is up here (indicating). Then came No. 3. That had a lead plate, and also Tergitol. Then it went to No. 1, which did not have the lead plate or the Tergitol. So when this—in this particular instance, the subsequent runs were higher instead of lower (indicating).

The Court: Which is the first one? A. No. 4.

The Court: The lowest one here, of the plain commercial acid, that is the lowest one, isn't it? A. Yes.

The Court: What does this do to your theory, Mr. Owen?

Mr. Owen: This is the sheet that Mr. Douty said he couldn't make anything out of, and we said we couldn't either.

Mr. Allen Owen: This one shows no electrical effect in the run which was supposed to have leaded up the tank. That is the only one that Mr. Douty will agree there is no change in the slope? A. I cannot see any break at all there. It looks to me as though that is a general kind of curve there, though (indicating).

Mr. Allen Owen: There is very little if anything left on the side of the tank.

Mr. Hathorn: The lead plate reduced the corrosion, though.

Mr. Allen Owen: I grant you that.

The Court: Doesn't this one disturb your theory, or tend to; in other words, if that were just reversed, you would be citing it to me as another good example (indicating). The next question I was going to ask you, Mr. Owen, was, I take it that this agrees with your theory, but we will suppose it does not, if you had some uniformity—every time the second run went lower, then the results that you claim from that would be that the wall had been coated by the lead plate, which was connected up to the iron in such a way that it prevented corrosion to a certain extent. My next step is, to the extent that it does that, that is without putting any inhibitor fluid that they use, isn't it, to the extent it does that?

Mr. Allen Owen: All we claim for those things is to show the more or less faulty technique that Hathorn used, because his results are entirely unpredictable.

The Court: I say, that would follow right along, that independent of what is in the solution, a lead plate connected to the iron does give protection to the iron?

Mr. Allen Owen: There is no question about that.

The Court: The thing the argument is about is whether by giving that kind of protection it also leaves

some of the lead in solution, which, as lead in solution, gives an added protection too.

Mr. Owen: That is true.

The Court: Now, is there any dispute of that by the other side?

The Witness: I dispute it, Your Honor. And I think I have a report in my evidence to prove it.

The Court: You say it didn't result from that? A. Yes, sir.

The Court: But the main thing resulted from the lead connected with the iron? A. That is right.

Mr. Allen Owen: I don't think Mr. Douty disputes that after you take that acid out of the tank containing dissolved lead and then put a steel strip in there, I don't think Mr. Douty will deny the acid was less corrosive than before the lead was put in. A. To the extent the lead could act as a resistance, it would. We cannot deny that.

The Court: That is independent of the other, the electrical action? A. Entirely apart from that. The way I am informed, the defendant sets up a truck tank, puts acid in it, and when they get to the well, they dump it down the well. I have never been down a well, I never made a test on the well, Your Honor. So far as their own truck tanks go, this was done in a laboratory test, never done in actual practice. I claim Halliburton's protection in the truck tank is independent of whether anything goes into the acid or not.

The Court: You claim the lead plate connected with the iron while it is there and so connected gives a protection to the iron in addition to what is in solution? A. No, sir, a protection in the iron which is not improved but, according to my experiments, actually is impaired by any lead in solution.

The Court: But you do claim that lead plate connected with the iron is giving protection to the iron of the tank independent of whether there is any lead in solution in the acid or not? A. That is right.

The Court: That is their claim and you don't deny that, as I understand it?

Mr. Owen: Our contention is somewhat different from Mr. Douty's. We claim the main protection is from the lead chloride in solution and that the connecting of the lead plate may add something to it, and I think, as I understand—

The Court (interrupting): And if I had succeeded in this of showing that they were all that way, and convinced that always in the second one would add so much lead on by the first they didn't get it all off by this, would be just additional proof of that thing. Of course you were attempting to prove another thing but by doing that you would be proving the extent to which this lead plate connected with the iron did put a coating on the iron which protected it, which you are not complaining about under your patent and have no right to claim anything.

Mr. Owen: No. What we claim is that the lead, copper and iron which are in solution in the acid when it leaves the defendant's truck tank are the effective inhibitors in defendant's process.

The Court: Well, all right. But I think this proof brought out in the discussion does help to analyze this problem.

Mr. Owen: Now, I have just one more sheet of these drawings that I would like to ask Mr. Douty about.

The Court: I think it is very proper, and helpful, this discussion—we can't tell who it will help—but it does help in the understanding about it.

Mr. Owen: Now on sheet 7 will you compare curve No. 1 which is the C. P. acid run with Curve No. 5 which is a C. P. acid plus lead, iron and copper run at 10 hours, and point out what the amount of iron dissolved in each of those was at that point? A. Well, the C. P. acid containing lead, iron and copper, according to this test, at ten hours contained 210 ounces per thousand gallons of iron, and the plain C. P. acid contained 462. 210 and 462 are the two numbers. The blank is negligible in this particular run.

Q. Now, what is the difference in corrosiveness of those two solutions? A. Well, apparently, as expressed by the two numbers, which I have just read, 210 and 462.

Q. And would that show that the acid containing the copper, lead and iron chlorides is about 54 per cent less corrosive than the one without those metals? A. That sounds about right. However, I also call to your attention curve No. 3 in which a commercial acid containing no added metals whatsoever is also far less corrosive than the C. P. acid.

Q. Now, will you compare that curve No. 3, which is commercial acid, with curve No. 6, which is commercial acid plus iron, lead and copper? A. Commercial acid containing the lead and copper at ten hours dissolved enough iron to give an iron concentration of 151 ounces per thousand gallons, and for the plain commercial acid the number was 250.

Q. What reduction in corrosiveness does that show for the acid which contains the metals? A. Oh, roughly forty per cent.

The Court: Let me understand, and let me know clearly now whether or not that one where we found a reversal of the situation, namely, where the test with the clear acid without any lead having been previously used was more than that after the lead had been used, and the plate was cleaned, the reversal of it, was it on that sheet that both sides have said couldn't be made use of, or was it the other?

Mr. Owen: I think it was another sheet.

The Court: I want to get that clear. Which one was it on? A. In justice to these curves, I must say that one of those sheets out of which I said it is difficult to draw conclusions was the sheet No. 7 here, from which Mr. Owen has just asked me to draw a conclusion.

The Court: Which went the other way. A. Surely.

The Court: I know it. But I want to make it clear that here is one with decidedly the opposite results that nobody has contended for that purpose. A. That is right.

Mr. Owen: I believe I asked you a question as to what inhibitors or acid regulators or pickle control substances the American Paint and Chemical Company were manufac-

turing when you went with them? A. I have been thinking that question over during recess and I recall that when I became connected with the American Chemical Paint Company Mr. Gravell had tested a number of things and had finally found that bone tar oil, mixed with sulphuric acid, gave a product which was a reasonably efficient pickle control substance, and that is about as far as he had gone. Whether any of that had been used commercially at the time I joined the company, I don't remember, but some of it was used commercially shortly thereafter, I am sure.

Q. And that would be the first one, at any rate? A. Yes, sir.

Q. Will you tell us what that was, how it was made? A. I don't remember the proportions, and I haven't the formula with me, but it was made out of concentrated sulphuric acid and bone tar oil. It was a very unpleasant material to make and unpleasant material to handle, an evil odor. It was called "Rodine."

Q. Well, what is the name and formula of the first product your company made and sold as a pickle control substance or acid regulator? A. The first one I can find in the formulas of the company, and, therefore, it is the first one that I am sure that was used commercially, is known as "Rodine extract," and appears in our formula book as formula No. 71, under date of December 1, 1923. Now, I have reason to believe that there was an earlier formula for that, which probably didn't get into this formula book, because I find immediately preceding formula 71, a formula, No. 70, of the same date, which refers to "Rodine extract." However, since they were written on the same date, I am not sure that it wasn't referring to the same product.

Q. Which of them was manufactured and sold? A. Rodine extract was certainly manufactured and sold.

Q. What is the formula of the product that was manufactured and sold? A. The formula is very similar to the formula given in the Gravell patent in suit, at the top of the first column of the second page, except that it does not contain any arsenic.

Q. Well, then, it would be the formula which appears at the bottom of the first page, wouldn't it? A. Yes, that is very close to it.

Q. I wish you would explain just how that product was made. A. I will read the formula sheet here. It has directions. At the top of the formula sheet it says, "Tar oil," which means bone tar oil, ".476 gallons. Hydrochloric acid, .727 gallons." Mr. Gravell has here in parentheses after hydrochloric acid "1.200," but I know that we never had any commercial hydrochloric acid of that gravity, and he must mean 1.160, which is the gravity of 20 degree muriatic acid. We never had any 22 degree muriatic acid in the place. So that is really about 31 per cent hydrochloric acid. The official table of specific gravity of hydrochloric acid solutions, adopted by the Manufacturing Chemists Association, gives for 1.200—that would be 24.2 degrees Baume. Well, now, there isn't any such hydrochloric acid commercially. The strongest one we have ever had in the plant would have a gravity of 1.160, which is 20 degrees muriatic acid, and that was what was actually used, and that is 31.45 per cent HCl.

The Court: And there was .727 gallons of it? A. That is right, sir, of 20 degree Baume.

Q. Now, assuming that that formula called for 20° Baume hydrochloric acid, what was the proportion appearing of hydrochloric acid in the product? A. The total hydrochloric acid in the product would have been something like 20, 23, to 24%. But, of course, some of that hydrochloric acid would have existed there as salts of the basic materials in the tar oil.

Q. How much do you assume would have been consumed in neutralizing those salts or neutralizing the basic material in the tar oil? A. The tar oil consisted of approximately one-half basic material. That would have meant that there would be about 200 grams of tar oil bases per liter of product and the average molecular weight of those bases would have been somewhere in the neighborhood of 300. Therefore, about two-thirds normal hydro-

chloric acid would have been sufficient to neutralize them and the acid actually used was approximately 7.3 normal. So that I should say about 85 to 90% of the hydrochloric acid I have mentioned would still have remained free. So there would probably have been somewhere between 15 and 20% of free hydrochloric acid in the product.

Q. Now, will you explain the process of making this product which is shown in the formula at the bottom of page 1 of the patent and just explain it in some detail, please? A. I will read the directions on the formula sheet, written in Mr. Gravell's style of typewriting—"The tar oil is first placed in the agitator and the hydrochloric acid while stirring. Considerable heat will be generated. The agitator should be covered and connected to a chimney to take care of the vapors evolved. The agitation should be maintained for approximately 1 hour, and then the admixture should be allowed to settle for twelve hours when it will be found that it has separated into two layers, with a contraction in volume of .013 gallons. The bottom layer consists of Rodine extract and will measure 1.00 gallon in volume, and the top layer will consist of oil and will measure .19 gallons in volume, as shown in the following table," and the figures are retabulated showing the loss in volume and oil separated.

Q. And what is the pickle control? A. The bottom layer is Rodine extract.

Q. And what proportion is that of the whole? A. About a little over eighty per cent.

Q. Then the product that was actually shipped was this bottom layer with the hydrochloric acid that had been taken up in the process of manufacture; is that right? A. Yes. All the hydrochloric acid remained in the bottom layer.

Q. And what was the purpose of using the hydrochloric acid in connection with that bone oil extract, or that bone oil, rather? A. To extract the basic materials from the bone oil, which basic materials were the active inhibiting ingredient, and hold it in solution. There was

also a secondary effect which is not particularly important here, except that it is a curious fact that small amounts of hydrochloric acid have an inhibiting effect when added to sulphuric acid, so that there was a deliberate use of an excessive hydrochloric acid here because it increased the inhibiting effectiveness of the material.

The Court: And by that you mean inhibiting as to eating iron? Reacting with iron? A. That is right, sir.

The Court: Hydrochloric acid on sulphuric. Sulphuric itself is corrosive. A. Yes.

The Court: And will react with iron, but you put in a little bit of hydrochloric, which in itself and alone will eat iron and that combination is less corrosive than either one of them? A. That is correct. I found a reference to that in some of the journals I have read in preparation for this case. In fact, in some of the references which the plaintiff has cited.

The Court: In other words, they find in themselves some satisfaction that is exhausted for their reaction with iron; they take it out on each other. A. Apparently.

Mr. Owen: That product you say was called Rodine? A. Rodine extract.

Q. And it was sold and used in what way, for what purpose? A. The only purpose that I remember Rodine extract ever having been used for is as an adjunct to the pickling of steel articles.

Q. It was put in the pickling bath? A. Yes, in small proportion, of the order of one-half to one per cent of the concentrated sulphuric acid, which was a constituent of the pickling bath.

Q. How was it shipped? A. In glass carboys.

Q. Now, what other similar product, if any, was made and sold by the American Chemical Paint Company shortly after you went with them? A. The next product that appears in the book was Rodine No. 3, which bore our formula number 85 and the date June 18, 1924. And that consisted of a material very similar to the previously named material, except that an effort was made to remove

a certain amount of tarry substance that was likewise dissolved by the concentrated sulphuric acid from the tar oil, and which was objectionable in the pickling operation because it had a tendency to leave spots and deposit on the pickled metal.

Q. Was it made in the same way as the other Rodine you have previously referred to? A. The final proportions were essentially the same, but the method of manufacture was a little different in that the extract was first made as before and separated from the waste oil and then the extract was treated with alkali so as to throw out the free bases, and the free bases were redissolved—or, rather, let me put it this way: the extract was made which was somewhat more dilute than previously made, so that it wouldn't take up so much tar and then the bases were liberated from the extract and redissolved in hydrochloric acid in essentially the same proportion as before, so as to have a material that made a nice clean water solution without tar to go in the pickling bath.

Q. And was the final product about the same, you say? A. Yes, very nearly.

Q. Same proportion of hydrochloric acid? A. Yes, it had, I see by the book, .753 gallons of hydrochloric acid in a gallon of finished product, whereas the other one had .727. It had a trifle more hydrochloric acid in the finished product. It worked the same as before.

Q. What was the number of the next formula? A. The formula that I just read to you, Formula No. 85, has a notation on the top of the page, in Mr. Gravell's handwriting, "Discarded, see Formula No. 92."

Q. That is, the one that you have just referred to, was discarded? A. Yes. You can see here, we have, curiously enough, Formula No. 90, and this is also marked discarded for Formula No. 92. Formula 90 appears on October 29, 1924, and Formula No. 92 is on November 12, 1924; so that the material of Formula No. 90 apparently was short-lived in our formula book, and was immediately replaced by the November 12, 1924, material, and that is

the material Formula 92 on which Mr. Gravell has written "Standard."

Q. How was that made? That is, how did it differ from the other? A. May I state that before Formula No. 92 became standard, the October 29th Formula No. 90 was made exactly the same as Formula No. 85, except that a solution of arsenous oxide was added to it, and that was also added in the case of Formula No. 92, which is the standard material of November 12, 1924.

The Court: From what you have given me, I have the notion that 85, and 90, were probably in their day standard, and that this pencil mark simply is the result of some day, we don't know just when, he just marked that, as the standard? A. Very likely, Your Honor, he was revising his formula book on that day, and he went through these formulas and said, these are discarded, and this one is the standard one, on that date, whenever it was.

Mr. Owen: Now, going on with your products, what was the next product put out, or that you say will comply with the formula at the top of page 2 of the Gravell patent? A. The next product which would approximately correspond to the formula at the top of page 2 of the patent was Rodine No. 2, treated, our Formula No. 105, of date April 6, 1925.

Q. What were these other earlier Rodines called by number? A. No. 3 preceded No. 2. Formula 92 was No. 3 Rodine and Formula 90 was No. 2 Rodine, and Formula 85 was Rodine extract; no, that was also Rodine No. 3. That goes all the way back to the first one I gave you to get Rodine extract, that is 71.

Q. How did this Rodine No. 2 differ from No. 3? A. It appears to be very nearly identical with it. For instance—(after examining document)—oh, I wish to make one correction in my previous testimony. I overlooked the fact that in Formula No. 90, .508 gallons of bone tar oil was used to make a gallon of finished product. In Formula No. 92, only .320 gallons was used. In other words, that was somewhat weakened for some commercial reason or

other. I do not think that Rodine No. 3 was sold over a very long period, because I see there on April 6, 1925, we had a formula for Rodine No. 2 in which once again almost a half a gallon, namely, .496 gallons of bone tar oil was used for making a gallon of finished product. So we seem to have restored the strength again, and made it under Rodine No. 2.

Q. It is your opinion that Rodine No. 3 was not sold very much? A. Well, it probably was not sold much beyond the early part of 1925. I did not mean to imply that there was not much of it sold there. I meant simply to say that it may have been extensively sold during that period, but the period during which it was sold at all was not very long. I cannot give you any figures at all as to the sales of this material, Mr. Owen.

Q. You don't know whether it was extensively sold, or only slightly? A. I cannot tell you. I have not got any sales figures.

Q. Well, then, your No. 2, appeared when? A. April 6, 1925. Now, it is curious that formula 105 which appeared on that date has Rodine No. 2 and then, in parenthesis, treated. There is nothing in the formula books here to tell me but I am almost certain that what they meant was that what was in this book as Rodine extract was for a very short time known in the company as Rodine No. 2, and this Rodine No. 2 which is marked treated, is the one which superseded that. Therefore, since we had never had an official Rodine No. 2 in the book we now started over again with Rodine No. 2, which is really subsequent to Rodine No. 3.

Q. And when did Rodine No. 2 disappear? A. Rodine No. 2, I don't think has disappeared yet. Rodine No. 3 disappeared.

Q. Referring to the formula at the top of page 2 of the Gravell patent, first column, has your company ever made and sold a similar solution using a metal other than arsenic? A. No. Not unless you include gelatin among the organic bases, and there is some doubt about that.

Gelatin was used in a material that we made which included gelatin and stannous chloride. I think it was Rodine No. 6. It was used in pickling baths. Sulphuric acid pickling baths, largely.

Q. What is the nearest thing you have manufactured and sold, that is, the nearest to this formula at the top of page 2 in which a metal other than arsenic was used? A. It is pretty hard to say what is the nearest thing. We sold the mixture I referred to which contained tin as a solid, as I recall. At a considerably later date, we sold the material called Murodine. That would be somewhere in probably 1935.

Q. And how did that differ from your Rodine No. 2, for instance? A. That was based on the patent of Saukitis if I am not mistaken, patented some time in 1937 or '38, and it was for a combination of copper with certain organic materials as an inhibitor in hydrochloric acid. That was 1936. The Saukaitis patent is dated August 4, 1936, No. 2,049,517.

Q. What was the formula under which Muridine was made? A. I prefer not to give you the formula in detail, but it contained copper chloride and certain complicated organic bases made by reacting aldehydes with amines.

Q. Did it have any hydrochloric acid in it? A. Yes.

Q. You gave the formula in your deposition, did you not? A. I think I did, or at least I gave you certain parts of it.

Q. I call your attention to your testimony on page 107 of the depositions taken in January, 1941, and ask you to look that over, and the subsequent pages, and see if you can give the formula for Murodine? A. Well, according to the deposition,—and I was reading from the formula at the time I testified—Murodine No. 101 is the one I am speaking of—it contains about fifty per cent by weight of a complicated reaction product of aldehydes and amines, and another active ingredient of an organic nature which I have here forgotten, and some copper chloride, and you asked me at that time, Mr. Owen, how much hydrochloric

acid was in the final product and I stated from the formula it was very close to eighteen per cent by volume of twenty degree acid, which would make it run about, say, five or six per cent of hydrochloric acid,—of hydrogen chloride.

Q. How much copper chloride was in that? A. About six-tenths of a pound per gallon, that is six-tenths of a pound of copper chloride dihydrate.

Q. How does that amount of copper chloride compare with the amount of arsenic trioxide in the formula at the top of page 2? A. The formula at the top of page 2 contains .125 pounds of arsenic trioxide and this contains .60 pounds of cupric chloride dihydrate. The arsenic computed as metal in the formula of the Gravell patent at the top of page 2 is .085 pounds in a gallon. Now, the copper in Murodine No. 101 is .226 pounds of copper per gallon.

The Court: The arsenic is less than the copper? A. Yes, sir.

Mr. Owen: Do you consider that this formula for Murodine 101 is substantially the same as that at the top of page 2, column 1, of the patent, except for the substitution of copper chloride for arsenic trioxide? A. It has a rough resemblance; I should say it is somewhat similar. The object of the copper in that formula, however, is not to make the material shipable in steel. We want the copper in there when the customer gets the material.

Q. Does the presence of the copper in Murodine 101 make it shipable in steel? A. Yes.

Q. Do you ship it in steel? A. No.

Q. How do you ship it? A. Glass or wood.

The Court: What is the purpose for your customer's use? A. That was designed for use in oil wells.

Mr. Owen: I am going to ask what your customers use Murodine for? A. It has been used in a number of applications, notably the cleaning of steel equipment which has lime scale on it, by means of hydrochloric acid. We sell hydrochloric acid which contains a certain percentage of Murodine as a material called chlorodine, which is used for cleaning out automobile radiators, boilers, and things of

that kind, but we had hoped to sell the largest amount of that stuff in the oil well treating industry, and we did sell some for quite a while.

Q. And you did sell some of it to The Dow Chemical Company, did you not? A. Yes, sir.

Q. And you shipped it to them in wooden barrels? A. That is right.

Q. You also sold some of it to the Halliburton Oil Well Cementing Company, didn't you? A. I am not sure about the Halliburton Company, Mr. Owen. I don't know whether we sold them Murodine or didn't. Mr. Spruance may have said we did. I don't know. I know we sold to the Dow.

The Court: As I understand it, if this patent of defendant's is any good, you have been infringing that if you shipped it to Dow in steel containers? If their patent is good? A. It is our patent, Your Honor, so we never gave any worry about that.

The Court: Oh, it's your patent. That is right. A. It used to be our patent until we sold it to Halliburton a few years ago. I think we have a license from Halliburton to use it in our own business.

Mr. Owen: Now, have you ever manufactured and sold any product other than Rodine and Murodine which corresponded to the formula at the top of page 2, with the exception of the metal used? A. No, I think not.

Q. Now, among the products which you have thus far named, which have had the largest sale? A. In gallons, Deoxidine. I don't know about the dollars. But the Rodine and Deoxidine have been the largest selling materials made or shipped under the Gravell invention.

Q. And the Deoxylyte has been a small seller? A. Not small, but it has been decidedly less than the other two.

Q. And the Murodines, where do they stand in the scale of volume? A. Murodines have been comparatively small sellers, and about the time we were about establishing a nice business in that respect, Dow stopped us.

The Court: By this suit, you mean? A. Well, by writing us a letter warning us not to sell the materials for use

in oil wells, and warning us of the existence of their patent and so we tried to sell the inhibitor to Dow and did so for a while, and then they ceased to purchase from us and that was the last time we supplied inhibitors for oil wells.

Q. Do you recall whether in that letter the Dow Company told you you could sell to their licensees as well as to them? A. I don't, Mr. Owen. No, I don't. I have the letter. I have seen it. But I don't remember that.

Q. So that your sales of products which you understand to come within the Gravell patent have consisted of Rodines, Murodines, Deoxidine and Deoxylyte, is that correct? A. There are two other minor products, one of them known as Murodine—no—Clorodine, which is hydrochloric acid to which has been added substances, including arsenic, plus arsenic; and then that other material to which I made reference a little while earlier, Scalolene, which is used, which was used for a while in removing contamination from glass molds.

Q. Well, all of these products which you have made and sold under the patent have been products which contain acid as one ingredient of the product, is that right? A. Yes, sir.

Q. And in the phosphoric acid solutions—that is Deoxidine, Deoxylyte, the percentage of phosphoric acid is high, is that right? A. Yes, sir.

Q. And in the others, the Rodines and Murodines, the percentage of acid is low? A. Relatively.

Q. Well, it is down around 15 or 20% isn't it, of the solution? A. Well, not these Rodines, it isn't.

Q. How much hydrochloric is contained in your Rodines, your Murodines, or any other products made under the patent? A. Well, I have already given you the figures on several products. Rodine No. 2, which corresponds very closely to the material at the top of the column I think I calculated this morning that that would have had between 15 and 20% hydrochloric acid in it. That is of hydrogen chloride.

Q. You never have undertaken to ship acids for gen-

eral use as acids under this patent, have you? A. Only one acid. Phosphoric acid.

Q. And that is this Deoxidine and Deoxylyte? A. We have called that Deoxylyte and have shipped it as inhibited phosphoric acid for several special purposes.

Q. Is that used for some purpose similar to the Parker process or any of them? A. No, these inhibitors are very deleterious in a process like that. They interfere with the action that is necessary to get your rust proofing on the steel.

Q. None of your products are shipped as acids, are they? A. No. They are not just shipped as hydrochloric acid, sulphuric or phosphoric acid.

Q. I show you an exhibit which was identified in connection with Mr. Spruance's testimony as Spruance Exhibit 7, and ask you if that is the label you place on these products when they are shipped? (Handing same to witness.) A. If Mr. Spruance said so, it is. That is an official label. The regulations of the I. C. C. require you to place such a white label on certain products.

Mr. Lyon: I was going to ask Mr. Owen that Mr. Spruance's deposition be received in evidence with all its exhibits, but ask it be considered read. I didn't think there was any special point in reading it, taking up time to read it.

Mr. Owen: That is agreeable to me. Either party can refer to it as they like.

The Court : Have you the letter here? A. I don't know exactly the answer to your question, Your Honor, but I have a letter here which gives me some dates. The first sale of Murodine made by the Thompson-Haywood Company of—Haywood Chemical Company, of Tulsa, Oklahoma, to Dowell, is reported here as being made in 1935, but sales may have been made earlier than that.

The Court: When did you quit? A. We quit selling to Dow in 1937, January 16th.

The Court: Well, but did you quit selling to anybody? A. No, sir, we still sell Murodine in comparatively small

quantities for use in cleaning out water jackets of engines and radiators and boilers.

The Court: You quit for wells, did you, at that time? A. That is right, sir.

The Court: What amount of business was that, about, that you stopped, can you tell me? A. I haven't any idea, but I think it will appear in Mr. Spruance's deposition.

Mr. Owen: In shipping these products you have referred to, are they sealed or unsealed during the shipping operation? A. Sealed.

Q. Do you store them in stock? A. Yes, we store them. Not usually tightly sealed. We usually leave the bung loose when they are standing out in the hot sun which they generally are; they are generally stored in a yard.

Q. If you store them inside, you tighten the bung down? A. Ordinarily.

Q. Now, I show you three labels which were produced and identified in connection with your deposition, one of these marked Plaintiff's Douty Exhibit 1, and another Plaintiff's Douty Exhibit 2. Those are both Murodine labels, No. 101. Can you tell what the difference between those labels is? Why the two of them have different dates or what— A. Yes, the first one was printed in 1934 and the other one in 1940, to start with. In 1934 we had only one patent on there, namely a patent to a man named Chamberlin, I think, which we own. That patent was the only patent we had on the material at the time. It says on there "Other Patents Pending." It turned out that I found another patent that should have been on that label, which wasn't another patent of Chamberlin's. Then, in addition, it bears the Saukaitis patent number.

Mr. Owen: I will offer the earliest Murodine label as PX-306.

(Whereupon the label was marked PX-306.)

Mr. Owen: Now look at this Exhibit 306 and read into the record the patent number or numbers appearing thereon. A. It says Patent U. S. A. 1,719,649 Other Patents Pending. That is a patent to Chamberlin.

The Court: That was a formula patent? A. Yes, a patent for a certain kind of an inhibitor.

The Court: The ingredients that went into it? A. Yes. A certain type of reaction process it was.

Mr. Owen: That was a process patent? A. I am not sure. I don't think so. I am only testifying from memory. You have all the patents.

Mr. Owen: I offer the later Murodine label as PX-307.

(Whereupon the label was marked PX-307.)

Q. Please read into the record the patent numbers appearing on this PX-307 and state who the patentees are and what they refer to. A. U. S. Patent 2,049,517—that would be Saukaitis patent. The next one—Patent Canada 1937—and that is doubtless the Canadian patent corresponding to the Saukaitis U. S. patent. And then it says For Use in the Processes or Solutions of the following patents—U. S. numbers 1,719,168 and 1,719,649. Those are both Chamberlin patents.

Q. You don't find the Gravell patent in suit on either of those labels, do you? A. No, sir.

Mr. Owen: I have another label here for Rodine, which I will have marked PX-308.

(The label referred to was thereupon marked PX-308.)

Q. Will you read into the record the patent numbers appearing on that label, and state what they cover? A. This label is for material known as Rodine. It was Rodine liquid No. 102 for muriatic acid. That material did not retain the name "Rodine" No. 102 very long. It is now known as Murodine 102, and it consists of a solution of organic inhibitor. It is not acid, and, therefore, it could not have the Gravell number on it. However, it is Chamberlin's patent number, U. S. Patent 1,719,168. It also says, "Other patents pending."

Q. Do I understand from your last answer that you consider the Gravell patent to cover only acid solutions? A. Certainly, materials for use in acid solutions, such as the composition described in claim 7.

Q. The Gravell patent does contain several compositions of matter claims, numbers 5 to 8? A. Yes.

Mr. Owen: How long, in your opinion, Mr. Douty, if you were going to ship acid or if you were going to store it, that is, a corrosive acid, what life would you expect to obtain from an oil drum, in order to consider it a safe procedure, to store or to ship that acid in such a drum. A. The answer to that is the same as the answer of the famous mechanical engineer to the question "Is a boiler safe?" It is safe if it doesn't blow up.

Q. How would you find out whether or not these drums were safe or not, try them out and if they blew up they wouldn't be safe, and if they didn't blow up they would be safe; is that the idea? A. Pretty near. But one could do better than that. You can screw a pressure gauge into the bunghole and find out when the pressure got excessive, over a course of time.

Q. What would you consider to be excessive pressure so as to render it unsafe to store or ship a corrosive acid in a steel drum? A. Any pressure which exceeded or approached the calculated safe strength of the drum. I have mentioned pressure because, you don't mind my explaining this, I mentioned pressure because the product of reaction of the acid with the metal is hydrogen, Your Honor, and hydrogen is a gas, and if it accumulates in the small space above the liquid until there is an excessive pressure, the drum would explode.

The Court: I supposed when you started you were inquiring about how long before it would eat through. Safe in that direction. A. It isn't safe; it doesn't have to eat all the way through.

The Court: But that is what you were asking about?

Mr. Owen: I am trying to get an idea of what would be a safe drum in which to store or ship the acid.

The Court: Well, what did you have in mind, whether the acid is going to eat a hole in it, or whether it is tight enough or strong enough, or what?

Mr. Owen: Well, I should say that there are two possibilities, and one would be that the pressure would blow the drum up, and another one would be that the acid corroded through.

The Court: This is the first I have heard about that blowing up business.

Mr. Owen: What would be the effect, Mr. Douty, if you placed a corrosive acid in a drum and closed the opening to the drum tightly? A. Well, if you filled the drum pretty near full when you started, which is the custom, in other words, a drum might hold, level full, fifty-three and a half or fifty-four gallons, and you put in fifty two gallons of liquid, that leaves a comparatively small air or gas space. Therefore, it doesn't require the introduction of a great deal of gas from whatever source to build up the pressure, and in the most cases long before the drum was eaten anywhere near through you could notice the ends of the drum, which is made like a barrel with flat heads, begin to bulge.

Q. And that would be a danger signal, do you think? A. It certainly would.

Q. What would you expect to happen? A. I would expect if you let it go long enough, that something would let go somewhere.

Q. It would blow acid all over the place? A. It certainly would.

Q. If a corrosive acid were placed in a drum for shipping in interstate commerce, such products, for instance, as you may have, how long would you expect would be a safe time to allow for that drum to hold? What would you think would be a margin of safety so that the drum would not be likely to blow up in transit or after it reached its destination and was stored temporarily until the purchaser wished to use it? A. That is hard to say. We have shipped many drums of material to Europe, acid material in steel drums; we have shipped it to India, to Indo-China, to Australia. We have shipped them pretty well all over the world, and some of those voyages are fairly long.

Q. Several months? A. I think several months would be a representative figure as to a maximum.

The Court: Any trouble with any of them? A. Yes.

The Court: Did some of them blow up? A. No, sir, not ordinarily. I do not think we ever had one blow up, that I recall.

Mr. Owen: Were those acids? A. Yes, sir.

Q. Or acid solutions? A. Well, we always used solutions in that sense, if they were not labeled acids, or some other name—

Q. Oh, Murodines, Rodines, and things like that, is that what you refer to? A. Those and the Deoxidine and the Deoxylyte.

The Court: When the hydrochloric acid eats iron, then the gas that accumulates is hydrogen? A. Correct.

The Court: Just the same as when it eats the rock formation, it is carbon dioxide? A. Yes, Your Honor.

Mr. Owen: Which one or ones of your products have you shipped on these long voyages? A. I have no records before me, but I fancy about every product that you ever heard of has gone on a long voyage.

Q. In those products which have been shipped in steel you used arsenic, did you not? A. Always.

Q. You never shipped any product on such a long voyage that did not contain arsenic? A. Correct. That is, in steel.

Q. Now, what is the practice of shipping sulphuric acid in steel? I don't mean by you—I mean general practice, if you know. A. Concentrated sulphuric acid is commonly shipped in steel, steel tank cars.

Q. And what do you mean by concentrated sulphuric acid? A. Sulphuric acid of 60° Baume or over. I think 60° Baume corresponds to—well, I will look it up—that is the weakest acid that is commonly shipped in steel. (Witness refers to records.) That is 77.67% sulphuric acid.

Q. That is, Mr. Douty, 60° Baume is 77.67%. A. Yes, that is right, per cent sulphuric. H_2SO_4 is 77.67%. As a matter of fact, Mr. Owen, most sulfuric acid is shipped at 66° Baume, where it is 93%. It is not commonly considered safe to ship 60°.

Q. It is considered safe to ship 66° Baume sulfuric? A. Yes, sir.

Q. And what is the per cent? A. 93%.

Q. And that has been true for many, many years,

hasn't it? Long prior to the Gravell patent? A. Oh, yes.

Mr. Owen: At this point, Your Honor, I wish to read the Interstate Commerce Commission regulations for transportation of explosives and other dangerous articles by freight, including specifications for shipping containers. This is Freight Tariff No. 4 issued January 6, 1941, effective January 7, 1941. On page 94, Section 272(a) it reads as follows:

"Sulfuric acid (oleum, oil of vitriol, etc.) must be packed in specification containers as follows:

"(b) Spec. 15A, 15B, 15C, 16A, or 19A.—Wooden boxes with glass or earthenware inside containers not over 1 gallon each, except that inside containers up to 3 gallons each are authorized when only one is packed in each outside container.

"(c) Spec. 31.—Jugs in tubs. Jugs not over 2 gallons each and only one jug in each tub.

"(d) Spec. 11A or 11B.—Wooden barrels or kegs with glass or earthenware inside containers not over 2 gallons each.

"(e) Spec. 1A or 1C.—Carboys in boxes or kegs; authorized only for acid of not over 100.5 per cent H_2SO_4.

"(f) Spec. 103A.—Tank cars.

"(g) Spec. 5A.—Metal barrels or drums only for acid of 1.81 specific gravity (65° Baume) or greater strength or when the strength of the acid is 60-65° Baume and the acid has been treated with an inhibitor that renders its corrosive effects on steel no greater than 66° Baume commercial sulfuric acid."

The rest of the section relates to lead lined metal barrels, rubber lined metal barrels or drums, in which we are not particularly interested, and so I will not read it.

Mr. Owen: Now, in view of those specifications, would you say that 66° Baume sulfuric acid would be a safe standard of comparison for determining whether or not it would be safe to store or ship an acid in a steel drum within the meaning of the Gravell patent? A. The person or persons who wrote that specification appeared to think so. I don't

necessarily agree with them. I feel that 66° Baume sulfuric acid is very slightly corrosive, indeed, to most steel. A somewhat higher degree of corrosion might be permissible.

Mr. Owen: Now I wish to read the specifications for the shipment of hydrochloric acid. Reading from page 91, Section 263(a) "(1) Hydrochloric (muriatic) acid and hydrochloric acid mixtures must be packed in specification containers as follows:

"(a) (2) Spec. 15A, 15B, 15C, 16A, or 19A.—Wooden boxes with glass or earthenware inside containers not over 1 gallon each, except that inside containers up to 3 gallons each are authorized when only one is packed in each outside container.

"Wooden boxes with glass or earthenware inside containers not over 1 gallon each, except that inside containers up to 3 gallons each are authorized when only one is packed in each outside container.

"(a) (3) Spec. 5D.—Rubber-lined metal barrels or drums. Any such container that shows evidence of damage must be tested, before shipment, for defect in lining in the manner prescribed in spec. 5D."

And the next one:

(Reading): "(a) (4) Spec. 43A.—Rubber drums.

"(a) (5) Spec. 11A or 11B.—Wooden barrels or kegs with glass or earthenware inside containers not over 2 gallons each.

"(a) (6) Spec. 1A or 1C.—Carboys in boxes or kegs.

"(a) (7) Spec. 10A.—Rubber-lined wooden barrels or kegs.

"(a) (8) Spec. 103B, 108, or 108A.—Tank cars."

Mr. Owen (reading):

"(b) (1) Hydrochloric acid of not over 20 per cent strength (13.25° Baume) and other corrosive liquids containing not over 20 per cent hydrochloric acid in addition to containers prescribed in sec. 263(a) may be shipped in specification container as follows:

"(b) (2) Spec. 10A.—Asphaltum-lined wooden barrels or kegs.

"(c) When hydrochloric acid contains oils or solvents it must not be shipped in containers or tank cars lined with rubber."

That is the end of the specification for hydrochloric acid.

Mr. Owen: I would like to find what those tank car specifications are, Your Honor. While we are waiting for that section of the regulations, I will ask a few questions.

Q. On these foreign shipments that you refer to, am I correct in understanding that the products were those that you have previously described as Rodine, Murodine, Deoxidine, Deoxylyte? A. I think that includes all the important ones. Not Murodine, we do not ship that in steel.

Q. Oh, you do not ship that on long journeys? A. We do not ship it at all in steel.

Q. But you do ship Rodine, the Deoxylyte, and the Deoxidine, is that right? A. Yes. Sometimes, Mr. Owen, there are special regulations by the shipping companies as to what kind of packages they will take the stuff in, so you have to pack it that way, but I know we have shipped all those products in steel on boats.

Mr. Owen: Well, Your Honor, Mr. Conner gives me this information which he has taken from these freight regulations, and which we will confirm later. We haven't been able to locate the place in them. He says that Tank Specification No. 103B is rubber lined; Tank Specification No. 108 is rubber lined; Tank Specification 108A is asphaltum lined. That is in connection with the shipment of hydrochloric acid.

The Court: By whom?

Mr. Owen: Anybody in Interstate Commerce.

The Court: That is just what you read to me.

Mr. Owen: I read to you in one paragraph, which simply specified these three tanks without telling what they were; specified them by number. I undertook to locate in the regulations the specifications for those particular numbered tanks. I haven't been able to find that but Mr. Conner tells me he has looked it up and that Tank 103B is

rubber lined, Tank No. 108 is a rubber lined tank, and Tank No. 108A is asphaltum lined. Those are acceptable for the shipment of hydrochloric acid.

Mr. Owen: I want to ask you again, Mr. Douty—I think I have referred to it once, but I am not entirely clear—if it is not a fact that the products your company manufactures and sells and which you have named, are compounds containing acids and not acids themselves? In other words, instead of shipping acids you are shipping compounds containing acids; that is right, isn't it? A. Well, I don't really recognize any distinction, but for the sake of clarity I will say that we have not, to my knowledge, shipped any material marked such and such kind of acid. We have shipped materials marked Deoxidine or Rodine or what they may be.

The Court: Well, is it inhibited acid or is it just the inhibitor? A. Well, Your Honor, it is both ways.

The Court: I see. All right. You sell both the inhibitor for people to put in acid, and you sell it all ready for use. A. That is right. But in that case we haven't sold it as inhibited acid, Your Honor. We haven't named it inhibited acid or whichever. It had some trade name.

Mr. Owen: You don't sell any acid as such, do you; for instance, you don't advertise that you manufacture and sell phosphoric acid, hydrochloric acid, or any other acid? A. I don't think we advertise it, but we do sell phosphoric acid as such; we have a plant for producing it and we sold that, and what we buy from other sources.

Q. How do you ship that phosphoric acid. A. In all packages, not steel.

Q. In glass, rubber-lined tanks, and so forth? A. Yes, sir.

The Court: Do you sell hydrochloric acid as such too? A. No, Your Honor. We have shipped inhibited hydrochloric acid under the name of Rodine, for cleaning out radiators.

Mr. Owen: Regarding the tank car specifications for the shipment of hydrochloric acid, which were referred to

in the quotation I read from the regulations as specifications 103, 108 and 108A for tank cars, I have here a copy of the Interstate Commerce Commission regulations, dated September, 1930, which contains the specifications for those three types of tank cars, and they are rather lengthy. The one for tank car 103 is found beginning page 399; tank car 108 begins on page 432, and 108A begins on page 435, and I find that the first two are rubber-lined cars and the other is an asphalt-lined car.

Stipulation re Previous Litigation	13, 14
Offers of Exhibits	1403, 1408, 1425, 1434
Proceedings on Settlement of Findings of Fact	1435–1477
Findings of Fact	1478–1491
Conclusions of Law	1492
Decree	1492–1493
Notice of Appeal	1494
Orders Extending Time	1494–1495
Stipulation Extending Time	1496
Statement of Points on Which Appellant Will Rely	1497–1500
Stipulation Approving Printed Record on Appeal	2048

PRIMA FACIE WITNESSES

INDEX TO EXHIBITS

Plaintiff's Exhibits

Exhibit Number		Pages Identified	Pages Printed
1	Grebe-Sanford patent in suit 1,877,504	15	1501
2	Grebe patent 1,916,122	15	1504
3	Grebe-Stoesser patent 1,998,756	15	1509
4	Chamberlain patent 2,024,718	15	1512
7	Bureau of Mines Bulletin 148	29	Vol. I, 29
9	Chart of patent applications involving use of acid in wells, filed from 1866 to 1939	63	1515
9½	Revision of Exhibit 9	80	1516
10	Chart entitled "Streams of Knowledge"	65	1517
10½	Prior Art Patents and Publications		1518–88
	Sherwood 57,982	65	1518
	Roberts 59,936	46	1521
	Dickey 106,793	47	1525
	Roberts 119,884	49	1528
	Looney 139,010	66	1530
	Aiken 288,150	86	1531
	Ball 670,577	70	1533
	Mitchell 825,745	50	1537
	Dunn 1,067,868	50	1541
	Muehl 1,410,827	71	1546
	Lake et al. 1,498,045	73	1549
	Tilton 1,608,869	74	1552
	Atkinson 1,651,311	53	1558
	Ranney et al. 1,806,499	75	1565
	Bowman 1,809,546	77	1570
	Young 1,858,847	55	1575
	British Patent 158,768	94	1578
	Millon article (1845)	83	1581
	Conroy article (1901)	87	1584
	Watts article (1912)	89	1587
	Corbett article (1918)	93	1588
12	Summary of Dow Shipments of acid with inhibitors February 11 to November 10, 1932	113	1591–96
13	Letters, dated June 13, 1932, to January 19, 1933, from oil industry inquiring about new Dow process of acid treatments for oil wells	148	1597–1625
14	Item in Midland paper regarding new Dow well treating process, dated June 9, 1932	148	1626

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
19	First invoice of defendant for acidizing well, dated March 11, 1935	248	1627
20	Second invoice of defendant for acidizing well, dated May 25, 1935	248	1628
21	Third invoice of defendant for acidizing well, dated May 25, 1935	248	1628
23	Purchase order from Erle P. Halliburton, Inc., dated 5/21/34, for acid treatment of well by Dowell, Inc.	250	1629
26	Ditto, dated October 24, 1934	250	1630
27	Bulk material sales receipt for 1,000 gal. Dowell X acid delivered by Dowell Inc., to Erle P. Halliburton, Inc., dated November 9, 1934	250	1631
31	Agreement dated March 15, 1934, for acidizing two wells by Dowell, Inc., for Steen Drilling, Inc.	251	1632
34	Agreement dated April 20, 1934, for acidizing ten wells by Dowell, Inc., for Steen Drilling, Inc., or Erle P. Halliburton, Inc.	251	1635
38	Order from Steen Drilling, Inc., dated 3/15/34, for acid treatment by Dowell, Inc.	254	1639
40	Ditto, dated 3/17/34	254	1639
43	Ditto, dated 4/20/34	254	1640
46	Purchase order from Erle P. Halliburton, Inc., dated 5/9/34, for 2,000 gal. acid job by Dowell, Inc.	254	1640
52	Receipt, dated 7/10/34, for well treatment performed by Dowell, Inc., for Erle P. Halliburton, Inc.	254	1641
54	Ditto, dated 7/24/34	254	1642
57	Ditto, dated 8/15/34	254	1643
59	Ditto, dated 9/16/34	254	1644
60	Purchase order from Steen Drilling, Inc., dated 9/16/34, for 1,500 gal. acid job by Dowell, Inc.	254	1645
62	Receipt, dated 10/24/34, for well treatment performed by Dowell, Inc., for Erle P. Halliburton, Inc.	254	1646
64	Ditto, dated 11/14/34	254	1647
66	Ditto, dated 12/19/34	254	1648
67	Stipulation re testimony of R. E. Heithecker.	213	Vol. I, 213
68	Stipulation re testimony of H. C. Miller	235	Vol. I, 235

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
71	Sketches of defendant's truck tank...	262	1649
93	Article in Oil City Derrick of October 10, 1895, entitled "A Great Discovery," reporting acid treatment of well by Frasch and Van Dyke.....	1194A	1651–54
94	Table of Dowell, Inc., statistics showing growth from November 10, 1932, to 1940, inclusive. (See also Plaintiff's Exhibit 232.).....	161	1655
99	Well completion data Greendale (Michigan) oil field.....	168	Vol. I, 168
142	Carnegie Library Card cataloging available issues of Oil City Derrick...	1194A	1656
143	Item in Oil City Derrick for October 28, 1895, reporting acid treatment of wells by Frasch and Van Dyke.....	1194A	1656
144	Ditto, for November 9, 1895.....	1194A	1657
145	Ditto, for January 15, 1896.....	1194A	1658
146	Ditto, for February 20, 1896.....	1194A	1659
147	Ditto, for February 22, 1896.....	1194A	1661
148	Ditto, for March 26, 1896.....	1194A	1661
149	Ditto, for August 10, 1897.....	1194A	1663
150	Stipulation re Williams Bros. record..	13	Vol. I, 13
153	Gypsy Oil Company correspondence and reports re removal of "Gyp" scale and prevention of formation of "Gyp" in oil wells of the Glenpool, Okla., field	1087	1664–1704
154	Bartell Table showing results of corrosion tests with defendant's truck (treating) acids on strap iron test pieces	329	1705
155	Ditto, showing results on test pieces of oil well pipe from National Supply Co.	333	1706
156	Ditto, showing results on test pieces of oil well pipe from Oil Well Supply Co.	333	1707
157	Ditto, showing results on test pieces of oil well pipe from Atha Supply Co..	334	1708
158	Bartell Table showing results of corrosion tests with defendant's storage acids on strap iron test pieces.....	345	1709
159	Ditto, showing results on test pieces of oil well pipe from National Supply Co.	345	1710

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
160	Bartell Table showing analyses of defendant's truck (treating) acid samples	376	1711
161	Bartell Table showing analyses of acid samples taken from defendant's storage tanks	378	1712
162	Bartell Table showing analyses of acid samples taken from defendant's storage tanks and diluted to strength of defendant's truck (treating) acid samples	379	1712
163	Bartell Table showing content of copper, lead and iron in acid used by defendant in treating Zahn well, and same as to acid from defendant's storage tanks	380	1713
164	Bartell Table showing content of copper, lead and iron in acid used by defendant in treating Stella Wilcox well, and same as to acid from defendant's storage tanks	383	1714
165	Bartell Table showing content of copper, lead and iron in acid used by defendant in treating Crawford well, and same as to acid from defendant's storage tanks	384	1715
166	Bartell Table showing results of corrosion tests using c. p. (chemically pure) hydrochloric acid solution containing different amounts of copper, lead and iron	394	1716
167	Bartell Table showing effect of agitation and increased quantity of acid on corrosiveness of acid solutions containing different amounts of copper, lead and iron	407	1719
169	Bartell Table showing amounts of copper, lead and iron in defendant's truck (treating) tank acids and storage tank acids	424	1720
170	Bartell's chart showing effect of adding copper, lead and iron to 15.1% c. p. hydrochloric acid	428	1721

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
171	Bartell Table showing percentage reduction in corrosiveness of hydrochloric acid resulting from addition of different inhibitors named in Grebe-Sanford patent	451	1723
172	Data showing dates when samples of defendant's treating and storage acids were taken by plaintiff and dates of receipt of acid by defendant	494	1724
173A	Prutton Table showing results of small scale tests of corrosiveness of hydrochloric acid containing different amounts of iron, lead and copper	516	1726
173B	Table comparing results of some of tests shown in Exhibit 173A	516	1727
173C	Ditto	516	1727
173D	Ditto, and description of tests, materials and equipment used and explanation of tables	516	1728–33
176	Prutton Table showing amount of iron dissolved from Series 1 oil well tubing in large scale Run 1A using 15% commercial HCl	508	1734
177	Ditto re Run 1AA	515	1735
178	Ditto re Run 2A using Series 2 tubing	515	1736
179	Ditto re Run 2C using Series 2 tubing	515	1737
180	Ditto re Run 1B using Series 1 tubing and 15% commercial HCl containing small amounts of copper, lead and iron chlorides	517	1738
181	Ditto re Run 2B. Similar to Run 1B, but with Series 2 tubing	517	1739
182	Ditto re Run 2D. Similar to Run 2B, but with different amounts of copper, lead and iron	517	1740
183	Ditto re Run 2E. Similar to Run 2B, but with different amounts of copper, lead and iron	517	1741
184	Prutton's summary and conclusions with respect to runs in Exhibits 176-183	534	1742–45
185	Prutton Tables showing results of Runs 1M, 1N, 2M and 2N, using commercial acid from special tank embodying features of defendant's truck tanks	537	1746–49
	Sketch showing equipment used in Runs 1M, 1N, 2M and 2N	537	1751

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
186	Defendant's booklet re Howco method	587	Vol. II, 587
187	Prutton graph showing results of runs of Exhibits 176-183	602	1752
188	Prutton graph comparing results of Runs 1M, 1N, 2M and 2N (Exhibit 185) with average of Runs 1A, 1AA, 2A and 2C (Exhibits 176-179)	604	1753
189	Prutton graph showing results of tests of 15% c. p. hydrochloric acid with different added amounts of copper, lead and iron	605	1754
192	History of oil development in limestone fields prior to 1932 and history of acidizing in those fields beginning in 1932, prepared by the witness Fitzgerald	178	1755–70
195	Item from Montana Oil & Mining Journal for January 26, 1935, reporting increase of production in Pondera (Montana) field, due to acidizing	186	1770
196	Bulletin of Montana Oil Conservation Board	189	Vol. I, 187
199	Letter, Dow Co. to Oil Makers, 9-23-32	1171	Vol. III, 1172
200	Letter, Grasselli to Oil Makers, 10-14-32	1174	Vol. III, 1174
201	Letter, Grasselli to Oil Makers, 11-1-32	1175	Vol. III, 1175
202	Letter, Grasselli to Oil Makers, 1-26-33	1176	Vol. III, 1178
203	Letter, Grasselli to Oil Makers, 9-15-32	1179	Vol. III, 1179
204	Letter, Oil Makers to Grasselli, 10-8-32	1179	Vol. III, 1180
205	Oil Makers checks to Penn. Salt Co.	1196	Vol. III, 1196
216	Letter, Lee to Oil Makers, 2-7-33	1243	Vol III, 1242
218A-218D	Pages from notebook kept by the witness Sprenger	1257	1772–74
219, 220	Photograph of standing valve and working valve	1268	1775
228	Letter, Prutton to Rebbeck, 1-28-41	799	1776
231A-231J	Dow Company's records of shipments of acid to Pure Oil Company during period from February to May, inclusive, 1932	140	1777–86
232	Table supplementing Exhibit 94	845	1787
233	Summary of well treatments made by licensees of Dow other than Dowell	845	1788

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
234	Sketch and data prepared by Dr. Prutton showing rates of attack on oil well tubing of 15% c. p. hydrochloric acid and of 15% synthetic defendant's treating acid	840	1789
242	Dowell advertisement in Petroleum World, September, 1938	846	1790
243	Ditto for January, 1939	847	1791
245	Dowell, Inc., Service Price Schedule 110.	852	1792
246	Record of shipments of hydrochloric acid and arsenic inhibitor by Dow Company for period January to June, 1932, inclusive	121	1793
305	Affidavit of Robert Quinlan on the first treatment of a Pure Oil Company well with inhibited hydrochloric acid.	1028	1794
328	Table showing results of acid treatments of gas wells by Dowell, Inc., prepared by the witness Lyons	191	1796
329	Ditto, showing additional treatments and data	193	1797
330	Table showing time acid was in tubing in each of 122 acid treatments made by Dowell in Kansas from March to September, 1936, in 97 consecutive Arbuckle dolomite wells	197	1798
331	Data showing average time acid was in tubing in making the 122 treatments itemized in Exhibit 330	197	1799
337	Chart showing combinations possible under claims of Gravell Patent 1,678,775.	1320	1800
343	Alquist Table showing rate of corrosion of mild steel in various concentrations of hydrochloric acid	1365	1801
	Charts forming part of Exhibit 343	1365	1802–03
344	Alquist Table showing acceleration of the rate of corrosion of hydrochloric acid containing an acid regulator caused by the addition of tin, cobalt or nickel	1370	1804
	Chart forming part of Exhibit 344	1370	1805
347	Table supplementing Plaintiff's Exhibit 252	1404	1806
348	Table showing treatments by Dow licensees other than Dowell	1404	1807

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Exhibit Number		Pages Identified	Printed
349	Table showing summary of royalty charged by Dow Company to licensees.	1404	1808
350	Table showing quantities of inhibited acid and other materials used by Dowell, Inc.	1405	1809
350A	Graph illustrating data in Exhibit 350.	1407	1810
351	Acidizing orders, tickets and other data from defendant's files relating to wells at which plaintiff secured samples of defendant's truck (treating) acids	1406	1811–24
354	Dowell advertising data for years 1932 to 1934	1407	1825
355	Photograph of one-half gallon container used in Alquist's tests, and table and graphs showing results of tests.	1376	1827–29
356	Photographs of 10-gallon drum and of equipment used by Alquist in making tests, and tables and graphs showing results of such tests	1380	1830–40
357	Table, graphs and drawing of equipment used by Alquist in making tests showing loss of strength of 15% hydrochloric acid when in contact with iron for different periods up to 24 hours.	1398	1841–46
358	Bartell Table showing summary of corrosion tests of various commercial hydrochloric acids of 15.1% strength.	499	1847
360	Table showing Dowell advertising 1932 to 1940, inclusive	1408	1848
362	Poffenberger's report on acid treatment of Dow Company's brine well No. 77	1418	1849–53
363	Poffenberger's report on acid treatment of Dow Company's brine well No. 80	1418	1854
364	Poffenberger's report on tests of inhibiting value of arsenic compounds in hydrochloric acid	1423	1855
366	Carr and Humphrey patent application for method for increasing fluid production from oil wells	1427	1857–64

All exhibits are printed in Volume IV unless otherwise indicated.

PLAINTIFF'S EXHIBITS

Number Exhibit		Identified	Printed Pages
367	Carr and Humphrey patent application on chemical reagent for use in oil wells	1428	1864–68
368	Carr and Humphrey patent application for method for introducing acid reagents into oil wells by gas pressures	1428	1868–72
369	Agreement between The Dow Chemical Company and The Pure Oil Company dated January 31, 1933	1428	1873–77
370	Agreement between The Dow Chemical Company and The Pure Oil Company dated June 30, 1934	1428	1877–82

DEFENDANT'S EXHIBITS

8	Excerpts from article by R. Van A. Mills, dated December, 1923, entitled "The Paraffin Problem in Oil Wells".	35	1883
72	Letter from M. G. Harper to J. W. Van Dyke, dated December 5, 1895	1033	1884
73	Telegram, Harmon to Van Dyke, dated January 24, 1896	1033	1885
74	Memo from C. F. Lufkin to Van Dyke, undated.	1033	1886
83	Telegram, J. C. Donnell to Van Dyke, dated November 25, 1895		1887
86	Telegram, Harper to Van Dyke, dated December 6, 1895		1887
88	Letter, The Grasselli Chemical Company to Van Dyke, dated July 26, 1895		1888
90	Letter, Herman (Frasch) to Van Dyke, dated September 22, 1895		1889
101	Letter, Harper to Van Dyke, dated December 16, 1895	1033	1890
102	Letter, Harper to Van Dyke, dated December 16, 1895	1047	1891
103	Letter, Ohio Rubber Company to Solar Refining Co., dated September 21, 1895.	1047	1892
104	Letter, Ohio Rubber Company to Solar Refining Co., dated September 25, 1895.		1893
105	Memo re Crossley Well No. 3 of Ohio Oil Company	1047	1894

All exhibits are printed in Volume IV unless otherwise indicated.

DEFENDANT'S EXHIBITS

Exhibit Number		Pages Identified	Printed
108	Letter, Harper to Van Dyke, dated February 5, 1896	1047	1895
109	Correspondence between Lufkin, Van Dyke and Donnell re acid treatments (July, 1895, and February, 1896)	1047	1896
110	Letter, Lufkin to Van Dyke, dated July 29, 1895		1900
111	Letter, Harper to Van Dyke, dated December 2, 1895	1047	1902
112	Letter, Grasselli Chemical Company to Van Dyke, dated November 21, 1895		1903
113	Letter, Van Dyke to Grasselli Chemical Co., dated November 20, 1895		1904
114	Memo dated November 21, 1895		1905
115	Letter, Frasch to Van Dyke, undated		1905
132	Letter, Grasselli Chemical Co. to Van Dyke, dated July 19, 1895		1906
138	Letter, Lufkin to Van Dyke, dated August 2, 1895		1907
151	Report on scale formation in wells by Blaine B. Wescott	1081	1908–21
152	Report by F. W. Karl, dated February 1, 1929, re treatment of William Berryhill Well No. 8	1087	1922
153	Same as Plaintiff's Exhibit 153	1087	1664–1704
191V	Gardner Affidavit	750	Vol. II, 752
221	Letter, Robinson to Prutton, 9-12-39	769	Vol. II, 769
222	Letter, Rebbeck to Prutton, 1-24-41	771	Vol. II, 772
223	Letter, Prutton to Rebbeck, 2-19-41	774	Vol. II, 775

FRANK PALIN SPRUANCE,

testified as follows by deposition:

DIRECT EXAMINATION

My residence is 8204 Cedar Road, Elkins Park, and my occupation is vice-president of the American Chemical Paint Company, at Ambler, Pennsylvania. I have been connected with the American Chemical Paint Company since 1920 or '21, in connection principally with sales. I was graduated a mechanical engineer from the University of Pennsylvania but have had very little to do with the technical work of the company. Mr. Douty, and formerly Mr. Gravell, now deceased, have had charge of that work since my connection with the company. Mr. Gravell was president of the company. The company maintains a technical laboratory. It has maintained it since about 1923, when Mr. Douty came with it. Previous to that time Mr. Gravell did all of the development work and all of the chemical work for the company. Mr. Douty organized this laboratory work, under Mr. Gravell's supervision, and has worked very closely with Mr. Gravell in the technical developments. Mr. Gravell has been dead since December of 1939. During the first few years the company had the technical laboratory there were only two on the technical staff, Mr. Gravell and Mr. Douty, and they worked side by side and hand in hand, collaborated very closely. That would apply up to the year that Mr. Gravell died. Mr. Douty's official title was chief chemist, and has been at all times. My duties at times have had to do with the sales end.

The principal business of the American Chemical Paint Company when I first became connected with it was the manufacture and sale of acid cleaners, for preparing metals for painting, and in addition, soldering fluxes used on metal, and in addition to that we had a product known as

Lithoform, which was used to coat galvanized iron so that the paint would adhere to it. The Deoxidine was the only one of those products that contained acid. It contained phosphoric acid. It was originally shipped in wooden barrels with a rubber lining. We used the rubber lining because it was the only container we found that we could suitably carry the Deoxidine in, and even so, we had a great deal of trouble with the Deoxidine leaking out through pinholes in the rubber and getting onto the hoops and corroding the hoops, and the barrel went to pieces. Without the rubber lining that would have happened very, very quickly. That method—I don't remember exactly the date, but I think that that continued until about 1926. We continued to manufacture and sell Deoxidine after that date and shipped it in steel drums, and still do.

As to other acid products our company now manufactures inhibitors, the trade name of which is Rodine. We have another inhibitor of the Rodine type, which we designate as Murodine. Sulphuric and muriatic acid are used in those products, but both acids are not used in the same product. We would have muriatic acid in the case of one particular Rodine, and we would have sulphuric acid in the case of other Rodines, but I know of none in which both acids are used. We have sold Rodine—I have forgotten the date, Mr. Douty can give you the dates more accurately that I can, but I would say from about 1923 on. Murodine we first made and sold about 1926 or '27. I think muriatic acid was used in Murodine. That is still manufactured and sold. In some Rodines we use sulphuric acid as an ingredient and in other Rodines we use muriatic acid or hydrochloric acid as an ingredient, and in Murodine we use only the hydrochloric. But let me make this explanation, that I wouldn't want to be held too definitely to the formulation of these materials. Now, there may be some small amount of one or the other acid in one of these materials which may come in in the process of manufacture, but the Murodine, as I remember it, is predominantly muriatic acid.

We manufacture phosphoric acid ourselves, at Newcastle, Delaware, and ship it in rubber lined barrels. We ship our Rodine in steel drums and we ship our Murodine I think, in wood barrels—for a reason. We have always shipped our Rodine in steel drums.

We first began to manufacture and sell Rodine about '23 or '24—now, Mr. Douty has the dates on that more accurately. That is my recollection, '23 or '24. Rodine was used to prevent acid dissolving metal. It was used in the steel industry in a process which is known as pickling, where steel is introduced into diluted acids for the purpose of removing scale, scale being the black oxides of iron. It is also used to remove rust, in some cases. There are some plants where muriatic acid is used. Sulphuric acid is preferable, principally on account of the cost, in the pickling process in the steel mills. Rodine is placed in either one of those acids, according to whichever one is used. Sulphuric acid is used in the pickling industry in strengths which will vary from two per cent to ten per cent by volume and the rest of the volume is water except for the small quantity of Rodine that is also added. The Rodine concentration will vary from one-eighth per cent to one per cent, and that percentage is based on the volume of the undiluted acid, and those percentages which I have just stipulated are such as are used in the pickling in steel mills for the removal of scale, and in miscellaneous industries for the removal of scale or rust. The undiluted sulphuric acid which I have referred to above is either 60 or 66 degree Baume, and the sulphuric acid solution used in pickling in the steel mills is made up of from two to ten per cent of sulphuric acid of from sixty degrees to sixty-six degrees Baume. To that solution there is added from one-eighth of a per cent to one per cent of Rodine.

Hydrochloric acid is used much stronger than sulphuric acid in the pickling industry. The strength of the solutions will vary, and commercially they might be used from twenty per cent to one hundred per cent by volume of the commercial muriatic acid which is either 18 degrees Baume or

20 degrees Baume. Sometimes that 18 degree or 20 degree Baume hydrochloric acid is used undiluted. It is used in diluted solutions perhaps in the same plant. The strength of the acid is the factor which controls the speed of removing scale or removing rust, or removing lime deposits, or removing whatever is to be removed. The stronger the acid, the more rapid the action, in most cases. The concentrations of Rodine or Murodine in muriatic acid pickling solutions will vary widely, but they will range from one-eighth to three per cent by volume of the undiluted commercial muriatic acid.

Our company has carried on a pickling business of its own and we conduct such business now. My testimony regarding the acids used in pickling, and the strengths of acids used, and the proportions of Rodine or Murodine used, is based on operations which we have controlled or advised in the steel mills, in tremendously big proportions, in large quantities, in many mills. My testimony applies to the pickling operations as commonly carried on by the big mills, and we use Rodine and the acid solutions in the same general way in our own pickling, wherever we do it here, and we have generally used it whenever we did, and that, as I said before, has gone back to time immemorial in the history of this company, because we have always had occasion to do some pickling in experimenting with other processes of treating metals.

There are many objects in pickling iron or steel. First, because of the very large tonnage and very general application, I would place the object of pickling as the removal of mill scale, as it is called. Mill scale is the oxide coating which forms on steel when it is heated. This scale must be removed before the steel can be subsequently fabricated. Another purpose for pickling is to remove rust. The effect is much the same, and the use of the solution is much the same as that in pickling for the purpose of removing scale. Another use is for the removal of calcareous deposits from equipment, such as bottle and can washing machines, automobile radiators, wells. The only thing that I would class

as actually the pickling art is the removal of mill scale and the removal of rust. The sheet metal as it comes from the steel mills does not usually have a calcareous deposit on it, and pickling as I have defined it is not usually intended to remove calcareous deposits, but there are times when steel comes from the mill with a coating of lime on it, and with that lime is rust, and in that case the steel is pickled, and the lime and the rust are both removed. If there is any calcareous material on the steel the pickling operation would remove it. I don't know how lime would get on the steel before it comes to the pickling vat, but I know how it would get on the steel after it has gone through the pickling vat, and that is where it is put on, they use the lime to neutralize the spent acid, and a coating of lime and calcium carbonate and probably calcium sulphate is left on the steel. They re-pickle it to remove that material in the fabricating plants. Steel is pickled many times. All steel is pickled many times. Lime is not used in the pickling solution; it is used in a separate wash tank, as a neutralizer to wash the acid off the steel after it is pickled. What they use after the pickling operation which results in putting a lime coating on the pickled material is powdered lime. Just dry powder.

Q. You say you don't know in what form the lime is used for this purpose, except that it is in powder form? A. That is right.

Q. And that is all you know about it? A. That is all I know about it.

My principal reason for knowing that these pickled sheets, after they are treated with the powdered lime, contain a calcareous deposit, is the method of deduction. You have heard that you can't make purses out of sows' ears, and you can't get anything except lime coatings out of a solution that contains lime. In pickling sheets of iron or steel it is desirable to leave the surfaces clean and free from any other materials.

In the pickling operation the Rodine is used to prevent the acid unnecessarily dissolving the metal. In other words,

it is used to protect the metal against acid attack. This statement is made having in mind the addition of the Rodine to the pickling solution in the mills. As to Murodine, this material has not been offered for the pickling industry. That material was developed solely and entirely for use with muriatic acid, as this was used in the oil industry for cleaning oil wells. The purpose of Rodine is to prevent acid attacking metal.

We sell Murodine for the purpose of preventing the attack of acids on metals. That is not sold in the pickling industry, but its purpose is the same purpose. It is not used in the pickling industry under that name. Murodine is of the same nature as our Rodines, but Murodine was so named because it was used specifically in muriatic acid. The bulk of the pickling that we are serving is sulphuric acid and Murodine as compounded is not suitable for use with sulphuric acid. We sell our Rodine and our Murodine to different classes of customers. We do not sell them to the same customer. We sold Murodine to the oil industry, and to no other industry. We sell Rodine to the pickling industry and now to no other, but we did sell Rodine to the oil industry in the early days. By the early days I refer to 1926, '27, '28, somewhere along there.

Mr. Owen: Do you know of your own knowledge the uses for which your Rodine was used in the oil industry in 1926 or 1927 or thereabouts? A. It was used to remove calcareous deposits from oil wells, to increase the flow of oil into the well, and without doing unusual harm to the tubing and casing.

Q. You are testifying of your own knowledge, now? A. I have never seen it so used, but I have heard of its use many, many times.

Mr. Owen: I move to strike out the last two preceding answers as irresponsive and volunteered.

Mr. Owen: Now, I will ask you again, Mr. Spruance, and I warn you that I want your own knowledge and not what someone else told you, do you know of any instance where Rodine was used in the oil industry for any purpose

prior to 1932, and if it was so used, in exactly what way was it used? A. You put me in an embarrassing position, because, as I said before, I never saw it so introduced, but I am just as sure as to how it was used,—

Q. No, no,—

Mr. Richmond: No, just a minute. Go ahead, let the witness answer, and you can move to strike out.

Mr. Owen: I want the witness to confine himself to the question. This witness is not a witness on behalf of the plaintiff in the sense that he is a biased party for the plaintiff. He is really a party-defendant to this case, because it was his company which developed the Gravell patent and which sold it to your company to bring suit against us. Therefore, this witness is not permitted or should not be permitted to volunteer testimony, and he should not be permitted to testify to anything that he does not know of his own knowledge.

Mr. Richmond: Well, he has a right to testify as an official of the American Chemical Paint Company what he knows from its records and from his position as the head of sales of that company.

Mr. Owen: If the witness can—

Mr. Richmond: And I certainly object to your lecturing the witness. You ask him the questions, and if he doesn't give you the answers, why, you have a proper way to get them.

Mr. Owen: Now, I will ask you once more, Mr. Spruance, and in all good nature,— A. I am going to answer you in good nature, too.

(Continued): —If you know of your own knowledge of the actual use of Rodine in an oil well prior to 1932. A. I will again say that I have never seen Rodine put into an oil well for the purpose described, but I will say—

Mr. Owen: Now, I object—

Mr. Richmond: Go ahead. I object to your cutting the witness off.

Mr. Owen: I object to any further statement—

Mr. Richmond: This witness has a right to complete his answer.

Mr. Owen: —unless it is in response to the question.

Mr. Richmond: No, you can move to strike it out. Go ahead and continue your answer.

Mr. Owen: I don't want the witness to state what someone else told him.

Mr. Richmond: Now, complete your answer, Mr. Spruance.

The Witness: This is off the record.

(Discussion off the record.)

Mr. Richmond: Well, I ask that you finish your answer, and then let counsel move to strike it out if he wishes. Go ahead and say what you have to say.

Mr. Owen: Confine yourself to what you know, Mr. Spruance.

The Witness: I am perfectly sure that the—

Mr. Owen: I object to that.

The Witness: —that the Rodine—

Mr. Owen: I object to that, unless you know.

Mr. Richmond: Well, you have objected. Now, let the witness answer, and then move to strike it out as not responsive.

The Witness: —that the Rodine was used for the purpose of protecting the metal equipment in oil wells, because we were in the business of supplying materials for that very purpose, and the people who had the problem of protecting metal in oil wells came to us for relief.

Mr. Owen: I move to strike out that portion of the answer as irresponsive.

Mr. Owen: Now, I will ask you whether of your own knowledge you know of any instance where Murodine was placed in an oil well prior to 1932.

Mr. Richmond: Well, I will stipulate that was not ever used prior to 1932. Go ahead. A. It was not.

Mr. Owen: As your testimony now stands it is that you do not know when Murodine was first placed on the market. That is correct, is it? A. I don't recall the exact date, no.

Q. And that you don't know when Rodine was first

sold for use in the oil industry? A. I don't know the date of that.

CROSS EXAMINATION

I don't know exactly when the American Chemical Paint Company first sold a Rodine to be used as an inhibitor for hydrochloric acid that was to be used in an oil well, but I would say it was somewhere around 1925 or 1926 or 1927. We sold some to the Gulf and we sold some to the Gypsy oil companies.

Referring to a photostatic copy of an order from the Gypsy Oil Company, number 4069, dated September 19, 1928, I feel sure our company received the original of that order because I know we shipped Rodine to the Gypsy Oil Company. There was fifty-two gallons shipped, in a fifty-two-gallon steel drum.

Referring to a photostatic copy of Gypsy Oil Company order number 69422, dated September 23, 1929, with the received stamp of October 16, 1929, thereon for one ten-gallon drum of Rodine Number 2, I recognize that as an order that we received from the Gypsy Oil Company. I can't identify it exactly as to that date, but I know that we shipped Rodine at that time to the Gypsy Company.

Referring to order number 4069 of the Gypsy Oil Company, the Rodine that was called for is Rodine Number 2.

Referring to a photostatic copy of Gypsy Oil Company order number 117624, of August 14, 1930, I don't know whether it is '29 or '30, I recognize that as an order that we received from the Gypsy Oil Company for ten gallons of Number 2 Rodine. That was filled by our company.

Referring to what appears to be an invoice of the American Chemical Paint Company to the Gypsy Oil Company, at Pittsburgh, Pennsylvania, for ten gallons of Number 2 Rodine shipped in a ten-gallon drum, and dated the 12th, looks like '29, I can't make out the date, that is our company's invoice to the Gypsy Oil Company for the shipment to them of Rodine Number 2.

At the time of these four documents that have been called to my attention, my position with the American Chemical Paint Company was vice-president in charge of sales. The company had salesmen under my direction. We had salesmen in Pittsburgh, we had salesmen in Detroit, we had salesmen in Chicago, we had salesmen in the East. Our salesman at Pittsburgh was William S. Dietrich, who now resides in a suburb of Philadelphia. He was the salesman who would have made these sales to the Gypsy and to the Gulf that I have mentioned. He reported to me the purpose for which the Rodine was to be used. He told me that the Rodine had been found very effective as an addition to muriatic acid for the treatment of wells. He was working in collaboration with a Mr. Wescott, who was at that time associated with the Gulf Research. Mr. Wescott had tested the Rodine, and Mr. Dietrich informed me that Mr. Wescott had advised the various branches that Rodine was an effective material to prevent the action of acid on tubings and casings in acidizing wells, and that he had accordingly recommended its use.

Mr. Dietrich at the present time is pensioned. For two years he has been ailing very seriously with coronary thrombosis. He is confined to his bed most of the time and is not able to do any work at all, as a result of which we retired him on a very fair remuneration, and he is living as long as he will live without doing any work at all. His condition as to being able to appear in court I would say is hopeless. He can't even appear downstairs most of the time.

Since those first sales of Rodine Number 2 the American Chemical Paint Company has had Rodine Number 2 or its equivalent on sale for the purpose of removing calcareous deposits in oil wells. Our company has sold its Rodine or Murodine to the plaintiff, Dow, or its totally owned subsidiary, Dowell Incorporated. Such sales were made between 1928 and I would say 1938. I haven't got the exact dates of any sales to Dowell. I have got some figures here, but I can look that up. I think we sold Dowell

Murodine during the years 1936 and 1937. I do not know how much those sales amounted to, but I think I can find out.

Mr. Richmond: Now, can you give me, as briefly as possible, by years, if you would rather, the amount of sales of Rodines, Deoxidines and Murodines since you started making those articles, when they contained arsenic? A. I don't know when they first contained arsenic, but I am sure that is in the records in Douty's testimony; because I wouldn't be too accurate about the date.

1923, we sold approximately $250,595 worth of Deoxidine and $4,034 worth of Rodine. In 1924 we sold $209,061 worth of Deoxidine, and $14,757 worth of Rodine. In 1925 we sold $558,412 worth of Deoxidine, and $105,125 worth of Rodine. 1926, $735,950 worth of Deoxidine, and $133,440 worth of Rodine. In 1927, $901,559 worth of Deoxidine and $152,066 worth of Rodine. In 1928, $1,060,006 worth of Deoxidine, and $240,589 worth of Rodine. In 1929, $1,070,130 worth of Deoxidine, and $332,678 worth of Rodine. In 1930 we sold $591,627 worth of Deoxidine and $242,782 worth of Rodine. In 1931 we sold $230,557 worth of Deoxidine, and $125,712 worth of Rodine. In 1932, $114,477 Deoxidine, and $104,269 Rodine. In 1933, $156,648 Deoxidine, and $202,027 worth of Rodine. In 1934, $200,738 worth of Deoxidine, and $212,036 worth of Rodine. In 1935, $198,956, Deoxidine, and $283,878 of Rodine. In 1936, $223,493, Deoxidine, and $343,055 worth of Rodine. In 1937, $226,368 Deoxidine, and $325,845, Rodine. In 1938, $142,619, Deoxidine, and $188,721, Rodine. In 1939, $161,142, Deoxidine, and $260,656, Rodine. They are figures that are quite approximate—they are taken from a sales curve, they may be off in a few dollars or a few hundred dollars, but the volume is about right.

Mr. Owen: These figures which you have given include all sales of all Rodines of the various numbers which you manufactured? A. That is correct.

Q. Are you able to separate these figures and show what amounts of the different Rodines were sold during

each year? A. Not without a great deal of trouble. I should say this, that in the early days we had one Rodine or two Rodines, they were liquid—they were arsenic Rodines.

Q. And did you sell Deoxidines under different numbers and formulas? A. Yes, but it was about, I would say, about ninety-five per cent one kind; that is, there were a few special Deoxidines sold in very small quantities for certain specific customers, but the bulk of it was the standard grade.

Mr. Owen: I object to the figures with reference to Rodine unless they are separated into the different Rodine numbers. In bulk they don't mean anything, in my opinion.

Mr. Richmond: The Rodines, though, all contained—all the liquid Rodines contained arsenic? A. That is correct.

Mr. Owen: While we are on this question I think I should dispose of it. Do those figures that you have given for Rodines include any solid or powdered Rodines? A. In the later years, but not in the earlier years.

Q. In what years? A. Mr. Douty has given you the formula for 106 Rodine, which was our first powdered Rodine.

Q. And the sales of powdered Rodines are included in these figures you have given? A. In the later years, yes.

Mr. Owen: I object to the answer in so far as it relates to Rodines on the ground that it is indefinite, and does not set forth the Rodines which might be construed as coming under the Gravell patent in suit.

Mr. Richmond: Mr. Spruance, you have now, have you, before you the date of the first sale to Dow Chemical Company? A. I do. Of a Rodine, first sale is 4th month, 19th, 1935. I don't know what number it is now. It is Rodine. The first sale to Dowell Incorporated was 4th month, 19th, 1935. I have records of sales of Murodine to Dowell Incorporated here for the years 1935, 1936 and 1937. The sales to the Dowell Incorporated of Murodine for the year 1935 were $3,000. For 1936, $3600. For 1937, $232.50.

In the years 1935, '6 and '7, the total amount is $6,832.50. I haven't differentiated between Dow and Dowell. These figures cover both. I do not know why Dow Chemical Company and Dowell Incorporated quit purchasing Murodine from our company.

REDIRECT EXAMINATION

The figure of $6,832.50 which I gave for the total sales to Dowell and Dow covers all sales of our products to both of those companies during the years I mentioned. I cannot from the meager records I have before me, separate the Rodine sales from the Murodine sales or the different Rodines. I would say that they would include not over one Rodine and one Murodine. My personal recollection is that it was all Murodine 101. My recollection is that there was no Rodine. The $6,832.50 are sales of Murodine 101, if my recollection is correct.

I have no information regarding the use or uses to which the Gypsy Oil Company put the Rodine which it purchased from us, other than what appears on the orders themselves or what I said our salesman Dietrich told me. I have no personal information regarding the use to which that material was put.

The only sale of our materials to the Dow Chemical Company or Dowell Incorporated during those years other than Murodine would have been Rodine, and that is where my memory is not completely accurate as to whether it was Rodine and when it changed from Rodine to Murodine, but it was either Rodine Number 4, or Rodine Number 40, or it was Murodine Number 101.

RECROSS EXAMINATION

The information received concerning the Rodine sold to the Gypsy Oil Company was received by me in the regular order of business of the American Chemical Paint Company and in my official capacity as sales manager of that company from a salesman under my direction.

REDIRECT EXAMINATION

On the sales which we made to the Gulf Oil Company I have no information as to the uses to which the products were put other than what appears on the orders or what our salesmen told me other than that the salesmen reported to me that they were used for well cleaning, along with muriatic acid.

Mr. Owen: That was for cleaning "gyp" from the pipe? A. No, that was for increasing the flow of oil in the well.

Mr. Owen: Well, I object to the testimony as hearsay, and renew my motion to strike it from the record.

PAUL W. PITZER,

a witness for defendant, testified by deposition, as follows:

DIRECT EXAMINATION

I live in Breckenridge, Texas, and am in the oil and acidizing business. I am vice president of The Chemical Process Company, which company was incorporated in Texas in 1932 and is in the business of acidizing oil wells. I have been engaged in the business of acidizing oil wells continuously since 1932. The Chemical Process Company was organized for the purpose of acidizing wells. I am also

an oil man and have been for a number of years prior to the organization of The Chemical Process Company. Prior to the organization of that company I and my associates acidized some few oil wells, less than ten, I would say. Some of these wells were my own, the remainder belonged to others. These wells were located in Stephens County, Texas.

Mr. Babcock: Would you please describe briefly just what process or method you have employed in acidizing oil wells. First, state briefly just what you did prior to the organizing of the Chemical Process Company, and then go on and describe in general the process employed by The Chemical Process Company, and if there was any difference in what you did before and after it was organized? A. Why, there was not a bit of difference. On our first treatment we treated a well with 730 gallons of acid. This well belonged to Pitzer and West, that is, myself and partner, who were in the oil business together and worked at that business. Our records show this well was treated on October 13, 1932. We used muriatic acid in treating this well. We ordered it in carboys. I am not positive, but I think it came from the Texas Chemical Company at Houston, Texas. There was no inhibitor or other chemical used in treating this well. We used just straight acid. We mixed it with water and made a fifty-fifty solution. The acid was 18 Baume diluted down to a fifty-fifty solution, which would make a 15 Baume acid. The nature of our treatments after the organization of the Chemical Process Company was the same and is the same today. Our treatments consisted in just putting the acid into the oil well and displacing it either with water or oil to push it back into the formation. The acid was forced into the formation using whatever method was necessary, either from vacuum or from pressure.

Since the organization of The Chemical Process Company to date that company has made approximately fifteen thousand acid treatments to oil wells. This work has been done for practically the entire oil business. I mean by that,

that there are only a few oil companies for whom we have not acid-treated oil wells. We have treated oil wells for all the major oil companies, except The Pure Oil Company. I do not think we have ever treated a well for the Pure.

In these thousands of treatments we have made, we have used an inhibitor on a few wells. We did not use any inhibitor in 1932 or in 1933. We used the last inhibitor on a few wells during the period between the time of the decision in The Dow Chemical Company vs. Williams Brothers Well Treating Corporation suit, between the time it was tried and reversed. It was between the time of the trial of that case and the time the Appellate Court in Denver reversed it. We only used an inhibitor on a few wells between that time and the time it was reversed. It was not our common practice. After the reversal of that case we never used any more inhibitor and we have not used any since that time. We have not used any inhibitor since that case was decided on appeal.

Q. (Exhibiting instrument to witness): I hand you some kind of mimeographed document of 5 pages and will ask you what that is, if you know? A. Well, laying aside a chance for a few mistakes being made, that is supposed to be our business records of the wells we have treated, which we keep.

Q. Did you keep a record of only a part of the wells you treated? A. No, that's supposed to be a complete record through those dates on there, from the time we treated the first well for one year. That's a complete mimeographed copy of the wells we treated the first year.

(The document was offered and received as DX-298.)

The Witness: This document is an entire list of treatments made by the Chemical Process in the Breckenridge, Texas, district. The list is subject to error, but I understand it to be a list of wells which The Chemical Process Company treated on the dates listed. The list gives the amount of acid used on each well, which amount is correct to the best of my recollection. No inhibitor was used in any of these wells listed in DX-298, which list covers wells we

treated from October 13, 1932, to October 13, 1933, during the first year of the existence of The Chemical Process Company. All these wells were located in Texas, and most of them were in the Breckenridge district. There may have been one or two wells in the western part of the state that we treated. We have treated wells in Texas, New Mexico, Kansas, Oklahoma, Louisiana and Arkansas, and we may have treated a few wells in Kentucky. We have treated one or two wells in Nebraska, and I think we have been into Colorado on a treatment or two. This list of well treatments was prepared under my direction. We kept that record of the wells we treated and it is a true record of the wells we treated.

Out of the numerous wells we have treated with acid for the various oil companies, I think we have received one or two complaints due to the corrosion of the iron in wells. I do not regard the use of an inhibitor as necessary to the successful treatment of an oil well.

In the Breckenridge district of Texas there are a number of oil wells, and in general the oil is produced from a lime formation. This field is approximately twenty-one years old, or a little over. In 1932 when we started to acidize oil wells the production of oil from the wells in this field was not as great as it had been in previous years. The production was down to the pumping stage and there was not over one or two wells flowing in the county. A number of the wells were being plugged. Our treatment of these wells with acid was very successful. We helped practically all the wells we treated. As a result the oil operators changed their plans as to what they did with their wells, and immediately after we commenced acidizing it was common practice that the wells be acidized before they were plugged. The acid treatment materially increased the production in this field, and in this district in 1932, I would say, we had anywhere from a two-barrel increase to a hundred-barrel increase per day for each well. I think some of the increases ran even higher than that, but that is just a picture of it.

In the territory where we operate, and have operated, the purpose of the acid treatment is to increase the production of the well. It is our intention that the acid react with the calcium carbonate in the formation from which the oil is produced.

CROSS EXAMINATION

The exact date of incorporation of The Chemical Process Company is October 12, 1932. With respect to the date of the first well treated with acid by The Chemical Process Company, or treated with acid by me and my associate Mr. West, we have two wells we originally treated that are not in the records. One was a well in Eastland County, which we found out later had a sand formation. The next well we treated on October 13, 1932. We treated that well, the Akers No. 1, with 730 gallons of acid.

Mr. West, my associate, and I learned of the acidizing business in 1932 from a couple of fellows, named Markham and Melville, who came here and wanted to make an experiment with acid. I never heard of Dowell Incorporated or The Dow Chemical Company having acidized wells prior to the time we started acidizing wells.

The Chemical Process Company employs a chemist and maintains a complete laboratory. In some cases it is the practice of our company to retain samples of the acid used in treating the wells. Without inquiring, I am unable to say if we have any such samples on hand at present.

We received one or two complaints from operators for whom we had treated wells. These complaints were received on account of corrosive conditions. The acid attacked some parts of the well, or at least the operator so alleged. That is quite common with every operator in the business, or every acidizing company in the business. They run up against things of that kind.

REDIRECT EXAMINATION

Since 1932 our business has increased from year to year. We have had some years that were larger than others, according to how the oil business was going. Of course, in some years there is lots more drilling than in other years. I can say this, that our business has increased in the amount of work being done every year and has grown generally all during these years. We only used an inhibitor on a few wells. We only used it between the time that suit was tried. The business has grown at all times, but we did not use an inhibitor after that suit was reversed.

Mr. Conner: I object to the entire deposition as irrelevant and immaterial. Do you want us to show Chemical Process infringes the Grebe-Sanford patent in order to prevail that Halliburton infringes? That is exactly the position we find ourselves in this morning.

The Court: If you have a patent that is going to apply to the man that just goes and buys the ordinary commercial hydrochloric acid and uses it without putting anything at all in, why all right. You have to show me because I don't think that your patent covers that. I don't think your patent ought to cover a man who just buys ordinary hydrochloric acid and uses it. That is the old patent of 1896, or whatever date it was. That is what he says he does, you have it right there. If you claim he did something else, you ought to prove it.

Mr. Conner: That is just what it comes to. It comes to one thing, and that is this: Do you want plaintiff, in order to prove the defendant infringes, also to show you that Chemical Process infringes?

The Court: I am not considering it on the question of infringement at all. I am considering it on the validity of the patent. Just that claim. It doesn't have anything to do with whether or not the defendant is infringing your patent. I don't see that it even squints that way. I don't see how any judge could possibly get out of that deposition

I have just heard anything about infringement of the patent.

Mr. Conner: I agree with you.

The Court: I am considering it entirely on the question of the validity of your patent.

Mr. Allen Owen: Your Honor, on the question of the validity of the Grebe-Sanford patent, as affected by the testimony of Mr. Pitzer, you, of course, appreciate it is not prior art against Grebe-Sanford.

The Court: Certainly. I am considering it in connection with why this thing has grown as much as it has, how much is due to the patent and how much is due to other things. That is what I am—

Mr. Allen Owen (interposing): You are considering it on the question of utility, then, of the—

The Court (interposing): No. You have brought into this case the revolution of the art by your patent.

Mr. Allen Owen: Yes, sir.

The Court: And I am considering it on whether or not that claim is true. That is what I am considering it on.

Mr. Allen Owen: In order to hold the Grebe-Sanford patent invalid, then, it would be necessary for Your Honor to find it had no utility; is that correct? In considering such testimony as Mr. Pitzer's.

The Court: You are invoking that well-known rule, and Judge McDermott made very great use of it, in taking a doubtful patent and saving it, because that has just torn the world all up and revolutionized the art. That is all he did. And it is a well-known rule that it is a proper thing to do for a patent that has done that. It is right close to the line, it looks as if it doesn't have any validity or wasn't good. That is what Judge McDermott says, at first blush you would think this patent was not any good, because you have just taken two patents and brought them close together. But he goes on and because this patent, by doing that thing, and bringing the two together, he reaches the conclusion that you have revolutionized the art entirely, and that this wonderful growth is due to this patent. And, if he hadn't, he never would have saved the patent. Now,

here is proof to be considered on that thing, as to whether or not you have this patent—this patent has accomplished this thing that will save a doubtful patent. That is all it is for. You bring in the claim and talk about what you have got in this patent, to save it, is that thing to take that out, and Judge McDermott would have beaten you in a minute, I can see that by reading his opinion, he starts right out by saying that.

But he finds that there is this wonderful thing that has been accomplished by the patent, and that is what saves it. Now, I am re-trying it, the very same issue, exactly, as near as I can see it, it is the same issue, but I have got some additional proof and this is some of it, as I understand it. Here is some proof that he didn't have that it is proper to consider.
